AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

*W. Robinson, Author of the "English Flower Garden."*

"You see, sweet maid, we marry  
A gentler scion to the wildest stock;  
And make conceive a bark of baser kind  
By bud of nobler race: This is an art  
Which does mend Nature,—change it rather: but  
The art itself is nature."

*Shakespeare.*

TO

**GEORGE NICHOLSON, A.L.S.**

(Curator of the Royal Gardens, Kew)

*FOR HIS WORK AMONG TREES AND SHRUBS,*

THE FORTY-EIGHTH VOLUME OF "THE GARDEN"

is dedicated,

*W. R., January, 1896.*

INDEX TO VOLUME XLVIII.

(Illustrations in Italics.)

A.

*Abies brachyphylla*, 256; *Douglasi glauca pendula*, 308  
*Aconitum Sanghant*, 365  
*Abutilons* in large conservatories, 291  
*Acacia*, the perpetual-flowering, 172  
*Acanthopanax crinitum*, 411, 453  
*Acanthopanax crinita*, 411, 453  
*Acer Lorbergi*, 390; *rufinerve*, 256  
*Acidanthera bicolor*, 256  
*Actinidia Kolomikta*, 138, 192  
*Achimenes* culture, 167  
*Adiantum Farleyense*, 328, 460; *pedatum*, 136  
*Adiantums* in winter, 499; unhealthy, 212  
*Aerides affine*, 285; *quinquevulnerum*, 96  
*Eschynanthus*, species of, 167  
*Aesculus parviflora*, 128  
*Agapanthus Mooreanus*, 76, 132; the, 76  
*Agave Consideranti*, 117  
*Alberta magna*, 371  
 Allotments, the Manchester Botanic Society and, 249  
*Alberta magna*, 371  
*Almondstony*, notes from, 11, 405  
*Alocasia Lowi grandis*, 169  
*Aloe africana*, 251  
*Alonsoa scutifolia*, 119  
*Alstromerias* from seed, 54  
*Althaea ficifolia*, 171  
*Amaryllis Belkonna*, 232  
*Amasonia pumila*, 252  
*American Light*, 479  
*Ampelopsis muralis*, 318; *Veitchi*, 318  
*Anagallis Monelli*, 255  
*Androsace Charpentieri*, 429; lanuginosa, 114; *sarmentososa*, 215  
*Androsaces*, 175  
*Anemone fulgens*, 113; *japonica Lady Ardian*, 198, 267, 292  
*Anemones* in July and August, 90  
*Angreecum bilobum*, 267, 370; *eburneum*, 508; *Eichlerianum*, 69; *Leonis*, 429; *Scottianum*, 126, 446; *sesquipedale*, 159  
*Anomatheca cruenta*, 22  
*Anthurium bibrasstrum najas*, 20; *lineare foliis variegatis*, 430  
*Anturium Mariae*, 13  
*Antirrhinum*, the white, 102  
*Apothorpe*, Northampton, 495  
*Apothorpe*, Northampton, 495  
*Apheandra nitens*, 109  
*Apoceton distachyon*, 175

*Apple*, a new red *Quarendon*, 431; *Ashmead's Kernel*, 432; *Baumann's Red Reinette*, 254; *Beauty of Bath*, 71; *Benoni*, 195; *Bismarck*, 328; *Blenheim Orange*, 127, 173, 196, 431; *Bramley's Seedling*, 255, 303, 319, 378; *Byford Wonder*, 390; *Cathlin Pippin*, 498; *Cox's Orange*, 194, 235, 303; *Cox's Pomona*, 254; *Crimson Costard*, 193; *crisp*, the, 174, 194; *Domino*, 380; *Duchess of Oldenburg*, 195, 222; *Ducks Bill*, 404; *Duke of Devonshire*, 433; *Earl Morris*, 18; *Egremont Russet*, 331; *Emperor Alexander*, 49, 331; *Empress Alexander*, 5; *Fearn's Pippin*, 432; *Hortland's Pearmain*, 312; *Jefferson*, 432; *Crab John Downie*, 170; *Kerry Pippin*, 312; *Keswick Codlin*, 285; *King of the Pippins*, 253; *Lane's Prince Albert*, 254; *Lord Suffield*, 166; *Magnum Bonum*, 194; *Margil*, 254; *Mere de Menage*, 312; *Mother*, the, 369; *Nanny*, 235; *Newtown Pippin*, 59; *Newtown Pippin*, 174, 254; *Newtown Pippin v. Cox's Orange*, 147; *Pay the Rent*, 348; *Red Astrachan*, 195, 497; *Reinhold*, 210; *Ribston Pippin*, 274, 331, 333; *St. Edmund*, 274; *Stubb's Seedling*, 429; *Crab Transcendant*, 170; *trees*, canker in, 378; *trees* in bloom, 251; *trees*, pruning, 496; *Warner's King*, 379, 434; *White Juneating*, 126; *White Transparent*, 131; *Williams' Favorite*, 170; *Winter Peach*, 498  
*Apples* and canker, 332; and *Pears*, 60; and *Pears*, showy, 465; *tuck garden*, 241; *early dessert*, 233; *foreign*, 478; for *keeping*, 499; *lattering* and *storing*, 173; in *East Anglia*, 234; in *Scotland*, 434; *keeping* in boxes and barrels, 454; *late*, 303; *late flowering*, 312; *marketing*, 93; *new and old*, 173; *notes* on new varieties of, 479; *synonyms* in, 404; *the* *beave* *v.* *t.*, 312, 378; *the* *keeping* *properties* of, 432; *thinning*, 41, 128  
*Apricot Hemskirk*, 358  
*Apricots*, 127; *notes* on, 193, 235  
*Aquilegia chrysantha*, 395  
*Arachnanthe (Vanda) Lowi*, 350  
*Aralia Veitchi*, 300  
*Areca lutescens*, 411  
*Argemone grandiflora*, 192  
*Arnelia cornuta*, 31  
*Ar stolochia triandata*, 489  
*Artichoke*, the *Globe*, 343  
*Arum Lily*, a *double-spathed*, 291

*Arum Lilies*, 54  
*Arundinaria nitida*, 112  
*Asclepias cornuta*, 36; *tuberosa*, 116  
*Ash*, *flowering*, *spikes* of, 286  
*Asparagus* beds, *manuring*, 376; *forcing*, 483; *crispus*, 390; *decumbens*, 75; *late purple Argenteul*, 4; *seed*, *saving*, 376; *Syringeri*, 366  
*Asphodel*, *giant*, at *Preston Hall*, *Dalkeith*, 171  
*Aster Combefishaere*, 354; *Novae-Arglie ruscus*, 324; *Novi-Belgii Ella*, 324; *Novi-Belgii Nancy*, 324; *salicifolius*, 325  
*Asters*, *quilled*, for *cutting*, 278  
*Astilbe astilboides*, 356; *chinensis*, 75, 355; *decandra*, 355; *japonica*, 355, 366; *j. compacta multiflora*, 355; *j. foliis aureo-reticulatis*, 355; *j. foliis purpureis*, 355; *Lemoinei*, 356; *Lomani*, 355; *reticularis*, 355; *rubra*, 355; *Thunbergi*, 355  
*Astilbes*, 355  
*Autumn*, the *advent* of, 275; *tints*, 459  
*Azalea occidentalis*, 49

B.

*Baden-Baden*, *notes* from, 11, 155, 252  
*Balsam*, the *yellow*, 172, 191  
*Bambusa Veitchi*, 459; *and* *others*, 568  
*Bark*, *colour* in, 485  
*Barron*, *Mr. A. F.*, 112, 131, 151, 171, 191, 211, 232, 459; *national testimonial* to, 330, 490  
*Bean*, *Butter*, *Fageolet Roi des Verts*, 131; *Golden Beurre dore Naine*, 131  
*Bean*, *French*, *dwarf*, *early*, *Mangout*, 131; *King of the Greens*, 131; *Longfellow*, 131; *Negro*, *Longpod*, 125; *Northumberland Prolific*, 210; *Sutton's Dwarf Forcing*, 343; *Runner*, *Carter's Elephant*, 158; *Prize-winner*, 259; *Sutton's Mammoth White*, 125; *Sutton's A 1*, 210  
*Beans* for *seed*, 107, 343; *late* *French*, 44; *latest* *French*, 44  
*Beetroot*, *large*, 344, 440; *and* *Carrot* *crops*, 235  
*Begonia*, a *dwarf*, 436; *double*, 252; *Captain Holford*, 291; *carminata*, 31; *disease*, 264, 265, 413; *Emperor*, 100; *Froehel incomparabilis*, 428, 429; *garden*, a, 224; *metallica* and *B. echinosepala*, 251; *Mrs. F. Bostock*, 31; *Mrs. Heal*, 309; *Rajah*, 390; *Success*, 348; *Triomphe de Lorraine*, 349; *Worthiana*, 115

*Belonias and Sonerilas* at *St. Albans*, 447; at *Lewisham*, 218; at *Forest Hill*, 14; *autumn-sown* *tuberosus*, 277; *bearded* and *spotted*, 279; *bedding*, 176; *diseased*, 247; *double-flowered*, 412; *hybrid* *tuberosus-rooted*, 411; in the *flower garden*, 38, 74; *tuberous-rooted*, 292  
*Belgrove*, *plan* of *Mr. Gunbloton's garden* at, 397  
*Belladonna Lily*, the, in *Norfolk*, 386, 435  
*Berberis chinensis* or *Thunbergi*, 329  
*Berberidopsis cordilina*, 329  
*Birch* for *brooms*, 462  
*Bird nuisance*, the, 157, 318, 349  
*Bindweed*, a *rare*, at *Venice*, 118  
*Blackberry White*, *Leberg*, 17

# The GARDEN.

VOL. XLVIII.

## ORCHIDS.

### CATTLEYA SUPERBA.

THERE is no doubt this beautiful Orchid richly deserves its name, being perfectly distinct and making a welcome change from the better-known species of the labiata group. The pseudo-bulbs are nearly erect, from 8 inches to 10 inches in height, furrowed and bronzy in appearance. Each bears a pair of similarly coloured leaves about 4 inches long and thick and leathery in texture. The spikes are produced from between these upon the current year's growth, and each bears usually from two to six flowers; the sepals and petals deep rosy purple, the lip brighter in colour, spreading in front, and with a yellow and white blotch. There is no denying that this is a difficult plant to keep in health for a great number of years, but it might, if properly treated, be made much more of than is usually the case. It is well known that this *Cattleya* enjoys a higher temperature than most other species, and consequently it is too often given heat and moisture in abundance without proper care being taken to ripen and consolidate the growths. Owing to this the plants are very susceptible to checks, more especially during the winter, and frequently fall a prey to the unsightly spot so common to the genus. To make matters worse the plants are kept too dry at the root, causing the pseudo-bulbs to shrivel, thus lowering the vitality of the plants altogether. All *Cattleyas* are difficult to bring round from this state; with *C. superba* it is practically impossible, and the effect of it will be seen in the subsequent weakly growth and puny flower-spikes. Very small plants of this *Cattleya* are not worth having and would be dear at any price, especially if they were bits lopped off old and weakly specimens; but given a healthy imported or established plant and the chances are all in favour of the grower for at least five or six years, after which the plants will probably begin to fail. The longest-lived plants will be those that during the first season take the best hold of the pot, block, or whatever is used for their support, while those that produce flowers before they are well established will in all probability be the first to go back. Personally I prefer pots or baskets to blocks for this species, for the roots are quite as vigorous as those of the

majority of the genus, and if freely produced there need be no fear of getting them to take hold of a little compost. Not much peat should be used in this, and that which is selected must be of the very best without a particle of sand or dust. This fibre used with Sphagnum Moss in the proportion of one to three, and with plenty of crocks and charcoal, will grow it very well, and a thin layer only is required. The plants must be stood in a light position in the warmest house and watered carefully until the roots are running through the compost freely, a full supply being needed when the growth is active and from then until the flowers are past and the pseudo-bulbs well filled out. Then as the temperature is gradually decreased the water supply must be in a like manner lessened, but at no time must the plants be absolutely dry, nor must the temperature during the winter be allowed to go below 60°. A close, moist atmosphere is at this time especially to be avoided, ventilation being given every day when possible without causing a chilly draught. Very little variation is found in the flowers of this *Cattleya*, although some are brighter in colour than others. A white variety has been discovered in Brazil, and one or two others have received varietal names. The present is its usual time of flowering, and if kept in a fairly dry atmosphere while in blossom the blooms last about a month, this treatment serving also to harden the pseudo-bulbs. R.

### LÆLIA PURPURATA.

THE earliest plants of this magnificent Orchid are now in full beauty, and anyone fortunate enough to be possessed of a good stock of plants may look forward to a flowering season extending until the middle of August. This species is most satisfactory in large roomy structures with such kinds as *L. superbiens* and *Cattleya bicolor*. None of these large-growing species thrive so well in narrow, low houses, the foliage being apt to suffer from too much sunlight unless the plants are arranged at least 2 feet from the glass. Shading will prevent this, but if the light is too much subdued the growth is not satisfactory. Where there are only small houses, I would advise growers to arrange the plants as far from the glass as possible and to always ventilate as early in the morning as may be, as the oftener the air of the house is changed the better, this also allowing of the

blinds being kept up a little later. Frequently damping down the pots and occasional light dewings overhead serve also to keep the foliage cool. As soon as this feels warm to the touch the blinds must be let down, otherwise the leaves soon take on an unhealthy yellow tinge, even if not actually scorched. *L. purpurata* thrives in pots in a rough open compost, and in repotting keep the leads as near to the centre of the pot as convenient; this does away with the need of potting for three or four years, provided a little of the compost is removed annually and fresh substituted. Good drainage is essential, and in large pots a smaller one may be inverted over the drainage hole in the bottom, filling up to and around it with potsherds. The pseudo-bulbs being heavy must be firmly staked and tied—at least until the new roots form a natural support. In the best varieties this Orchid grows to a height of 2 feet 6 inches and has fusiform ribbed pseudo-bulbs, each bearing a single leaf. If care is taken not to wet the flowers, they last from three weeks to a month in good condition. *L. purpurata* is a very variable species, some of the better varieties being very expensive, though the commoner, not less beautiful kinds are cheap enough to be within the reach of all who have a glass house.

*L. P. ALBA* is the nearest approach to a white variety and a very chaste and beautiful kind. It occasionally appears among importations of the species and has white sepals and petals. The labellum is also whitish in ground colour with veins of rosy purple.

*L. P. ATRO-PURPUREA* is a deep coloured and handsome form which is in itself variable, as may be seen by comparing the flowers. In this the sepals and petals are deep rose, the lip very deep in colour with an orange-yellow throat.

*L. P. AUREORA* is a singular form that has flowered usually with me at the end of July or early in August. The narrow wavy sepals and petals are of the faintest tinge of rose, while the lip is intense deep purple in front and veined with rose.

*L. P. BRYSIANA* is somewhat similar to the last named, but a superior variety. The sepals and petals are rosy lilac, the lip deep crimson-purple.

*L. P. SCHREDERÆ* is a large nearly white form with a distinctly marked lip. This is, I believe, still rare, though not so much so as formerly.

*L. P. WILLIAMSII* is a magnificent variety, probably the strongest growing of all and the

largest flowering. I bloomed a very fine form of this from an importation some four years ago. The sepals and petals are broad, bright rose, with deeper veins and pencillings. The lip is large and spreading, yellow in the throat with a deep crimson blotch on the front lobe. All the varieties are natives of Santa Caterina, in Brazil. H.

### BURLINGTONIAS.

WHILE some despise the smaller-flowering Orchids such as are contained in this genus, others admire them, and certainly where anything approaching a representative collection is aimed at they ought to be included. It is only a small genus, comprising about seven or eight distinct species, these being rather small-growing pseudo-bulbous epiphytes. They may be grown in either the East India or Cattleya house and are most satisfactory in shallow suspended baskets. The flower-spikes are produced at various times from the base of the pseudo-bulbs and bear a number of small flowers, the sepals and petals usually rather insignificant, the lip being the most showy part of the flower. The roots are not large, but very plentifully produced when the plants are healthy, and they like a very open compost consisting largely of Sphagnum Moss and charcoal, which is apt to get too close if used in a greater proportion than one to three of Moss. About an inch of this material is sufficient for medium-sized plants, using a little more for large specimens or made-up baskets. It is in the atmospheric treatment that growers usually go wrong with Burlingtonias, these small-growing Orchids not being able to withstand fluctuations of moisture so well as grosser growing and feeding species. When the atmospheric conditions are right many of the Burlingtonias push out their roots over the top of the compost, and these serve the purpose of auxiliary conductors of moisture to the plants, and are possibly as important as those in the compost below. They do not like disturbance at the roots, and in basketing the plants, especial care should be taken with the drainage, thus obviating the necessity of frequent repotting. All the species are very subject to the attacks of white scale, this being most difficult to eradicate. The plants must be frequently sponged, and even then probably some will remain at the bases of the leaves and among the roots at the junction with the pseudo-bulbs. Cleaning must, however, be persevered with, or but ill-success will be the result, as no plant can make a free growth with the continual drain upon its resources that the presence of insects entails. A deal of attention is needed in watering during the time the plants are in active growth, a good washing from the syringe being very helpful on bright days. Burlingtonias like a clear light and only need shading when the sun is very bright, the foliage being thicker and more solid than on some larger-growing plants. While at rest they must not be allowed to remain dry at the root long, as the pseudo-bulbs soon waste under this treatment, which is not necessary to induce them to flower. I have seen Burlingtonias well grown on blocks with Sphagnum alone, but a good deal more attention is required if grown in this way. The species most generally grown are—

**B. CANDIDA**, a very graceful and pretty plant when in blossom. The racemes are pendulous, bearing from three to six or more beautifully marked flowers, each about 1½ inches across, pure white, excepting a yellow stain on the lip. This is usually the first to bloom, being generally in full beauty in May, and the flowers last about three weeks in perfection. It was introduced from Demerara in 1834.

**B. DECORA** is the most difficult to keep in health, as its staggling habit of growth makes

it necessary to peg the pseudo-bulbs down to the compost frequently. If this is not attended to they get weaker every season and soon have a very untidy appearance. This produces longer racemes than the last species, the sepals and petals being very pale rose, the lip pure white. This is very inconstant in its time of flowering, but is now at its best in some places. A larger-growing, brighter-coloured form is *B. decora picta*. The typical plant was introduced in 1852 from Brazil.

**B. FRAGRANS**, as its name implies, has scented flowers, but their fragrance is not liked by everyone. It is a compact-growing, free-flowering plant, introduced from Brazil in 1850. The blossoms are pure white, excepting a stain of yellow on the lip. GROWER.

### MASDEVALLIA HARRYANA.

THIS is one of the best, if not the best, of the showy-flowered Masdevallias, deservedly popular and everywhere admired. Good plants of this species with a dozen or more flowers are most beautiful objects in the cool house, and form a striking contrast to the quieter tints of the other occupants. The cultural requisites of this kind are similar in all of this section, as represented by *M. Lindeni* and *M. Veitchi*. It enjoys a cool, moist, and well-ventilated atmosphere all through the year, and it requires very careful watering, the roots being easily injured by over-abundant moisture. On the other hand, it must not be dried, or the plants will be so weakened that they will probably not produce many flowers. The great point is to keep a sweet and sound root-run, and, if necessary to do so, the plants are better repotted annually than to allow the compost to get into a sour or waterlogged state. *M. Harryana* is a free-rooting species in this description of compost, and if the roots are kept intact and healthy, the plants are sure to do well. Cleanliness is of the utmost importance; the pots should be frequently scrubbed and the foliage kept quite free from insects. The chief enemies are scale and yellow thrips, the latter almost invariably making its appearance just before flowering time. Where a fairly large number of plants is grown it is best to lightly fumigate them twice on successive evenings after sundown, choosing a calm evening for the operation. This should be done before the flowers show colour. If this is neglected and the thrips are allowed to run over the plants, the majority of the flowers will be ruined in appearance by the white marks left by these active little pests. There are several proprietary articles now advertised for fumigating that are much more effectual in their operation than tobacco paper and safer in application. Should green-fly make its appearance, this may be easily got rid of by dipping the plants in a solution of soft soap and tobacco water, syringing them afterwards with clear soft water. For scale, sponging will be necessary, and this must be very carefully done, as the leaves are brittle and easily snapped off at the bottom, often bringing away with them incipient flower-spikes. All through the summer, the plants, of course, must be heavily shaded, but in winter a clear light is of great importance, and the plants should be brought up as near the glass as possible. The temperature ought never to go below 45°, and if 5° higher it is all the better, as the species can never be said to be quite at rest. The plants are usually safest in rather small pots, as the larger the specimen, and consequently the more peat and Moss used about the roots, the greater the danger in winter. Large specimens may easily be made up at flowering time by selecting a suitable number of small plants, grouping these in pans and surfacing with Sphagnum to hide the rims of the pots. *M. Harryana* is a very variable species, the type bearing flowers 3 inches in diameter, bright magenta-crimson, with a yellow tube and throat. *Splendens*, *regalis*, and *atro-sanguinea* are among the best varieties I have seen, and all are natives of New Grenada, whence the type was introduced in 1869. R.

## KITCHEN GARDEN.

### WAITING FOR RAIN.

THERE has been much important work deferred this season in the hope that a change from bright, dry, hot weather to a rainy time, but which never came, might take place. In some few districts rain fell in appreciable quantities, or sufficient to admit of seed sowing and planting being carried out under somewhat favourable conditions, but in the majority of cases waiting proved of no avail. Those who missed putting out Brussels Sprouts, Borecole, and such like just when the plants were fit have since had to do this work under worse conditions than prevailed a few weeks earlier, as their plants were drawn and leggy and the ground hotter and drier than is often the case even in July or August. Old hands seldom make such mistakes. When plants in seed beds or which are pricked out receive a thorough soaking of water at the roots, they soon after transplant readily enough, and only those of the latter, moved without a ball of soil about the roots, flag badly for any length of time. I put out Brussels Sprouts, Borecole, Cauliflowers, and early Broccoli directly after early Potatoes were moulded up, and about three waterings since have been sufficient to give them a good start. They will not be overtaken by any plants put out a month or so later. It is much the same with Celery. If the trenches were got out, as they should be where possible, several weeks before they are required for the plants, there need be no great difficulty in getting them into a suitable condition for planting. Should the soil disposed over the manure be rough and hard baked, give enough water to soak the clods, and all will then break down readily enough. On no account ought Celery plants pricked out in beds to remain where they are till they press against each other, as this means drawn-up leaf stalks and an inevitable severe check, moved when they may be. While yet sturdy and nearly or quite clear of each other, give the soil about them a good soaking and soon after transplant with as much soil and roots as can be saved with each. Well fix in the trenches or beds, give a good watering, and, if it can be done, shade lightly with Pea stakes. The plants will not flag much even if no shading is given, but they ought to be given an overhead watering in the evening of every hot day and an occasional soaking at the roots thenceforward. More Celery has been spoilt by those responsible waiting for rain before attending to the planting than from any other cause. It should also be remembered that rain when it does fall must be very heavy indeed if it is sufficient to well moisten the soil about the roots of Celery in trenches. More often than not Celery suffers from an insufficiency of water at the roots during a showery season than it does in very dry weather. It is astonishing how rapidly the plants exhaust the moisture in a trench, and it is the condition of the soil well below the surface that ought to decide the point as to when to water, and not the surface. Waiting for rain is a risky proceeding in the case of plants newly put out, but after they are once well established watering may cease with advantage unless thorough soakings can be given. The value of a good mulching of strawy manure, Grass from the mowing machine and such like cannot be over-estimated this season, these when timely applied doing far more good than dribbles or even drenchings, more especially of cold well or spring water. Where the ground is very poor the crops are

failing badly this season, no matter how often water is given, this showing how necessary it is that they be given something stronger than water to live upon.

Waiting for rain is equally unwise in the case of seed-sowing and thinning of crops. It is true much seed has been sown that has not as yet shown signs of germinating, and many seedlings have come up only to be destroyed by insects before they have formed rough leaves. Where large breadths of land or whole fields had to be sown with Mangold and Turnips, those who were late in doing this have, apparently, little likelihood of being compensated for their pains, but gardeners have a better chance of combating against excessive heat and dryness. They, as a rule, ought to be able to get their ground into a finer free-working state, and, thanks to spade labour, their ground is not nearly so quickly exhausted of moisture as is the case with ploughed land. In addition to this they are in a position to well moisten the drills previously to sowing the seed, and when thus treated germination takes place far more quickly and surely than when the seed is sown in dry drills, covered with soil and then watered. The dry weather ought not to deter anyone from sowing salad-ing, notably Lettuces, regularly, or say every fortnight, thinning out and leaving the plants where they are to grow, thereby avoiding transplanting; but, on the contrary, is a very good reason why this practice should be persevered with. More Carrot seed (giving the preference to Horn varieties) ought also to be sown, the aim being to keep up a good supply of tender young roots throughout the autumn and early winter months, and there should be no further delay in the matter of sowing seed of small, quick-growing Cabbages or Coleworts for planting thickly, as these are most acceptable in the autumn and winter. There certainly ought to be no waiting for rain in the case of such an important crop as spring Cabbage. Seed of reliable varieties—Ellam's Early Spring and the true Wheeler's Imperial—should be sown during the second or, at the latest, third week in July, a successional sowing being made a fortnight or three weeks later. It is true the Turnip fly is very troublesome in dry, hot weather, young Cabbage seedlings sometimes suffering badly from its attacks, but an occasional watering with only moderately strong liquid manure will hasten growth and check the ravages of the fly. This is the best remedy I have yet tried, and it answers well in the case of Turnips this season. A showery time is sometimes waited for in the case of sowing for the principal crop of Turnips, but we may easily err in waiting too long, especially when that excellent hardy variety Chirk Castle Black Stone is grown. In the colder districts winter Turnips ought to be sown in close succession to early Potatoes, but in the more favoured southern localities they may well follow second early Potatoes, levelling, breaking down the ground, opening the drills, watering these, and then sowing the seed, no matter how dry and hot the weather may be. When the weather happens to be very hot and dry in July and August, sowing of winter Spinach is often deferred till it is too late in the season for the plants to attain to a serviceable size before severe frosts intervene. The ground ought to be early selected and prepared for this very important crop, plenty of sunshine and air greatly benefiting it, while should a soaking rain fall before the time has arrived for making the first sowing, the opportunity ought to be taken of breaking down lumpy ground with rakes, this keeping in the moisture and admitting of seed sowing being done when the proper time arrives without much further

trouble. Should the ground be very dry about the second week in August, seed must yet be sown then, using the watering pot for moistening the drills.

Very many Onions have been spoilt owing to those responsible waiting too long for rain before thinning. This was a mistake, even if rain had fallen when most anxiously expected, as quite small Onions, as well as Carrots, Parsnips, and Turnips draw readily enough, no matter how hard the ground may be, and early thinning would have made it better in every way for those that were reserved. Runner and Kidney Beans came up very regularly and strongly, and ought to have been freely thinned in very many more cases than was done. If rain falls heavily before these notes appear it will yet be too late to thin out, as the plants have already twined round each other and will continue to smother and rob one another as long as they live.

A ROVER.

**Celeriac.**—This must now receive attention both in the matter of drawing out any suckers that may form at the base and thoroughly drenching with liquid manure. Scarcity of root moisture induces a tough, bitter-flavoured stick, more so even than in Celery. The Celery fly is likely to attack the foliage, and must be removed by hand-picking, all insecticides proving useless. If any late sowings are yet unplanted, no time should be lost in getting the young plants out, giving a good rich larder and watering frequently after the removal. A good mulch on either side of the rows where planted singly will be of much help in preserving the moisture until the plants are established, when manure water must be given as recommended for the earlier plantings. After planting, shade from hot sun with evergreen boughs. Some may deem this waste of time, but I find from experience that crops so shaded at midsummer make quicker and better progress generally than these which have to take their chance. Be sure to soak the bed well the day before removing the plants.—C.

**The Onion maggot.**—During hot, dry seasons spring-sown Onions invariably suffer more from the attacks of the dreaded maggot than when a maximum amount of rain falls; consequently a sharper look out is needed and more frequent dressings of soot given. One of the best ways of applying soot is by soaking the ground over night with clear water and sowing it broadcast the following morning, again watering liberally. As is well known, soot, as well as being a powerful insecticide, is also a good manure for the Onion crops. Beds of Onions sown late for producing bulbs for pickling may now be thinned, but only moderately, as the smaller the bulbs the better. The same precaution is needed in keeping off the maggot as with the main crop. The Queen is a capital variety for sowing for pickling, being very mild, and the colour a beautiful white. Shallots must also now have another good drenching with liquid manure; this will carry the crops on to maturity.—N.

**Value of deep cultivation.**—Never were the remarks of "H. C. P." (p. 437) better exemplified than in a field of Potatoes close to where I write. The instance here quoted is a field of Potatoes under what I will term farm culture. The land was a two-year Clover ley. The first week in April of this year it was ploughed and the Potatoes dropped into the furrows as the ploughing went on. A small quantity of artificial manure—kaimit, I think—was scattered along the rows with the Potatoes. The land being wet at the time, and heavy naturally, the bailiff considered he would be keeping the moisture in the soil by so managing it (?). The result is the Potatoes took an enormous long time to push through the soil owing to its hardened state; in fact, many never came up. The growth since has been, as might be expected, exceptionally slow. Indeed, it would be difficult to find a worse looking Potato crop

anywhere. In land of this character Potatoes do not require much rain; in fact, when it is deeply cultivated little is required until the Potatoes are forming at the base. I never saw Potatoes in the garden here looking better than at the present time, in spite of the fact that one-eleventh of an inch of rainfall has been recorded here since April 26.—E. M.

**November Cabbage.**—In some gardens it is a common practice to sow at the present time seed of some of the small quickly-heating Cabbages for a supply during November, and such is a capital plan, as they prove most useful just at that particular period before the Coleworts are at their best. A little frost improves the flavour of these November Cabbages, and they are as a rule much appreciated in the dining-room. To be successful, however, with this batch, good rich, cool ground must be selected for sowing the seed, a quick growth being indispensable for keeping at bay insect pests during the autumn months. Thin out the seedlings as soon as fit to handle and prick out the permanent plants on to a convenient plot where their wants can be attended to. Allow them to remain here till of good size; then take up carefully with a trowel when in a thoroughly moist state and plant on good land, watering once or twice with liquid manure. Two of the very best Cabbages for the purpose are Wheeler's Imperial and Cececa-nut. Where Cabbage quarters have been cut over, and it is intended to leave the old plants for supplying useful sprouts in winter, those that form now and for some time to come must be removed in quite a small state, to reserve vitality for a later date. Any that have run to seed should at once be pulled up and thrown away, as all side sprouts issuing from them are sure to run to seed also.—C. N.

**Field Potatoes.**—In many districts these were badly injured by frost on the night of June 16. Being thus weakened, all possible care should be taken to give them any chance of outgrowing it and of bulbing in satisfactorily. Earthing up must not be postponed until the haulm has grown considerably, or the plough or hoe will do much damage amongst the extended rootlets. If favoured with showers a good surfacing of some quick-acting manure will help them greatly just at this time, another being given as soon as the tubers are as large as Walnuts.—J. C.

#### TOMATOES NOT SETTING.

I HAVE a cool house for growing Tomatoes and I cannot understand why the Tomatoes do not set, they have bloomed well and have had plenty of air. I have planted several of the same kind outside and these are doing well.—J. H. BURT.

\* \* There are several causes of non-setting in Tomatoes, but those requiring advice upon the matter should always give fuller particulars as regards varieties grown and method of treatment. J. H. Burt merely states that he has a cool house for growing Tomatoes in, that he has also planted some outside, these latter doing well. From the fact of his having a house specially for growing Tomatoes I should say the plants are not unduly shaded by anything growing overhead, but want of abundance of sunshine and light may yet be the cause of failing to set. When the plants smother each other the flowers open feebly and are very deficient in pollen and either drop off wholesale or fail to set. The heaviest crops as a rule are set on those plants trained thinly up the roofs of houses, and at this time of year there is no necessity to tap these smartly towards mid-day, the pollen effecting a perfect set without this aid. At the same time, if J. H. Burt has not tried this plan I should advise him to commence now. Either tap the bunches of flowers with a hazel twig or else the stems of the plants generally with a stick padded with cotton wool. If the flowers are not sufficiently exposed to the light, partially shorten the leaves the better to admit more sunshine. Greenness of plants is also a frequent cause of failure to set well, and if J. H. Burt's are extra rank growing, reducing the

leaves to about half their original size will tend to check this, giving less water than previously helping in the same direction. It does good to allow very sappy plants to flag from want of water occasionally. Some varieties, Early Ruby in particular, usually set such very heavy lower clusters of fruit that this weakens the growth considerably, and the later formed flowers fail to set in these cases. The remedy would be more liberal root treatment. It may be the variety cultivated is at fault. With me Hackwood Park set very badly this season alongside other varieties that have done remarkably well. Amateurs would do well to cultivate Ham Green Favourite or varieties of that type, including Al and Challenger, leaving it to others to experiment with the more doubtful setters. It should also be added that diseased plants fail to set good crops, and there are some mild forms of diseases that are only observable in the effect they have upon the growth of the plant. Applications of disease remedies, whether these be at the roots or to the top growth, invariably check setting for a time.—W. I.

### EARLY PEAS.

Owing to such a severe winter many Peas that were sown in the open ground in the autumn perished through the long spell of frost, and those which survived were so eaten by the slugs during the showery weather in April, that many failed to grow, thus causing many blanks. Those who sowed in pots with a view to planting out will have found such sowings most serviceable, and there will be little cause for complaint, as the plants are both strong and well-podded. I have long since discarded the round-seeded varieties, and only grow such as are well-flavoured, selecting, as far as possible, the most productive. This season about a dozen of the early wrinkled varieties were tried, and amongst the best of the tall ones was Exonian. Though the pods are small they are well filled, and the plants continue bearing for a considerable time. Gradus came next, and was ready for use early in June, and this was followed by the Duke of York. Peas have not grown to the same height with me this season as they did last, for we have only had four-tenths of an inch of rain since April. Amongst the dwarf kinds Chelsea Gem still holds its own, the pods being produced in such abundance, and though not large are well filled; the flavour also is very good. I tried several kinds of more recent introduction, and amongst these I may mention Sutton's Seedling. The haulm, about 2 feet high, is of a pale green colour, well clothed with pods of medium size that are well filled with Peas excellent in flavour. This variety when it becomes known will doubtless be much sought after as an early kind on account of its dwarf habit, it being well adapted either for frames or narrow borders. Ready with me on June 15. This may not be considered early by some, but when we take into consideration the lateness of the season before the Peas were able to grow, it is certainly an advance on a great number of kinds that were sown on the same date. Sutton's Favourite is also another grand new variety. The haulm reached 3 feet in height, and was well clothed with pods to near the ground; both foliage and Peas are rather light in colour, but the flavour is all that can be desired. Daisy also had another trial, but was not so early as either of the forenamed. Sutton's Early Marrow is still well worthy of a place where good Peas are appreciated. It is an abundant bearer, pods large and well filled with Peas of a deep green hue. Peerless sowed at the same time grew to the height of 3 feet; both foliage and pods are dark, the latter being from 4 inches to 4½ inches in length, slightly curved and well filled with Peas of most excel-

lent flavour. As a second early or main crop this will prove a good kind; ready for use June 21. Conqueror grows to the height of about 4 feet; the pods are borne in pairs and are either straight or slightly turned inwards, a peculiarity of this variety; they are deep green in colour and well filled with Peas of most excellent flavour. To have vegetables of any kind in perfection it is necessary that they be well grown, otherwise they will lack that freshness so essential to please the cultivated palate. Peas should not only be grown in well cultivated ground, but should be gathered as soon as ready for use. If gathered in the cool of the morning while the dew is on the pods and taken to a cold cellar till wanted for use they will be far more tender than when gathered in the heat of the day when all the juice is extracted from them by the sun, particularly in hot dry weather when the ground is parched. If not wanted for use when ready, better gather and take to a cool cellar in the early morning than allow them to remain on the haulm till they get old and tough.

H. C. P.

### DEFOLIATING TOMATOES.

ONE of the ideas gained from a visit to the Channel Islands is that Tomatoes generally should be defoliated, and not a few amateurs and others have come away with the impression they have gained very important knowledge. As a consequence, defoliation has been carried out in a most reckless fashion and under a variety of circumstances to the no small detriment of the plants operated upon. This season I have already seen scores (I might say hundreds) of plants completely denuded of their foliage right up to the first cluster of fruit, and even the primary leaves, or those on the main stems, were freely shortened, so that the plants looked like mere skeletons. They reminded me of a large number of plants being grown under glass in a famous fruit-growing establishment in the west of England that unfortunately had been overrun by *Cladysporium* soon after this much-to-be-dreaded disease first showed itself in this country, on these being nothing but fruit and quite young leaves. In this instance the crop failed to swell to a good size or to ripen properly, and if we remove the greater portion of the healthy, fully-developed leaves from plants only just commencing to swell off their crops, we are almost certain to so paralyse their root action and to cut off supplies of sap that the fruit will be neither large, solid, nor good in quality. How can it be otherwise? The Channel Island Tomatoes are not famous for their good quality, and if the growers defoliate half so severely as do their imitators on this side of the water, the wonder is that they can make fruit-growing pay at all. Not a few of those growers are quite new to the work, and doubtless imitate one another to the best of their ability, but if we cannot do better than follow in their footsteps, gardening has fallen to a very low ebb indeed. In all probability, however, very few of them commence wholly removing the lower old leaves soon after cropping commences, nor do they follow up the practice of shortening the leaves so very closely at first. Tomato leaves are so formed as to admit of their being either lightly or somewhat severely reduced in size, and only when the foliage unduly smothers the fruit ought it to be very severely shortened. Under glass there has been and still is a tendency towards close planting. It is a mistake I have made; it is a mistake nearly every grower on a large scale has made; it is a mistake too many beginners will make; and nothing but an experience of the ill effects of close planting will bring about a more rational practice. When, therefore, the rows of plants are less than 3 feet apart, 12 inches or less apart in the rows, and ranging from 4 feet to 10 feet in height, they simply smother and ruin each other. It is then when a certain amount of foliage shortening must take place, or otherwise little or no sunshine will reach the fruit, and without this aid it will be

hollow, poor in quality, and, worst of all from a market grower's point of view, light in weight. Going to the extreme of making a wholesale removal of leaves has much the same effect. When plants are given good room and otherwise liberally treated, they grow rather strongly in spite of the heavy crops the majority of them produce, and seeing that no good cultivator allows any superfluous side shoots to form, the excess vigour communicates itself to the leaves, these attaining great dimensions. Even in this case I do not favour the practice of severely shortening the leaves, removing, it may be, two-thirds of each, but consider the case well met by the removal of a third to one-half of each large leaf, doing this at twice rather than giving a single severe check.

Open-air plants are great sufferers from this idea that defoliating is the right thing. There may be some excuse found for novices who have already cut away the lower leaves and shortened the rest, but gardeners ought to know better. By all means keep side or superfluous shoots closely snipped out, but do not weaken the plants by taking away that portion of them that has to finish the work begun by the roots. Nor do I believe in a wholesale removal of leaves after a heavy crop of fruit has been formed, but not ripened. Diseases that affect the stems and leaves are also equally at home on or in the fruit, and if we severely shorten or wholly remove the primary leaves, we take away what has hitherto afforded a certain amount of protection to the fruit. Be content, therefore, to practise shortening of the leaves, and not resort to wholesale defoliation. Trimming off all or the greater portion of the leaves is about as sensible a proceeding as drying off Melons. The best Melons are cut from plants well furnished with healthy foliage, and the heaviest crops of richly flavoured Tomatoes are had from plants also well furnished with healthy leaves.

W. IGGULDEN.

### Asparagus Late Purple Argenteuil.—

This is a capital variety and especially useful where a prolonged supply is needed. It merits the title "late," not from its being behind other varieties in commencing to produce its grass, but from its habit of continuing to produce it after such sorts as Giant Battersea, Conover's Colossal and Reading Giant have ceased. When well treated it produces extra large heads having a beautiful delicate purple tip—hence its name, Purple Argenteuil. Anyone purposing increasing his stock of Asparagus next year would do well to give this variety a trial.—J. C.

**Transplanting Celery.**—Important as it is to have good stocky, healthy plants of this vegetable, good results cannot be expected unless pains are taken at the time of removal into the trenches. The great drawback in so many instances is lifting the plants when in a semi-dry state. When this is done many of the best roots snap off and are left in the frame, while the rest suffer very quickly if exposed for a short time to sun and wind. Such plants also when planted never go away freely and often lose their lower leaves. Then, again, the trench itself is often insufficiently moist, and often watering is done in a half-hearted manner. Under these conditions there can be little wonder at so much Celery bolting away to seed. The chief point to be observed previous to removal to the trenches is a thorough moistening of the soil of the bed in which the young plants are growing. This should be done the day before, the trenches being treated in the same way. Planting completed, a final watering home should be given, and if in a very exposed situation, a few evergreen boughs fixed in the soil on one side of the trench and overhanging it will afford grateful shade until growth is resumed. In watering, mere dribbles are of very little use, these often leaving the bottom roots untouched. Occasional thorough drenchings are what are wanted, the plants then standing some time without being distressed. Celery, if healthy and sufficiently moist at the roots, will stand, and in fact enjoy, any amount of sun with impunity.—J.

## ORCHARD AND FRUIT GARDEN.

## EMPEROR ALEXANDER APPLE.

This is one of the handsomest Apples in cultivation when well grown, and a great favourite with exhibitors, as its large size, good shape, and lovely colour make it a telling dish in a collection. In the back row of a collection its rich red colour is very striking if staged between two dishes of a green or golden colour, and many visitors to our leading shows make a careful note of the name with a view to ordering trees of the variety when the planting season arrives. When these trees are plucked for private use only, no harm is done, as the variety crops fairly well on good soil, but when required for market the result is somewhat disappointing, as the variety is not so productive

all varieties, and although the above kind, as stated, is supposed to only bear every second year, it crops regularly in the orchard mentioned. When grown in bush form, close or severe pruning ought to be avoided, as a mass of wood is made with little or no fruit, but by disbudding or thinning out the shoots in the growing season, so that each one left gets plenty of light, and allowing it to remain nearly full length at the final pruning, fair crops of large highly-coloured fruit will be produced most years, unless climatic influences are against the same.

W. G. C.

**Fig Osborn's Prolific.**—Mr. Wallis, of Keele Hall, Stafford, had in his collection of fruit at the York show a magnificent dish of Osborn's Prolific Fig. On finding that I did not grow it, he said, "You certainly ought to do, as it is a capital cropper and of very good flavour." The fruits in

*Apple Emperor Alexander. From a photograph sent by Mr. Norman Blake, Bedford.*

as many other cooking sorts, and when there is a crop, and it must be consigned some distance to market, it is found that the Apples are so soft that they travel badly; consequently, owing to the bruised condition of the fruit, it realises a low figure, and every day that the Apples are kept after reaching the market the bruises become more pronounced. In some parts of the west of England there are many trees of Emperor Alexander Apple grown, chiefly in standard form. These trees, as a rule, bear a moderate crop every alternate year, but, as previously mentioned in THE GARDEN, there is no reason why such crops should not become more frequent, as it is simply a question of feeding. In one of our orchards in which sheep are fed with rich food to get them into condition for show and selling purposes; we find a marked difference in the annual crops and the size of the fruit of

question were large, of a somewhat greenish cast, and in shape somewhat like well-grown fruit of Negro Largo. Some of the earlier forcing Figs, which have been introduced since the old Brown Turkey, are rather small in size. Osborn's, however, by all accounts is the reverse, as well as being (as its name implies) prolific.—J. C.

**The Gooseberry caterpillar.**—There are few gardens which are not annually troubled in a greater or less degree with this terrible pest. Its ravages not only affect the present year's crop, but are the forerunner of puny wood and buds in the future. Many so-called remedies are recommended, many of which are positively dangerous, the insecticides themselves being of a poisonous nature. My plan, and which has proved effectual year after year, is to thoroughly well dust the lower portions of the bushes with soot and lime, doing it in an upward direction, and, of course, directly the pest is noticed. Use the soot and lime in equal proportions; this fetches all the

caterpillars down to the ground, when a second dusting can be given them, which proves fatal. This stops any further progress, and the few fruits which unavoidably become covered with the mixture are easily washed before being used. Any one troubled with the Gooseberry caterpillar will find this a safe and efficient remedy if carried out in earnest on the first appearance of the pest. I certainly have a great antipathy to any poisonous mixtures being used on anything that has to be eaten afterwards.—J. CRAWFORD.

## POT CULTURE OF MELONS.

ALTHOUGH growing and fruiting Melons in pots is by no means a new practice, it is one which does not receive the attention it deserves. Pot culture, although profitable at all times, is doubly so early in the year for the first crops, and those who have proved its value will not readily abandon it. Some favourite varieties also which are prone to make strong growth do not always set their fruit so freely as is desirable when planted out and allowed a bed of leaves to root into, especially in a dull sunless spring, when growth is often rampant and bloom scarce. The best lot of Melons in pots I ever saw was in a Kentish garden, the variety being Heckfield Hybrid, still one of the best of its class. The pots, 12 inches in diameter, were plunged in a narrow bed of oak leaves beneath which was a chamber for hot water pipes, and although the spring was not one of the best, and the temperature of the house lower at times than was desirable, the plants ripened off a splendid lot of fruit, large and of capital flavour, each plant carrying from three to four fruit. Since then I have always grown a portion of my crop in pots. It may be thought that the limited body of soil a 12-inch pot can contain is insufficient for the roots of a vigorous Melon plant, but if firm ramming is resorted to when the final shift is given, and judicious mulching and feeding when once the fruits are set, the plant will carry and mature four or even more fruits. If I want the fruit to ripen extra early, I place the pot on a piece of slate when plunging, and by screwing it round occasionally prevent any roots from penetrating the bed of leaves beneath. This of course hastens maturity. Melons when grown in pots always make a harder and more wiry growth than when planted out, and the fruit can often be secured on the first laterals from which it more often than not parts, when the plants are grown in the ordinary way. I always think, too, that the flavour of pot-grown fruit is superior. In houses where bottom-heat pipes are not over-plentiful Melons often fail to set, and swell from an insufficiency of root warmth, but if the pot system is adopted more fermenting material can be rammed in round the pots just when the plants are coming into bloom, and thus an easy and free set secured. Of course, there is a good deal of labour in watering inseparable from pot culture, as Melons (like pot Strawberries), if once allowed to get dry at the roots after the fruit is set, might as well be thrown away. Twice, and in some cases three times, a day the ball must get a thorough moistening, once being with liquid manure. The smaller-sized Melons, which do not make so much growth, are admirably adapted for pot work, as they are easily supplied with all the nourishment they require; while the more robust, rampant-growing sorts (for second early crops) are by pot culture restricted and made more prolific. If fruit of the very largest size is required larger pots can be given, and I have heard of some growers using Seakale pots, these being deep, but not wide, so as to monopolise the room. I have always found canker to be less prevalent in pot-grown

plants, the hard and wiry character of the roots and growth generally, doubtless, accounting for this. Later in the season Melons may be grown very profitably in pots without the aid of a hot bed. On the kerbs of Pine stoves or similar structures where the sun can shine directly on the pots they will do well, if allowed to carry only some three fruits each and well nourished. Beauty of Syon, Gunton Orange, Hero of Lockinge, Scarlet Premier and Baron Hamilton, a grand new scarlet-fleshed variety, are all well adapted for fruiting in pots without any actual bottom-heat. J. CRAWFORD.

**Early Rivers Cherry.**—Recently when out for a day I passed a cottage with a Cherry tree on its wall so heavily cropped and the fruit so large and striking, that I went to the door and asked the occupier what variety it was and how she accounted for the fruit attaining such an extraordinary size, though the crop was so great. The answer was, "The name is Early Rivers, and the only reason I can give for the big crop and large fruit is that every time I am washing I always throw the soap-suds about the roots, and if any blight appears I send the suds over the leaves." I further learned that she could always sell all the fruit in either plentiful or scarce seasons at sixpence per lb., the demand always exceeding the supply, people coming to fetch the Cherries from the house. Several lessons may be learnt from this old woman's experience. First, that even in country districts miles away from a town or good market cottagers can realise a high figure for produce of more than ordinary merit; in fact, such produce practically sells itself. Secondly, the immense value or importance of a plentiful supply of plant food to fruit-bearing trees. I cannot say what the manurial elements are in soap-suds, but no doubt potash predominates, and the quantity applied by the means of a weekly or perhaps fortnightly soaking all the year round must amount to a very considerable total in twelve months. It was very evident there had been no excess, as the fruit, wood and foliage were as good as they possibly could be. Thirdly, the benefit of having the walls of houses or other buildings covered with fruit trees of profitable kinds instead of permitting them to remain bare, ugly, and unprofitable was evident.—R. H.

**Notes on Currants.**—Probably Black Currants will be of more than ordinary value this year, as complaints are becoming common about the fruit dropping to a serious extent. One large grower writes me this morning (June 25) that he is losing half his crop through the drought. Through keeping the surface soil loose very few berries have fallen with me and the crop is fully up to the average. Ogden's and Lee's Prolific are bearing the heaviest crops, the fruit being large, firm, and of deep colour, and both varieties are excellent for home use or market. Red Currants are a very heavy crop, all sorts being well laden with fruit. Raby Castle is a well-known good variety, but decidedly inferior to La Conde, and no doubt, as this gets more widely known Raby Castle will be superseded by it. The growth of La Conde is strong and well furnished with large clusters of berries, fine in size and colour. The old Red Dutch and Grape varieties are also remarkable for their prolific habit and general excellence. It must be a vile season for any of the above to fail, each variety being vigorous and producing foliage early that protects the fruit in the embryo stage from frost. Reine Victoria is the latest variety that I have had any experience with, and it will hang in a perfect condition for a long period after ripening if protected from wet and birds. Amongst White Currants the new variety named Champion promises to be an acquisition, the bunches and fruit being much superior to those of any sort that I have, also producing the same freely. White Dutch is a well-proved old favourite, and is perhaps more universally grown than any of the whites, but, with all its popularity, I think Champion will take its place in the

future. It would be a mistake for intending growers for market to plant White Currants on an extensive scale, as the demand is very limited. Sometimes one may dispose of a few hundred-weights at satisfactory prices, and again it happens that they will scarcely sell at any price. If there is a good market annually for White Currants I have yet to discover where it is.—W. G. C.

**Strawberry Royal Sovereign.**—I do not wonder that Mr. Salter is much in favour of this Strawberry for forcing, seeing that it is such a grand variety in every way. Perhaps it will not prove to be so valuable as some other kinds for early forcing, but for ripening its fruit in May it is doubtful if any other can rival it. From plants in 6-inch pots I gathered at the end of May fruit each weighing  $1\frac{1}{2}$  ozs. It is also an excellent sort for growing in the open. Upon one plant put out last year after being forced I counted to-day fifty-five fruits, not taking into account the small ones. Several of these weighed  $1\frac{1}{4}$  ozs. The colour is bright and taking in appearance. The flesh is firm and of pretty good flavour. It is a Strawberry that carries plenty of foliage, thus enabling the fruit to swell to a large size. When better known I am sure it will be much grown. It ripens early out of doors. My first fruits of it were gathered on June 11 from a west border—by no means an early position.—E. M.

#### GOOD EARLY NECTARINES.

I do not quite agree with "W. G. C." (p. 395) as to the terms used for the new Nectarines Early Rivers and Cardinal. I fear he was so much impressed with the small fruits on a small tree in a pot placed by the side of a basket of Cardinal (the last new one) that he at once came to the conclusion it was so superior. Our old friend and favourite, Lord Napier, was staged in such a condition, that it cut a sorry figure by the side of the newer Cardinal. Now it is scarcely fair to stage a Nectarine such as Lord Napier beside the newer Cardinal in such a small state. There is not the least difficulty in having ripe fruits of Lord Napier in May; in fact, first-class fruits have been staged several times at the Temple show. Last year good fruits of Lord Napier were staged equal to those of Early Rivers in quality, colour and size. If the Lord Napier, as was stated, had been given the same treatment as the Cardinal staged, the difference would not have been so marked as in the fruits exhibited. I have made inquiries of noted growers; some say Early Rivers is a few days earlier, but not to the extent of the fruits of one being ripe when the others are not half-grown. In this case it was Cardinal that was staged by the side of Lord Napier, not Early Rivers, but the same test was applied to Early Rivers last year or two years ago. Everyone now knows that Early Rivers forced is not a month or six weeks in advance of Lord Napier. We have not got to that perfection yet of having Nectarines so much earlier. Cardinal I have not tried; it may be as early as was stated, but our old favourite, Lord Napier, should not be shown in a small state—little larger than Cob Nuts on May 21, as there is no difficulty in having ripe fruit at that date. Cardinal must have been forced to be ripe, as it is out of the question without forcing to have ripe Nectarines, however precocious, at the date named. "W. G. C." tells us that new early varieties do not drop their buds. I have had no experience of bud-casting in these fruits, so was not prepared to find that a recommendation. Others may; I never have in the course of long experience at Peach and Nectarine forcing. Peaches are sometimes troublesome, but with me Nectarines are exempt. Cardinal, he also states, is equal to Early Rivers in every respect, but why was there no an-

nouncement as to its being sent out? I have heard that it is not recommended as an outdoor Nectarine, as it does not do well in the open, whereas Early Rivers does. I have no interest whatever in either of the fruits, only having grown one—the Early Rivers, but I do think that Lord Napier is deserving of better treatment, as it is a fine fruit indoors or out and forces readily. To get Lord Napier in May, I start it early in December, allowing nearly six months. I have yet to learn that the newer Nectarines require only about four months, but if so, it is a great gain. I have forced Lord Napier in a little more than five months, but one cannot expect long-lived trees with such treatment. It is very different to grow fruits for exhibition, and, as far as I could judge, none of the fruits were very ripe or they would not have travelled. "W. G. C." tested the flavour and described its quality, and nothing can be said against it as regards colour or appearance, but can you call a fruit good which is stated to crack badly in the open? Lord Napier does not crack, and I send this note as a plea for an old well-tried kind that has served us well.

FRUIT GROWER.

#### GARDEN FLORA.

##### PLATE 1021.

##### THE GREATER CHRISTMAS ROSE.

(WITH A COLOURED PLATE OF HELLEBORUS ALTI-FOLIUS=H. NIGER MAXIMUS.\*)

THIS noble plant, formerly portrayed by Mrs. Duffield in THE GARDEN, and also known as *H. niger maximus* in some places, is by far the boldest and most robust of all the Christmas Roses at present in cultivation. The finest flowers of this form I ever saw were sent to me from Newton Abbot, in Devon, by Mr. T. H. Archer-Hind some years ago, each bloom being 5 inches in diameter and nearly pure white in colour, though, as a rule, there is some rosy purple colouration in its flowers. *H. altifolius* is, I believe, as above indicated, the very best of all the Christmas Roses for rough-and-tumble culture in all soils and situations. After it I should place the Riverston variety, as distributed from Mr. John Poë's garden at Riverston, Nenagh, some few years ago. As a dainty queen of Christmas Roses St. Brigid's variety is exquisite, perfect in its pale green foliage and purest of white flowers, but, alas! like other beautiful things, it is a little capricious, and does not do equally well in all soils and situations, but as seen at its best it is one of the very finest kinds. The Manchester var. called *H. niger angustifolius*, not the true *H. niger angustifolius* of McNab and the late Miss Hope, of Wardie Lodge, Edinburgh, is also a pure white, very effective and free-flowering kind, but its leaves are more acutely serrate than in St. Brigid's form, and there are other differences very evident to the practised eyes of Mr. Walter Ware, Mr. Veitch, of Exeter, and others who grow and think much of these pearly winter blossoms. As I have said, there is generally more or less of rosy purple suffusion in the blooms of *H. altifolius*, but there is another form of it called *H. niger Apple-blossom* by Mr. Ware, a narrower-leaved form, bearing a profusion of rose-tinted flowers very suggestive of the flowers of a rosy-blossomed Crab or Apple tree, as suggested by its varietal

HELIOPSIS SCABERIFOLIA

## EDOUARD F. ANDRÉ.

M. EDOUARD F. ANDRÉ, whose name is widely known in our country as botanical traveller, horticulturist, and one of the leading landscape-architects of his time, was born at Bourges, in the department of the Cher, France, July 17, 1840. He began to study horticulture at a very early age with his father, who was a nurseryman in that town. Having completed his classical studies at a very early age, his decided taste for horticulture induced him to stay a year in the establishment of M. Leroy at Angers. Then he went to Paris in 1859, and spent another twelve months in following the course of botanical instruction and in practical training at the Museum of Natural History, under the direction of Professor Decaisne. This was the first period of Mons. Ed. André's exertions in horticulture and botany. In the year 1860 he was called by Mons. Alphand to a post under the Municipality of Paris at the time this remarkable man commenced the transformation of that city.

The appointment of Mons. André to the post of Principal Gardener to the town of Paris, which position he held during eight years, enabled him to take an active part in the laying out of the public gardens and parks of Paris, and during many years he was director of the well-known municipal establishment "Fleuriste de la Muette." Mons. André's principal part in these important works was the planting of the Park of the Buttes-Chaumont, perhaps the most picturesque public park in the world, with its high cliffs, abrupt slopes, gigantic grotto, powerful cascades, mountain scenery and natural planting. In 1866 the Corporation of Liverpool, having acquired a large piece of land from Lord Sefton, opened a competition for the laying out of a public park, and invited artists of all countries to take part in it. Two prizes were offered—one, three hundred guineas, the other, one hundred and fifty. The area of the park was 370 acres, and the competition was not only for laying out the park itself, but the arrangement of boulevards and roads and the disposition of the land around it for building. A large number competed, and among the 29 selected by the jury, Mons. André, who had adjoined to him Mr. L. Hornblower specially for the department of architecture, was unanimously awarded the first prize by the Corporation of Liverpool on April 26, 1867, and also appointed to direct the carrying out of his plans. The work lasted five years, from June, 1867, to May 20, 1872, when the park was formally opened by the Duke of Connaught (Prince Arthur).

Since that time the works executed by Mons. André can be counted by hundreds, not only in his own country, but throughout the world. Among them may be mentioned the drawings of Woodhouse-Moor Park, Leeds, the parks of Saumarez Hall and Melrose, Guernsey, Mr. Allain's in Jersey, Allerton Priory, Liverpool, Impney, near Droitwich. In Holland he planned and superintended the curious reconstruction of the grand French Louis XIV. parterres in the domain of Weldam belonging to the Count Bentinck, and also those of Amerongen, the Baron de Heeckeren's. In Denmark, the park of the Count de Friese at Friesenborg. In Russia, Otrada, Count Orloff-Davidoff's. In Austria, the parks of Prince Lichtenstein and Baron Nathaniel de Rothschild at Eisgrub, Hohe Warte, and in Vienna. In Madeira, the public gardens at Funchal. In Bulgaria, those of the residence of the reigning Prince Ferdinand. In Switzerland, M. Hübner's park at Sissach, and Vorpillière, Count Riant's, M. Micheli's at Crest, Baronne Adolphe de Rothschild's at Prégny, and M. Ern. André at Crassy. In Italy, the squares of the Piazza Bianca and the Quirinal in Rome, the plans of transformation of the great park of universal fame called "Villa Borghese," the parks and gardens of M. Hüffer at San Pancrazio near Lucca, those of the Count de Rigo at Menaggio, &c. One of the most interesting of Monsieur André's undertakings was the transformation of the Citadel of Luxembourg into a public garden. The Grand Ducal Government was compelled, in virtue of the Treaty of London in 1866, to erase the fortresses of the town,

and entrusted to Mons. André the portioning and laying out of the land into a public park, botanic garden, boulevards and squares. The work was begun in 1872, and was only completed in 1892. The park of the Hospital Pescatore was laid out by Mons. André, who also greatly changed the thermal establishment of Mendorf, and gave the plan for the reigning Grand Duke's park of Walferdange.

In 1890, the Government of Uruguay requested Mons. André to pay a prolonged visit to their country, and to prepare them plans for the remodelling a part of the ancient town of Montevideo, and planning a new city in better proportion with the rapid increase of the population and the requirements of modern taste and civilisation. This great undertaking comprised three public parks of 100 to 210 acres, ten squares, and a vast number of avenues and boulevards. These plans were sent, and the realisation of them is being gradually carried out. The beautiful gardens of Monte Carlo, laid out by Mons. André, have acquired a universal repute, not only for their elegant design, but for the numerous plants of tropical origin planted there, and which thrive admirably under the Mediterranean skies. To the same author belong the designing and laying out of the following parks: Ermenonville, Laverville, Avanges, Mégaudais, Le Lude, Les Crayères near Rheims, St. Roch, Prye, Bois-Renault, Briare, Beauvoir, Courville, Peyrieu, Melzéar, Ansemes, Iville, Pinon, Germancy, Captan, Marolles, Toussicourt, Mignaux, in France: Sentheim, Guebwiller, Lützelhausen, in Alsace, Hayange and Jœuf, in Lorraine, and many gardens on the shores of the Mediterranean. He also laid out squares of the towns of Chaumont, Cognac and Poitiers, and made capital alterations in the disposition of the thermal town of Bagnoles, creating boulevards, avenues, elegant villas, a church, race-course and a market-place.

It is natural enough to think that such works should be followed by the publication of a book detailing the artistical principles, the theory, and the practical views of the author. In 1879, Mons. André published in Paris his "Art des Jardins," a general treatise on the formation of parks and gardens, which is illustrated with eleven chromolithographs and 520 wood engravings, and has become a classic work in France and Belgium. In 1892 Mons. André was appointed by the Government Professor of Horticultural and Landscape Architecture to the National School of Horticulture, being the first time in France that official instruction in these branches of horticulture has been given *ex professo* by a specialist, which innovation has proved of much good.

The career of Mons. André has been as much that of a horticultural writer as a landscape gardener. In 1864 he published a treatise on plants which grow in peaty soil. In 1865-66-67, three volumes of reviews entitled "Horticultural Movement." In 1866 a work on ornamental foliaged plants. In 1867, "Ferns," in collaboration with Messrs. Roze and Rivière. He published an account in 1869 of a part of his travels in the East called "A Month in Russia." From 1870 to 1880 he was editor of "l'illustration Horticole," published at Ghent, and the eleven volumes of this period are almost entirely from his pen.

A large number of our readers know the results of Mons. André's travels in different parts of the world. He was sent by the French Government on a scientific expedition to South America, and he travelled in 1875 and 1876 through the richest and some of the least explored regions of New Grenada and Ecuador. He also went to the West Indies, Venezuela, Peru and to North America. Mons. André brought back with him a considerable number of new plants, both living and dried, among which a certain number are known in cultivation, such as *Anthurium Andreanum*, *Anthurium Dechardi*, *Æchmea Drakeana*, *Billbergia Breutiana*, *Billbergia vexillaria*, *Bromaria Kalbreyeri*, *Caraguata Andreana*, *Caraguata conifera*, *Caraguata cardinalis*, *Caraguata Morreniana*, *Caraguata sanguinea*, *Caraguata Van Volxemi*, *Contarea Scherffiana*, *Epidendrum arachnoglossum*, *Eupatorium serrulatum*, *Ismene Andreana*, *Loasa vulcanica*, *Philodendron Andreanum*, *Philodendron gloriosum*, *Philodendron Mamei*, *Senecio leucostachys*, *Senecio sagittifolius*, *Solanum Poortmani*, *Tillandsia Arequitæ*, *Tillandsia Lindenii tricolor*, *Tillandsia umbellata*, *Verbesina Mameana*, *Nectandra angustifolia*, *Lathyrus pubescens*, *Nemmannia arenata*, *Onoseris Drakeana*, *Podachnium andinum*, *Passiflora atomaria*, *Phyllanthus salviaefolius*, *Puya gigas*, *Sicana atropurpurea*, *Tillandsia Armada*, *Tournefortia cordifolia*, &c. Mons. André published an important account of his voyage in the *Tour du Monde* ("Round the World"), and a scholarly monograph where he described, among 143 species brought home by him, the suggestive number of ninety-one new Bromeliads which he discovered in S. America—"Bromeliaceæ Andreanæ." One portion of his botanical collection, comprising more than 4300 species, has been published under the supervision of eminent specialists, such as Passifloraceæ, Dr. Maxwell Masters; Lichens, Dr. Müller Arg.; Melastomaceæ and Cucurbitaceæ, Cogniaux; Cyperaceæ, Maury; Araliaceæ, Marchal; Piperaceæ de Candolle; Amaryllideæ, J. G. Baker; Alismaceæ and Leguminosæ, Micheli.

In 1882 Mons. André was appointed co-editor of the *Revue Horticole*, the oldest and most important of the French horticultural journals, which was founded in 1829 by Vilmorin, Poiteau, &c. For the last twelve years Mons. André with M. Carrière has been the leading spirit of this paper, which he has made artistic, practical, and scientific. In recognition of his services, in 1892 Mons. André was elected titular member of the National Agricultural Society of France (the agricultural institute of that country). He is also Chevalier de la Légion d'Honneur, Officier de la Couronne de Chêne in Holland, Chevalier de l'ordre de Léopold of Belgium, Officier de la Couronne of Italy, &c. He is as active as ever in the performance of his duties and in the development of his artistic and scientific career, and we are pleased to know that his eldest son, M. René Ed. André, is a distinguished engineer who follows faithfully his father's steps.

name. As seen at its best with the pure white St. Brigid, or with the icy cold-white of Mme. Fourcade, this Apple blossom is a most beautiful and distinct thing, and one to be grown extensively by all interested in winter flowers from the open air. Some few years ago Herr Max Leichtlin sent me a seedling of slender habit, which usually opens its first flowers in August. They are small in size, but pure white and most profusely produced. It is an ideal button-hole flower, and also the most certain seed-bearing form I know; hence it might be useful to those interested in the rearing of new Christmas Roses from hybridised seed. For growing in bulk for cutting one might do worse than plant half an acre of the true Bath major, a form largely grown by Mr. Walter Ware. It is not remarkable for size or purity of flower, but it is a splendid grower and produces a rich profusion of its snow-white flowers. St. Brigid is far finer, but does not, as I have indicated, do so well everywhere. Riverston is finer, but, alas! you cannot get 1000 Riverston just when you want to plant them, and this brings me to the kernel of these notes, viz., for planting in quantity use altifolius, Bath major, Apple-blossom, and Mme. Fourcade, and for extra choice blooms grow St. Brigid and Riverston. But we are not nearly at the end of the Hellebores of the H. niger section, since many growers are raising seedlings every year, and there are now many varieties as rare as the best Odontoglots or Cattleyas, and almost, if not quite as beautiful, and they are also for ordinary gardeners about as difficult to procure. This is one of the joys of the outdoor gardener, this rearing of choice variations from seed. Your correspondent "L. E. L.," whose "Garden Sketches" have been read and enjoyed by gardeners in both hemispheres, has a superb collection of choice seedling Hellebores, and there is a set of them in the beautiful gardens of Glasnevin that are a pleasure to see every year—flowers of all sizes and of varying form, some stellate, others as solid and as pure as the finest forms of Chysis or Cattleya, or as the Odontoglots of Colombia, and, moreover, of a purity comparable to that of the long-flowered Lilies of Japan, of Bermuda, or even of the Eucharis Lily of the South American streams.

Christmas Roses may be grown in various ways. One way, and the best way if soil and climate are genial, is to plant them out in rows, 2 feet apart or more, in sheltered spots, and they enjoy mulching with leaf-mould or manure in the spring, so as to conserve the natural moisture of the soil just as the growth begins in March or April. Heavy waterings with weak liquid manure are especially beneficial about the same time, as on a free and luxuriant leaf-growth all after-success of profuse blossoming of course depends. If the soil in which you must perforce plant your Christmas Roses is dry and sandy or gravelly, or if you are on limestone, then the chances are that a half-shady spot will suit these plants best. If, however, you have a deep, rich soil full of moisture and humus, then a sunny position will, in all probability, be the most beneficial to them. Another way, and a convenient one, is to grow these plants in tubs, large or small as the case may be, planted in good loam and peat and watered occasionally with weak soot and cow manure. The growth and flowering are very fine, and one has the element of portability, for it is often a convenience to move the tubs of Helleborus niger into the cool greenhouse after the Chrysanthemums are over and gone. The difficult time for choice cut flowers in most gardens is from New Year's Day until Good Friday, and

this is a gap filled up for the most part by Christmas Roses in pots or tubs and the early forced bulbs.

One might say much more as to the beauty, the variety and the cultural adaptability of the best of the Christmas Roses, but it would not be at all easy to say too much in praise of these old-fashioned and historical inhabitants of our gardens, which have been popular from the most classical of Greek times, have lingered with us through the days of Turner, Gerard, Shakespeare, Queen Elizabeth and John Parkinson, and are with us now in a beauty, a quantity and in a variety never known nor so highly appreciated before in human times. It is not necessary for me to say that the plate by Mr. Moon gives a faithful picture of *H. altifolius*. As will be seen from the context above, the size of the flower is by no means exaggerated.

F. W. BURIDGE.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**MARROWS IN FRAMES.**—These, where planted out as soon as the earliest frame Potatoes were lifted, will now be in a bearing state and of such a size as to require much more root moisture and nourishment than before any fruit was formed. If the plants have reached the sides of the frames the lights must be entirely removed and the Marrows allowed to ramble over the sides and ends. Go over the plants and thin out any weakly growths, these being of no use, but rather a hindrance by excluding sun, air and light from the more robust fruitful growths. It is a good plan at this stage to mulch over the surface soil for some distance round the stems with good rotten manure, as Marrows want much moisture. A good soaking of farmyard liquid, diluted to one half its strength, once in ten days or a fortnight will be of immense benefit to Marrows. Do not allow any of the fruit to remain on the plants when fully grown, as this has an impoverishing effect, and Marrows will keep in a usable condition for some considerable time if placed in a dark cool place on a brick floor. Where a few Marrow plants have been grown in large pots under glass for early fruit they may now be thrown away, those in the frames taking their place.

**LEEKs—MAIN CROP.**—It is now high time the final planting of Leeks was made. These are best grown in trenches, except on strong retentive soils, when planting on the level is advisable. In any case work in plenty of the richest manure procurable, that from the piggery suiting them well so long as it is not in a green, rank condition. Some growers when ground is scarce plant three or even four rows in each trench, and good Leeks may be so grown, great care, however, being necessary in earthing up to prevent the soil from falling into the hearts. The trench or level plot should be well soaked with water the day before planting, and the seed-bed also, the young plants being carefully lifted with the aid of a small hand fork in order to preserve intact all fibrous roots. When planting cut a small portion of the top off with a sharp knife and sink the plants in holes made with a dibble, so that the foliage is just below the ground level, watering afterwards with a rose, and if in an exposed situation, afford shade for a fortnight by means of evergreen boughs as recommended for Celery trenches. Of course, where ground is no object, the one row trench is the best from every point of view. If any young plants are left after all the trenches are filled, they may be planted somewhat thickly on any spare well-manured piece of ground, these proving very useful for drawing early in autumn for flavouring purposes. The Lyon, Musselburgh and Aytou are all excellent sorts, Musselburgh being perhaps the best keeper and less liable to run to seed in hot, dry seasons. Dobbie's Champion, a

newer variety, is also excellent and especially adapted for exhibition.

**PEAS.**—The past few weeks have in most localities proved most trying to second early Peas, owing to absence of rain and parching winds. In very large gardens where labour is not over-abundant mulching and watering cannot always be carried out, and on light, porous soils the haulm soon gives way at the bottom, the first lot of Peas do not swell to their normal size, while secondary blossoms fail to set at all. In such places, however, there is usually a considerable quantity of Grass mowings, and these when wheeled off the lawns may be taken to the Pea plots and tipped in heaps, being afterwards levelled equally along the sides of the rows. One good soaking of water over this will often work wonders and keep the haulm in growth until rain comes. On moist ground where any tall-growing sorts have out-grown the stakes, topping the terminal shoots may be practised, this preventing the haulm from falling about and encouraging the poles to fill up quickly. If the growth has fallen through between the stakes, strong string may be used to keep it in its place, this being secured to a stout stake at intervals. May crops sufficiently grown should be staked without delay, as if once they fall over they never do so well after. Where it is desired to make another sowing for extra late purposes, Chelsea Gem will be found as good as any, the rows being about 3 feet apart. Keep all pods closely picked from rows now yielding, as this will give the successional pods an opportunity of filling properly during such hot, trying weather as we are at present experiencing. Let all first and second earlies be cleared from the ground as soon as the crop is gathered, if only for appearance sake. The ground will often come in useful for late greens, or the earliest plantings of Rosette Coleworts.

**ASSISTING CROPS.**—As weeds are not so troublesome as usual this summer, and are soon destroyed when hoed up by the hot sun and wind, all spare time may well be utilised in feeding all growing crops, either by the use of liquid manure or approved fertilisers. If the latter is used the best way is to water the ground around and between the crops the day before, then put on the manure, again watering it home. This is far more effectual than sprinkling it on perfectly dry ground and then watering. Globe Artichokes, Seakale, Asparagus beds, and, indeed, all similar rooting subjects can scarcely have too much moisture during the growing season. If any more offsets have issued from the Seakale plants since the growths were reduced to two or three, they must be removed at once, watering may also then more easily be performed. All small-growing subjects, such as Parsley, Radishes, Lettuce, and salads generally, are all the better for being watered in the evening, the roots then getting the full benefit of it; whereas if carried out during early morning much of the moisture is lost in evaporation.

**WATERING CELERY.**—The earliest planted rows of Celery will now be growing freely, and must not on any account be allowed to suffer from want of water. Feeding also will be needful, but strong manurial liquids such as blood, so much in favour amongst some cultivators, are not to be recommended, these imparting an unnatural and unpleasant flavour to the Celery. Their use also lays the crop open to disease and rot by promoting a sappy growth. Nothing surpasses good farmyard liquid for Celery; this may be poured into the trenches through a rose, and thus lashing the soil away from the root avoided, as is sometimes the case when spouts only are used. After watering with roses, however, a good overhead cleansing should be given with clear water.

**EARLIEST TOMATOES.**—In many cases these will have now reached the limit of their trellis room, and fruit will have set up to that point. In cases where fruit set badly towards the lower parts of the plants, a few shoots may be laid in over the old stems, removing a portion of the foliage to avoid crowding. These may be pinched when they reach that portion of the plant bearing green or half ripened fruit. Our earliest plants are fruited

in a lean-to structure occupying a shelf close to the front lights, and are trained up a trellis on the single rod system, all side laterals being removed as they appear, while the leader is allowed to grow on till the top of the trellis is reached. Beneath the shelf in question, however, and at some 2 feet distant, there is a second which accommodates an additional row of plants brought on at a later date. As the crop ripens and is cut from the lower parts of the first batch of plants the growths of the others are trained up immediately by their sides, the leaves of the former being removed by degrees. By this double batch system even in a moderately sized house the quantity of fruit obtainable is astonishing. The one-rod or stem system has much to recommend it over the pinching or many-branched, inasmuch as the fruit, though produced in somewhat less numbers, is much finer, and the aggregate weight is as great. I am growing Webb's Sensation this season and find it a capital variety for table use, being so round and handsome and of a most brilliant colour; it is also a good cropper. Should the dreaded disease appear, dust the foliage over with dry flowers of sulphur, keeping a dry atmosphere; this if not actually curing it will certainly greatly mitigate it.

J. CRAWFORD.

#### HARDY FRUITS.

**APRICOTS.**—The trees in this district are not heavily laden with fruit, but they require ample attention in the way of moisture, stopping or pinching. The shoots should now be pinched quite hard, as this will give more light to the fruit, causing it to colour and swell freely, and the trees will make fruiting spurs for another season. Much better leaders will be secured by timely stopping of useless wood, and these shoots should be lightly secured, leaving space for each to swell, as if checked in growth, gumming and canker will ensue. With regard to young trees, much better results are secured by allowing a freer growth, nailing in laterals, and allowing the main shoots to cover a large space in one season. By this plan the wall is more quickly covered and there is less disease. Young trees in some cases do not make a good start the first season, but when they do they should be encouraged, and not checked in any way by pruning; pinching lateral growths will be sufficient. If in time grossness should prevent free fruiting, it is well to lift in the early autumn before the leaves change colour rather than use the knife severely. My advice may be contrary to the usual practice, but I have to treat these trees differently on account of the frequent loss of branches, and I have found by allowing free growth there is less of this trouble. It is well to grow a few young trees to take the place of old ones, as the latter are so uncertain in their behaviour. With protracted drought few fruits require more moisture. On light soils the trees often suffer, as after the severe drought of 1893 the trees the following season lost many branches. Mulch heavily and water freely, doing the work in the evening, as then the moisture is retained longer. The mulch for young trees should not be rich, strawy litter being best.

**PEACHES AND NECTARINES.**—**YOUNG TREES.**—I have rarely seen these trees more healthy and so free from fly, curl, or blister. This may not be general in all parts, but in many trees it is hereditary. As new trees can be grown so quickly with generous treatment, I would advise giving more attention to those kinds which do succeed, removing those which are troublesome and bad growers. Where Peaches and Nectarines do thrive it is well to grow good hardy kinds. Lord Napier is my favourite inside or outside Nectarine. Such Peaches as Early Alfred, Hale's Early, Dymond, Barrington, Belle-garde, and Noblesse generally do well, and among the new Nectarines, Rivers' Orange, Dryden, Humboldt, Advance, and Pine-apple promise well. My object in giving this selection now is to enable those who wish to purchase to see their trees in a growing state, and in a measure judge of their mode of growth and fruit-

ing, as during the next two months they will be at their best. Time will also be gained at the planting season if the trees are marked and planted early.

**MANAGEMENT OF WALL TREES.**—These will now require more attention. The trees where well attended to have made a splendid clean growth, and thus will now require to be carefully nailed or tied and the terminal shoots placed in position. If due attention was paid to disbudding, the shoots may be readily placed in position, but crowding should be avoided, and it is far better to cut away growths not required for furnishing to the third or fourth leaf in preference to nailing them in. It is also well to stop at this season gross wood, and so divert the flow of sap into weaker shoots. By giving the terminals more space, strong lateral growth, which is often cut away, may be nailed in and made fruiting wood. By this means a wall is furnished much sooner, and there is less trouble with gumming and canker. Should the trees grow too strong, the same measures may be taken as advised for Apricots. Watering and mulching should not be delayed, especially on

*Iris atrofusca.* Engraved for THE GARDEN from a photograph sent by M. C. G. Van Tubergen, Junr., Haarlem.

light soils, thoroughly wetting the foliage as well in the evening. This will promote a luxuriant growth and keep red-spider at bay. Now is a good time to finally remove the fruits not intended to stone, as there need be no fear of dropping now. Any fruits hidden by leaves should be exposed to get good colour, removing useless leaf growth, also any nails bearing on well-placed fruits. Borders that are not moistened by syringing frequently should be flooded occasionally and well mulched, and should sudden changes of weather cause mildew to spread, lose no time in applying some mildew specific or dusting with sulphur.

**CHERRIES.**—With ripe fruits hanging and the trees much exposed in light land, there will be trouble with black fly, and the terminal shoots will soon suffer unless cleansed. To prevent injury to ripe fruit, dipping is the only remedy available, and quassia extract or tobacco water may be used, but whatever is employed must be used thoroughly, as a few insects soon breed and cover the growths. Fereight or lateral growth in a dirty state may be removed, but with young trees it is important to keep the terminal growth or leaders clean till the season is advanced and growth more matured. Syringing late varieties

and Morellos will still be necessary, and if infested with fly, the remedies advised above will be beneficial till the fruits colour. If Morellos are heavily laden with fruit, it is advantageous to remove small, poor fruits, thus allowing those left more space. The trees should be gone over and any fereight shoots cut back to a few eyes; this will make the wood into fruiting spurs. The trees should be mulched, as advised for other fruits, and watered. G. WYTHES.

## FLOWER GARDEN.

### IRIS ATROFUSCA.

THIS fair member of the attractive group of Cushion Irises was discovered in the spring of 1891 on the mountainous region which extends along the east side of the river Jordan. Broadly speaking, it may be described as an *Iris susiana* with much deeper coloured flowers. The accompanying engraving gives a good idea of the general appearance of the flower. The standards are of a dark lilac-brown with radiating veins of black, the falls are strongly recurved and of a blackish brown colour. When seen in good condition it is a really fine and striking plant. As to culture, this species requires no more special care than the other members of this group, but it sometimes gets spoiled by late frosts, which nip the foliage and cripple the plant.

C. G. VAN TUBERGEN, JUN.

### A ROCK GARDEN.

I HAVE lately had the opportunity of inspecting the rock garden at Abbotsbury, Newton Abbot, South Devon. In the pool, which is contained within the confines of this garden, five varieties of *Nymphaea* were flowering, and formed an exceedingly attractive sight. *Nymphaea Marliacea Chromatella*, with its delightful blooms of pale saffron; *N. M. carnea* and *N. M. rosea*, the former suffused with a delicate flesh colour, the latter of a deeper tint, approaching a rosy pink; *N. Leydekeri rosea*, bearing blossoms of a lovely rose colour, no two blooms being precisely of the same tint, owing, in all probability, to the difference in age of the individual flowers; and *N. pygmaea alba*, with its white chalcies, completed a picture beautiful both in colour and in form such as is too seldom seen in our gardens. These Lilies are all hardy, and planted in good soil and in not too great a depth of water can scarcely fail to succeed. The piece of water in which these Lilies were growing is irregular in shape and of no great extent. The edges of the pool are fringed with *Iris*, *Mimulus*, and *Spiraea*, the water that supplies it rising from under a large rock, its source half hidden by Ferns. After a short course over rocky slabs and beneath overhanging outcrops of stone, the streamlet reaches a rough rock staircase from 8 feet to 10 feet in height, and thence descends by the side of a craggy rock pile to the level of the pond, leaving it at the lower end to meander for a little distance through less rugged environment ere losing itself, as it sprang into life, beneath a rock.

Around the streamlet, which is here and there spanned by great slabs of stone, reminding one of the covering stones of the Megalithic bridges of the ancients, which still exist on Dartmoor, and on the surrounding inequalities of the ground many plants were in bloom. On one rocky mound the Iceland Poppies, yellow, orange, and white;

on another, *Papaver pilosum*. A fine plant of *Romneya Coulteri* was showing its flower-buds. *Eriogonum Youngii* was in full bloom, and the chaste (*E. marginata* expanding its large white cups. Tree Lupins, varieties of the *Cistus* family, Saxifrages in quantity, *Heuchera sanguinea*, with its ruddy flower-spikes, *Campanulas*, *Aubrietas*, *Centaureas*, and *Coreopsis* added their varied tints to the grey of the stones and the green of the Ferns that grew in the interstices of the rocks. Near a clump of the American Cowslip (*Dodecatheon Meadia*) a colony of *Edelweiss* had expanded its quaint flowers, and in a damp spot the Cotton Grass (*Eriophorum*) waved its heads of white, feathery down. Where the rocks ceased or became more broken, the Day Lily, *Alstroemeria*, *Erigeron speciosus*, and *Inula glandulosa* were in flower, while in the background clumps of *Delphinium* reared their tall blue spires.

S. W. F.

THE ROCK GARDEN.

X.

JUNE 18.—The weather has been warm and rather dry for the last few weeks, and rock plants of every description are now blooming in such abundance that to give even a list of their names alone would occupy a very considerable space. I will therefore mention only the best of such plants as are now in bloom in this county (Devon).

CHOICE ROCK PLANTS NOW IN BLOOM SUITABLE FOR SELECT PART OF ROCK GARDEN.

Perhaps one of the smallest and neatest plants now blooming is *Saxifraga caesia*, which does best planted in a sloping position wedged in between stones. The very minute silvery rosettes form a compact, hard cushion, from which spring numerous flower-stems about 2½ inches or 3 inches high, each bearing a corymb of eight or ten white flowers. *Dianthus alpinus* is now past its best, but other gems are taking its place, the best and choicest among them being *D. callizonus*, *D. neglectus*, and *D. Reuterianus*. *D. callizonus* is still very rare. At Exeter it is flowering side by side with *D. neglectus*. The flowers of the former are larger than *D. alpinus* and of a similar shade of bright pink, but the centre of the flower shows a very distinct dark zone spotted with white. *D. Reuterianus* has flowers similar to *D. neglectus*, but the foliage resembles *D. alpinus*. *Phyteuma comosum* requires a position similar to that just recommended for *Saxifraga caesia*; it is now at its best, and its large purple flowers of peculiar shape make it an object of great interest. The Siberian *Edelweiss* (*Leontopodium sibiricum*) is also in full bloom. Three of its woolly bracts are nearly half an inch wide, and as they are longer than the rest, the flower has an almost triangular appearance. The taller Himalayan *Edelweiss* is only just opening, but the well-known alpine variety has been in bloom for a week or more. All three do best in calcareous soil fully exposed. *Potentilla nitida*, with its silvery carpet of leaves and large white or pink flowers close to the ground, is very beautiful, and forms a capital contrast to *Edraianthus pumiliorum* and *E. graminifolius*, which are still very showy with bright purplish blue flowers. A good yellow companion to these is *Vella spinosa*, with *Draba*-like foliage and bright golden yellow blossoms. *Asperula nitida* (described on page 417 of THE GARDEN) is just passing out of bloom, but its neat cushion of crumpled leaves is highly ornamental, even without the pink flowers. Very pleasing just now are the bright pink flowers of that pretty little evergreen, *Acantholimon glumaceum* and the large pink

flowers of *Geranium subcaulescens*. Several plants now in full bloom, though certainly in their right place in the select part of the rock garden, require, nevertheless, more space than those mentioned above on account of their spreading shoots, which should be allowed to fall gracefully over the stones. Of this class I will only mention the mauve *Androsace lanuginosa*, its white carmine-eyed variety, *A. Leichtlini*, the Fire Pink (*Silene virginica*) and the beautiful yellow *Saxifraga flagellaris*, described in THE GARDEN of June 22. Larger choice plants of more erect growth now in bloom are *Lithospermum graminifolium*, with tubular flowers of bright cobalt blue; *Lithospermum petraeum*, of more shrubby habit and broader leaves; *Androsace foliosa*, which requires a sheltered nook and is the largest of all *Androsaces*; and last, but not least, that bright yellow flower, *Haplocarpha Leichtlini*, referred to in THE GARDEN a week ago.

FLOWERS BY THE WATERSIDE.

Of the numerous bog plants now in bloom I will mention only a few of the best. *Pinguicula longifolia* and *P. Reuteri* are both charming plants for the bog bed, but owing to their very small size they deserve a prominent position where they could not be overrun by some of the taller and coarser kinds mentioned hereunder. *P. Reuteri* has large pale pink flowers and a darker throat striped with purple, while *P. longifolia* has smaller, but deep blue flowers. Probably there are several other *Pinguiculas* in bloom, but those mentioned are the only ones which have come under my observation. Among Orchids now in bloom I noticed the white sweet-scented *Habenaria cephariglottis* (from America), *Gymnadenia odoratissima* (alpine meadows), *Orchis maculata*, and *Orchis foliosa*. Of *Primulas*, the large flowers of the well known *Primula japonica* and the yellow *P. sikkimensis* are now the most conspicuous; both prefer a shady nook. Of the plants now in bloom several kinds suitable for the bog garden grow so large, that they must be kept at a sufficient distance from the choicer rock plants, and as they are most effective they are well worth a little extra care. For single specimens I would recommend *Spiraea gigantea*, which grows 6 feet or 8 feet high; *Senecio japonicus*, with deeply divided leaves and large yellow flowers, and the well-known *Podophyllum peltatum*, all of which are in full bloom at the time of writing. Many waterside plants more effective in groups than as single specimens are also now at their best, as, for instance, *Spiraea palmata*, *S. p. alba*, *Astilbe rivularis*, *Spiraea filipendula*, *S. astilboides*, and many varieties of the Day Lily (*Emerocallis*). *Iris germanica* is just passing out of bloom, but the *I. Kämpferi* varieties are only just beginning to expand.

DIANTHUS NOW IN BLOOM.

I have already mentioned a few of the smallest and choicest kinds of *Dianthus* now in season, and will here enumerate some of the stronger-growing kinds suitable more for effect among the rocks generally than for the select part. The number is so great, that a full description would be far beyond the limit of these notes. The tallest kinds now in bloom are *Dianthus atrorubens* and *D. cruentus*, both with deep blood red flowers; *D. plumarius*, *D. glaucus*, *D. Seguieri*, and *D. arenarius* are white, changing to pink. Of the *D. hybridus* multiflorus type, two capital representatives in full blossom are *D. Napoleon III.*, fiery crimson, and *D. Marie Pare*, white, striped with pink. Of smaller kinds, I will mention *D. alpestris*, pink; *D. annulatus*, white, with deep crimson ring in centre; *D. integer*, fringed

white; *D. superbus*, pink, deeply fringed; *D. sylvestris*, bright pink; *D. suavis*, white; and last, but not least, the charming little Cheddar Pink (*D. caesioides*). All the varieties mentioned are now blooming simultaneously, and the effective combinations that may be produced by skilful grouping are without number.

CAMPANULAS IN BLOOM.

*Campanulas* are excellent companions to the *Dianthus* both with regard to season of blooming and contrast of colour. In rock gardens where a large number of *Dianthus* are grouped together in one part, and *Campanulas* of all kinds adorn an adjoining group of rocks, the effect is most striking, especially if the blue, white, pink and crimson tints of colour are allowed occasionally to intermingle with each other as we might find them in the Alps. The *Campanulas* now in full bloom are very numerous indeed. Some of the smallest and choicest are *C. Raineri*, *C. cenisia*, *C. Erinus*, *C. Waldsteiniata*, *C. pulla*, *C. turbinata*, *C. G. F. Wilson*, *C. garganica*, *C. garganica alba*, *C. alpina*, *C. pumila* and *C. pumila alba*. As none of these spread very fast they may be planted at a short distance from each other. The following, however, require more room as their habit is more robust: *C. Portenschlagiana*, *C. mollis*, a grand form with large blue flowers 6 to 8 inches high; *C. rhomboidea alba*, a splendid white variety about 1 foot in height; *C. hirsuta*, pale blue; *C. barbata*, porcelain blue; *C. caespitosa*, *C. carpatica*.

Besides these there are now many taller varieties in bloom which would be most suitable for a background or for isolated specimens among smaller plants. One of the grandest forms for the latter purpose is *C. persicifolia alba grandiflora* (Backhouse's variety), which altogether eclipses the well-known ordinary white and blue forms of *C. persicifolia*. The bright purple *C. glomerata dahurica* looks best in groups perhaps adjoining Iceland Poppies, with which it flowers simultaneously and forms a capital contrast of colour. *C. celtidifolia* and *C. macrantha* are both excellent for background work.

F. W. MEYER.

Exeter.

(To be continued.)

FLOWER GARDEN NOTES.

PEONIES.—*Peonies* followed very closely this year on the heels of *Pyrethrums*, and in many cases were contemporary with the latter flowers. Few herbaceous plants have come more prominently to the front in a comparatively short time than the single and double *Peonies*, the latter especially in great variety, being found in the majority of gardens where a brilliant display and plenty of cut flowers are required. When cut it is advisable, both in the case of the double and single flowers, to cut the blooms as they are emerging from the bud stage, or at most about three parts expanded, and if wanted for packing to send a considerable distance on a given day, they should be cut the previous night and placed in water. Moisture and shade are sometimes said to be essential to the growth of *Peonies*, but this is hardly correct. The very fine display at Messrs. Barr's at Long Ditton is on a dry sandy soil and in the full blaze of the sun, and, so far as soil is concerned, our clumps are similarly situated. As a matter of fact, *Peonies* will do well anywhere if at planting time they get the benefit of deep tilth and a liberal dose of good manure. If the natural soil is somewhat light it is advisable to press it very firmly about the plants, and also to give a good heavy mulching when the planting is finished.

POT PLANTS FOR THE FLOWER GARDEN.—These we have to use rather extensively to make up for a scarcity of flower beds, and I never remember a better display so early in the season. The situa-

tion being bleak and liable to be wind-swept, I find zonal Pelargoniums in variety and Marguerites the best plants to furnish the colour required. The Pelargoniums are the plants that have already done service through the winter months; they get a special top-dressing early in spring and bi-weekly feeding with a fairly strong stimulant as soon as they come into flower. To secure bushy plants they are cut over rather hard about the latter end of February, withholding water for a time previous to that date to ripen the wood, and shoots as they advance are pinched back especially in the case of strong growers. The free flowering doubles in various shades are, however, the most useful for this out door pot work. Marguerites possess the merit of growing quickly to a large size (if one can keep the maggot from them) or they will flower profusely in 5-inch pots. Trained specimen plants grown are Fuchsias, Heliotropes and Aloysias. In shady situations a few nice plants of the Sweet Tobacco do admirably, and form an admirable contrast, especially in the cool of the evening, to the bright colours of the Pelargoniums and Fuchsias. When large masses of the Tobacco are required a little seed is sown early in February, the plants shifted as soon as they can be handled, and potted on for a final shift into 6-inch pots, pinching out the centre to secure several breaks. A similar wealth of *Francoa ramosa*, another very useful plant for the work, is secured by retaining old plants and staking out the spikes as they develop. The two best Fuchsias for specimen work are the old Rose of Castile and Duchess of Edinburgh, a very vigorous variety with a large purple corolla and brilliant scarlet sepals. Where summer groups of plants are required and house accommodation is limited, the desired end can be partially attained by utilising a collection of hardy plants, as scarlet Lobelias, Funkias, *Hemerocallis*, *Spiraeas*, *Lilium candidum* and the like. They should be potted up in early autumn in a bit of good soil and kept in a cold frame free from frost through the winter months.

**VASES AND WINDOW BOXES.**—These should be kept if possible full of flower and in all cases scrupulously neat and tidy, blooms past their best being promptly removed not only for appearance sake, but that the rapid succession of flower can be the more readily secured. It is always advisable to leave a little stock of plants to fill up any gaps that may occur. This year, for instance, we lost several Ball of Fire *Tropeolum* that were used as an edging to white Marguerites, but were able to fill up the gaps with some good plants of a double pink Ivy-leaved Pelargonium. A great point in the filling of vases and boxes is to use thoroughly good sturdy plants that have also been well hardened off. They come away quickly and soon furnish the places assigned them. I have before referred to the value of *Petunias* for such work, and this year they are doing remarkably well; the varieties grown are Giant of California and Empress, both very free and vigorous, and throwing flowers of extra size and quality. East Lothian Stocks are by no means to be despised for the back and centre of window boxes with something planted in front as a trailer. It may be noted in connection with boxes and vases, as also with all pot plants used for grouping, that so soon as they are full of flower something in the way of a stimulant must be employed to keep existing growth healthy and fresh and to encourage the steady progress of the same. The majority of artificial manures leave behind them an odour that would be very objectionable in the immediate neighbourhood of the dwelling-house, and I have found nothing better as a stimulant than liquid manure made with fresh cow manure; there is a staying power in this that is just the thing for all soft-wooded pot plants.

**CARNATIONS.**—As the stock of border Carnations saved over from the winter of 1894-95 is not in the majority of places a large one, some varieties having totally disappeared, every bit of grass, however small, will have to be utilised for layering. It is not likely to be a matter, as in 1891, of choosing a few of the best shoots from each plant. I have before noted the advisability

of putting a small quantity of soil nearly all over the border rather than heaping up high mounds immediately round the plants. Our four most reliable sorts, Countess of Paris, Raby, Mrs. Reynolds-Hole, and Murillo, have come through the winter very well, and to these may be added Goldfinder and Sir Beauchamp Seymour. The old crimson and the white Cloves in one or two varieties have suffered most. Where, in the course of layering, a slip of the knife leads to the severance of a shoot, it will doubtless be found advisable to insert it as a cutting, and it may go in the bed prepared for the Pinks, taking care to water and shade for a short time until root action has commenced.

Claremont.

E. BURRELL.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL ROSE SOCIETY.

GLOUCESTER. JUNE 27.

ROSES have come on so rapidly during the past fortnight, and the weather has been so hot and dry, that we shall not be far wrong in saying the season of their most general beauty and greatest quantity is fast disappearing. There is usually a period of from two to three weeks when almost every grower is in "full cut," and this has been earlier than for many seasons. The chief event of last week was the National Rose Society's exhibition at Gloucester, where a most successful show was held in connection with the Gloucester Rose Society. So good were the Roses throughout and numerous the competitors in most classes, that more than one looked upon it as the best provincial show held by the N.R.S.

Messrs. R. Harkness and Sons, Bedale, Yorkshire, were the winners in the premier class for trade growers, staging a magnificent forty-eight single trusses of distinct varieties. As no less than eight competed here, and such redoubtable growers as G. Paul and Son, Cheshunt, F. Cant and D. Prior and Sons from Colchester, also G. Mount, Canterbury, and The English Fruit and Rose Company, Hereford, were unsuccessful, it is proof of the sterling quality of the winning stands. Messrs. Harkness had the silver medal Hybrid Perpetual here, but the winners of these will be described in due course. Mr. B. R. Cant, Colchester, was a good second. The same order was observed in the class for twenty-four varieties, three of each, but ten or eleven competed in this case. The twelve blooms of Lady Mary Fitzwilliam that took first for Mr. B. R. Cant were simply magnificent. The class of the day, however, was one of twelve singles, open to all amateurs, and here Rev. J. H. Pemberton won the silver cup presented, a silver-gilt medal going to Mr. E. B. Lindsell, who was somewhat unfortunate not to be first, and would undoubtedly have been so a couple of hours later. The silver medal and the bronze medal went to Mr. J. Parker, Hitchin, and Mr. W. Drew, Ledbury. There were sixteen competitors, and all of the stands were good. The class for twenty-four singles was also strongly contested, Mr. Walter Drew beating Mr. E. B. Lindsell. Eleven competed in a class for six trebles, distinct, and here the order was reversed, Mr. E. B. Lindsell having some of the grandest flowers in the show. Mr. George Moules, of Hitchin, was fortunate enough to carry off two first prizes with the only two boxes he brought, and this in by no means weakly contested classes—a great encouragement to small growers. Horace Vernet was shown well, most of the leading stands containing this grand dark Rose; so also was Her Majesty.

When we come to the Tea and Noisette section it is difficult to say enough in their praise, but we were sorry to miss the Oxford Roses here. None of those grand boxes of Comtesse de Nadaillac were seen, although the variety figured well in various stands. The twenty-four blooms from D. Prior and Son, Colchester, were simply perfect.

In the premier class for Teas among amateurs the first also went to Colchester, Mr. O. G. Orpen being successful and beating the Rev. A. Foster-Melliard, who was second. There was a grand dozen of Marie Van Houtte staged by Messrs. D. Prior and Son for twelve of any Tea or Noisette. Mr. B. R. Cant, F. Cant and D. Prior and Son won the prizes for twelve distinct Teas (three of each), and open to all England, amateurs or nurserymen. We were not so much impressed by the garden Roses, nor by the "displays" as usual. No new Rose was put up worthy the name, and no award was made. The Penzance Sweet Briers were good, and we have evidently not exhausted or by any means come to their chief beauty. Among the new ones was a bright semi-double called Jeannie Deans, which is more promising than any of those yet in commerce. There was a very pretty arrangement of arches covered with Roses shown by Messrs. Phelps and Co., Cardiff, that drew much attention. Mr. Conway Jones, Hucclecote, was remarkably successful both in the general classes and those confined to local growers. The silver cup for eighteen singles, the silver medal for six Teas, and the silver salver presented by the corporation for twelve singles fell to his share among the local prizes. Ernest Metz was good in many cases. It is somewhat singular that so often the silver medal Roses should be found in indifferent growers, or those that only produce a good bloom now and again. If we except Catherine Mermet, The Bride, A. K. Williams, Mrs. John Laing, Gabriel Luizet and a few more, we find weak growers and uncertain bloomers often giving us a bloom of extraordinary merit. Last season it was Cleopatra and Margart Boudet. At Gloucester the Hybrid Perpetual in the nurserymen's classes was Comtesse de Ludre, a Rose seldom seen, although it was sent out so long ago as 1880. The specimen here was simply perfect in every way, but the usual growth of this variety is not what one would wish. The other medal Hybrid Perpetual was Horace Vernet, and all of us know what a disappointing grower this is, although it so often produces a magnificent specimen flower. La Boule d'Or and Ethel Brownlow (the two silver medal Teas) are not among our best growers, and it is only during exceptional seasons that we find really first-class blooms of them.

### GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE annual dinner of this institution took place on Friday, June 28, in the Whitehall Rooms, Hotel Metropole, the Duke of Fife, K.T., in the chair. The subscriptions realised a large sum, not too large, however, to make one feel content that such an institution as this is receiving sufficient support.

The tables were delightfully decorated with the choicest flowers and fruits contributed by many nurserymen and gardeners, and it would be safe to say that at no dinner are the tables more beautiful than at the annual gatherings of the Gardeners' Royal Benevolent Institution.

There was a large company present, amongst those we noticed being Sir Trevor Lawrence, Bart., the Rev. W. Wilks, and Messrs. G. A. Dickson, J. G. Veitch, J. Hudson, J. Douglas, G. Norman, W. G. Head, J. Protheroe, H. Turner, A. W. G. Weeks, H. Williams, H. J. Cutbush, A. F. Barron, P. Barr, G. Gordon, G. Wythes, W. Poupert, G. Monro, J. Walker, David Syme, T. F. Kivers, W. J. Jeffries, N. Sherwood, and W. H. Cutbush.

The Duke, who was received with tremendous cheering, proposed the usual loyal toasts, and the toast of the evening, "Continued Success to the Institution." He said that the Gardeners' Royal Benevolent Institution "was the only one of its kind in Great Britain. Its great object was to assist the aged and infirm by means of pensions, and to inculcate the admirable principle of self-help by giving a preference to those who had subscribed to its funds." All gardeners, the chairman said, were not in the employment of the rich.

Most of them had to toil unceasingly, and, unfortunately, misfortune overtakes many of them. To assist such this society was founded in 1838, and since then it had distributed in pensions and gratuities about £65,000. At the present time 156 persons were receiving permanent assistance—77 men and 79 women—while there were 36 pressing cases on the list. The pensions were originally £16 per annum to men and £12 per annum to the women, but the amounts were increased in 1885 to £20 and £16 respectively—not, he thought, an exorbitant sum. Persons of 60 years of age and upwards if incapacitated from work, and if they comply with the rules, or younger in case of total disability, are eligible for pensions.

This toast was responded to, in the unfortunate absence of the treasurer (Mr. Harry J. Veitch) through ill health, by Mr. George A. Dickson. He said everyone, he felt sure, in the room would regret the absence that evening of Mr. Veitch, who worked so nobly for the institution; and in the course of a lengthy speech mentioned that the funded property of the institution consisted of £25,000 consols. Of that sum £20,000 had been recently invested, with the result that the income was increased by £50 a year; but greater support was needed. Their assured income was only about £800, whereas their liability for pensions alone was £2804, to say nothing of funeral expenses, which were sometimes granted in exceptional cases. Out of 50 candidates at the last election only 14 could be elected. Mr. Dickson therefore said he must join with the chairman in appealing for further support. An additional assured income of £700 was necessary if the committee were to meet all the claims.

"Horticulture" was the title of the next toast, proposed (in the absence of Sir J. Whittaker Ellis, Bt.) by Mr. W. J. Jefferies, of Cirencester. Sir Trevor Lawrence responded, mentioning that great progress had been made of recent years in every department of horticulture. "The Health of the Chairman" was proposed by Mr. Sherwood, and the toast was received with great applause.

"The Health of the Secretary," Mr. G. J. Ingram, was proposed by Mr. Dickson and received with enthusiasm. Mr. Ingram, in reply, said that in these days of depression it needed something more than stereotyped circulars to sustain interest in any institution.

"The Stewards" was proposed by Mr. Arnold Moss, and responded to by Mr. G. Monro.

In addition to the sums already acknowledged, the following were announced as having been received, making up a grand total of £1900 with the sums already advertised: The Duke of Fife, £30; Mr. C. Czarnikow, 10 guineas; Messrs. J. Veitch and Sons, £25; Mr. N. Sherwood, £21; Messrs. Rothschild, £105; Alfred de Rothschild, £10 10s.; Mr. G. Monro, 105 guineas; Mr. G. J. Braikenridge, 8 guineas; Mr. G. W. Dawes, 10 guineas; Messrs. Protheroe and Morris, 5 guineas; Mr. J. Coleman, 5 guineas; Sir Trevor Lawrence, 10 guineas; Mr. E. Stern, 10 guineas; Mr. G. A. Dickson, 5 guineas; Mr. G. Profit, £21; Mr. G. Maycock, 10 guineas; Wm. Thomson Memorial Fund, £98; part proceeds of 3rd edition of "Cypripediums," by R. I. Measures, £7 10s.; Mr. J. Lee, 5 guineas; Mr. E. V. Low, 5 guineas; Mr. W. G. Head, £5.

A letter was read from Mr. J. Lee regretting his absence from the gathering that evening, but he had now retired at the age of nearly 90 years, after having attended every anniversary except one, and that occurred on his wedding day. Such a record is a notable one. The institution has known no more devoted helper than Mr. Lee.

**The Royal Gardeners' Orphan Fund.**—A meeting of the committee took place at the Horticultural Club on the 27th ult., when the following special donations were announced: From the William Thomson Memorial Fund, £65 13s. 2d.; Mr. J. T. Anderson, Commercial Street, E., £1 1s. 0d.; Messrs. J. Laing and Sons, Forest Hill, £1 1s. 0d.; Mr. R. J. Measures, proceeds of sale of third edition of "Cypripedium Hybrid

Species," £7 10s. 0d.; Mr. A. Stirton, Wrexham, 5s. A cheque was drawn for £201 10s. 0d., the quarter's allowance to the orphan children of deceased gardeners, an amount which shows the value of such a fund to many widowed mothers left in difficult circumstances, and which should induce some who do not yet subscribe to at once do so.

#### NOTES FROM ALMONDSBURY.

THE drought here is very severe—'02 in. of rain since June 1—yet the garden does not seem to suffer very much. Roses have fairly survived the winter and their bloom is astonishing. No insect pests of any kind. The Bourbons are really magnificent. A hedge of mixed Japanese and Chinese, multiflora and rugosa, the Cherokee, R. Brunonis, and various Briars, about 30 yards long and in places over 12 feet high, is very charming. I find *Michauxia campanuloides* likes this weather very much and its strange flowers are the wonder of many. *Iris ochroleuca* is in full beauty and the bees revel in it. Then how gloriously the sun brings out the bloom of the old plants of *Geranium* of all kinds and colour! *Ipomoea pandurata* is struggling to get over a 14-foot wall. A seedling *Crinum*, with leaves 4 feet long and spike of bloom (delicate pink) a yard high, is in a corner of the greenhouse, and above it *Ipomoea rubro-cœrulea* is climbing over the roof. This year some hybrid *Streptocarpus* have bloomed most freely; in this heat I find they need to stand in water. The orchard is filled with bloom of Canterbury Bells and Evening Primroses—the result of emptying the ash-bin round the trees—the seeds arriving there from drawing-room blooms of previous years. On these hot nights the fragrance of Japan Honeysuckle is delightful about 10 p.m. *Iris Kempferi*, from clumps bought in March, is full of buds. I grow all in tubs near a pump and water daily. Then *Carpenteria californica*, to my delight, is full of bloom in a corner of the kitchen garden. White Carnations promise well. *Alstroemerias* are very tall and full of bloom. I am convinced that they like plenty of deep, damp soil and a hot sun. I have lost many clumps from neglect of this. I would place the next lot I have in a ditch filled up with rich soil, exposed to the afternoon sun. I have several clumps of pure white *Iris anglica*, and these have done well this year. Why does *I. hispanica* always fail with me? *I. Milesi* in the open border has bloomed finely.

C. O. MILES.

**Notes from Baden-Baden.**—*Cnicus Falconeri* is a stately plant; the hanging big heads on a much-divided stem look very strange. The leaves are large, dark green, and the flowers are white. *Lathyrus abyssinicus* is attractive from its clear ultramarine-coloured flowers. *Veratrum californicum* is showy on account of its large white flowers. In *Gerbeum Jamesoni* we have one of the most showy composites; its large brilliant crimson-scarlet flowers, which continue from April to November, are now at their best, enjoying the warmth of summer. *Tropæolum Leichtlini* rambling over some boughs is clothed in grey and deep yellow. *Gentiana Moorcroftiana* blooms very freely; the flowers are small, bright blue, and entirely hide the foliage. *Silene Hookeri*, now re-introduced, shows its starry white flowers, and a group of *Calceolaria alba* with its numerous blooms of purest white is quite charming. The succession of summer-flowering *Gладиoli* is opened now by *G. aurantiacus*, bright orange; *G. Leichtlini*, deep red, and a new species, greenish yellow with bright red streaks and points. I may mention the germination and growth of one of the most remarkable alpinines ever introduced. *Campanula mirabilis*, perhaps extinct for ever in its native home, is soon to adorn our rockeries with its wonderful flower pyramids.—MAX LEICHTLIN, Baden-Baden.

**Notes from Chester.**—We sent you last week flowering sprays of several varieties of the Mock Orange. There is yet another that is just now

exceptionally fine, *Philadelphus laxus*, which is of striking beauty, with its large flowers of pure white set so gracefully and emitting such a delicious fragrance. We think there is nothing finer in the range of varieties. The *Spiræas* are in fine array. *Spiræa Douglasi* is valuable on account of its compact, dense spikes of colour. *S. callosa*, with its bunchy heads of less pronounced pink, is also pretty. The sprig we send you of *S. Anthony Waterer* does not fairly represent the character of the plant, though it gives the glory of its colour. *S. flagelliformis* is so distinct as to render a second look needful to assure oneself that it is a *Spiræa* at all. *Hypericum Moserianum* is one of the showiest of the St. John's Worts. Its bold, brilliant flowers, with circlets of rosy tipped anthers, its finely arranged foliage, and its general habit make it a most desirable addition to this valuable family of hardy plants. *Cytisus nigricans* is a very showy species. Its long upright flowering spikes of rich yellow blossoms and its dark foliage give it a conspicuous appearance. Long rows of standards all in full flower make a quite unique feature in the ornamental garden. The herbaceous borders and quarters are every day presenting new features. The English *Iris* is now in full glory. The *Star of Bethlehem* (*Ornithogalum arabicum*) is also very fine. Its flowers are distinct with their white petals and almost black centres. In passing through the glasshouses there are some very delightful things in full bloom. *Dracophyllum gracile*, *Streptocarpus hybrids*, and *Tremandra verticillata* are all beautiful. The heavy rain of Wednesday last (when our rain gauge registered a rainfall of nearly 2 inches) has had a remarkable effect upon vegetation generally, and though fully expanded blooms were dashed and spoiled, everything now is looking fresh and healthy.—DICKSONS.

#### NOTES OF THE WEEK.

**Geranium argenteum.**—This is a dwarf, but pretty species that looks well in the rock garden. It hides the ground with tufts of shining silvery leaves and bears a profusion of pale lilac flowers in succession for several weeks.

**Edelweiss** (*Leontopodium alpinum*).—How beautiful and free the Edelweiss has been this year. For the last six weeks the large heads of woolly bracts have been most interesting. I should think the severe winter followed by such warm weather has been in its favour.—J. W. H., Worcester.

**Lilium Beerensi** is a pretty hybrid Lily now flowering with Mr. Ware at Tottenham. It is the result of a cross between *L. chalcedonicum* and *L. excelsum*, in leafage resembling the former parent, but the flower (more like that of *L. excelsum*) is of a deep apricot colour, with long, prominent, orange-scarlet anthers.

**An Australian garden.**—Mr. J. W. Porter sends us two beautiful photographs of his garden in Adelaide which show well the advances that have been made in gardening in this district and the fine climate enjoyed. The garden has only been planted about seven years. Sub-tropical plants thrive admirably, fine specimens of Palms, *Dracenas* and *Cannas* being prominent in the photographs sent.

**Campanula muralis var. Portenschlagiana.**—This *Campanula* has been beautiful during the last month and has been admired by all who have seen it. The plants, which cover a space of about 2 yards square, grow about 6 inches high, the flowers bright blue, shaded with purple, and much larger and deeper in colour than those of *C. muralis* which I have growing close by.—W. H.

**Helenium Bolanderi.**—This, one of the earliest flowering varieties of this showy family, appears to be able to resist the drought much better than many hardy flowers of the present time. A large bed of it in Mr. Ware's nursery at

Tottenham is a mass of bright colour. It is a compact grower about 1 foot in height, the flowers rich orange-yellow with brownish black centre.

**Lilium Parryi** is a handsome Californian Lily that grows well and flowers freely in Mr. Ware's nursery at Tottenham. It belongs to the pardalinum group and has rich yellow flowers spotted with black, strong shoots bearing a dozen or even more blooms. It is easily grown in moist peaty soil with the partial shade of shrubs near, and those who have a suitable place for it might plant a bold group.

**Codonopsis ovata**.—This pretty Bellflower does well in Mr. Ware's nursery at Tottenham, and is now in profuse bloom. It lacks the rich blue colour of most Bellflowers, but has a quiet beauty of its own. Its large drooping flowers, borne abundantly on strong erect stalks, are of the palest blue shade externally, but the inner base of the flower is most distinct with a zone of rich yellow surrounding the black stigma. It is a good plant for the rock garden.

**Centaurea ruthenica** is one of the vigorous growing hardy plants of the Composite family that few take any notice of, yet planted in a suitable position it would be valuable. The proper place for it is associated with shrubs in bold groups away from the beds and borders of choicer flowers. We noted a fine mass of it at Mr. Ware's, bright with many flowers, which are as yellow as those of the Sweet Sultan, quite twice the size and good for cutting.

**Sorbus majestica** and **S. nepalensis**.—The Pyrus and Sorbus families contain several very handsome trees of moderate size, but bold and varied in outline and beautiful in rich leaf growth. Two that we specially noted at Knap Hill are those above mentioned. **S. majestica** is of a pyramidal habit and carries a very dense head of large, deep green leaves. **S. nepalensis** is quite as robust as the preceding, but its leaves are grey-green above, quite of a silvery tint below, and lovely when the tree is waving in the wind.

**Delphinium grandiflorum fl.-pl.**—This old species is not often seen in gardens, and yet there is no more handsome flowering plant at the present time. A large bunch of it was conspicuous in Messrs. Veitch's group of hardy flowers on Tuesday at the R.H.S., and among the fine kinds there shown not one surpassed this for beauty and depth of colour. It is almost as blue as the Gentian, and the flowers, although double, are prettier than those of the double florists' varieties, and gracefully disposed in branched heads adapted for cutting.

**Magnolia glauca**.—This noble American Magnolia has been in the country about 50 years, and yet we very rarely meet with it in gardens. There is a good tree of it in Mr. A. Waterer's nursery at Knap Hill, and we were charmed to see it there a few days ago bearing many lovely flowers. It is almost evergreen and handsome in leaf at all times, the leaves being of a polished green above and of a pronounced glaucous hue beneath, which is seen to advantage in a tree 15 feet high. It wants a moist peaty soil, but it is a pity more do not grow it.

**Zenobia speciosa** and **Z. pulverulenta**.—These are certainly two of the most beautiful shrubs in the Heath family, combining graceful growth with lovely blossoms of wax-like substance and perfect purity of colour. **Z. pulverulenta** is peculiarly distinct and charming with its silvery shoots, the leaves and stem alike in colour. We noted a large batch of seedling plants in Mr. A. Waterer's nursery at Knap Hill, and although the seed was that of **Z. speciosa**, plants of **Z. pulverulenta** in its best form were also present in fair numbers.

**Weigela Eva Rathke** is a distinct and beautiful variety that will be valued not only for its deep rich colour, but for its late and successional blooming. We saw a quantity of it in Mr. A. Waterer's nursery at Knap Hill, and the plants were gay with flowers, whilst there were many

buds still to expand. Even small plants were wreathed in bloom, so that it flowers abundantly when young, but its effect when the bushes grow large and throw out their arching wands will be superb. It should be noted as a shrub to plant by those who have not got it.

**Brodiaea volubilis**.—This charming Brodiaea, in addition to its peculiar habit, so different from that of all other species, is besides handsome in flower, and a quantity of it shown in the group from Messrs. Wallace, of Colchester, at the Drill Hall on June 25 attracted much notice. It is rarely seen at all either at shows or in gardens, and yet there is no more difficulty in growing it than there is other Brodiaeas, only something for it to climb upon is most essential. The specimens shown were entwined around Bamboo canes 3 feet or more in height, and bore at the top of the canes close heads consisting of twenty or more flowers, which are of a deep rose colour.

## PUBLIC GARDENS.

**Royal Botanic Society**.—At a meeting of the council of this society, held last Saturday, it was decided to open their gardens, in Regent's Park, to the public on every Monday in July, August, and September at an admission fee of 1s.

**The Thames Embankment**.—"The Temple" writes to us: "Can any of your readers explain upon what principle of forestry the Plane trees of the Embankment, all along the river from Westminster to Waterloo Bridge, have just been shorn of half their beautiful fresh foliage? The work of stripping the trees and destroying their grateful shade rapidly approaches me, and I crave your protection, or, at least, some words of explanation from you."

**Lincoln's Inn Fields**, says the *Daily News*, should have a little more attention from the County Council. It is not in a good condition. The poor people of the adjacent slums for whose benefit it was bought have shown themselves only too sensible of their new privileges. But the Grass—as much of it as the sun of June has left us—is rapidly disappearing, and altogether the garden presents a most forlorn appearance. This is a pity for many reasons. Something should be done, and that speedily, to give everyone his rights in the place—the children who want their playground, the grown people, the aged and infirm who have an equal need of their quiet walk or lounge with a sight of the flowers. A writer in the *St. James's Gazette* says, and but too truly, that at present the children seem to have it all their own way, and that the garden is rapidly reverting to the state of nature. The position of the ground and the circumstances under which it was acquired are peculiar, and the County Council must take care that the garden does not become an awful warning against the policy of further acquisitions of the kind.

**Metropolitan Public Gardens Association**.—The Earl of Meath writes from 83, Lancaster Gate, under date June 21: "Bordering on the Thames at Putney is an old-fashioned house standing in an equally old-fashioned garden of about 2 acres, known as 'Riverbank' and containing some remarkably fine Elm trees, which form a prominent feature of the landscape, especially when viewed from the river and from Bishop's Park, Fulham, on the opposite shore. The property is now held under a lease expiring at Michaelmas, when the owners intend to place it in the builder's hands. The mansion is to be pulled down, a road is to be made through the garden, and the usual style of small villa residences will be run up on either side. Thus this shady riverside retreat will be wiped out of existence. Can nothing be done to save it? An open space adjoining the river is equal to one of ten times the size elsewhere. At the urgent entreaty of the Metropolitan Public Gardens Association the owners have agreed to stay their hands as regards arranging with builders until the end of this

month. Meanwhile they offer to sell us the entire property for £5100, or, as an alternative, the riverside portion only, about a quarter of an acre, for £1400. . . . The larger scheme, therefore, is by far the most attractive, as there would be no road, both the garden and the mansion would remain intact, and the latter would be available for public purposes, as at Ravenscourt, Clissold, and Waterloo Parks. I appeal to your readers to place the association in a position to secure this riverside property during the six short weeks that remain. . . . I shall be glad to receive donations, both large and small, towards the purchase of this site, which should be sent to 83, Lancaster Gate, London, W., crossed Coutts and Co., and I earnestly hope I may be fortunate enough to obtain a sum sufficient to buy the property before the end of next month. If unsuccessful, I shall, of course, return any money I may have received. One generous donor has already sent me £100."

**The weather in West Herts**.—In June the weather remained warm throughout the daytime and was on several occasions very hot, but on many nights the readings were below the average for the month. With the exception of the same month in 1893, the ground was warmer than in any of the previous nine Junes, and about 3° above the mean for that period. The most noteworthy feature of the past month was, however, the scanty rainfall, rain falling on only eight days, and to the aggregate depth of less than half an inch. The average fall of rain at Berkhamsted for June during the past thirty-nine years comes out as 2½ inches, so that the amount deposited last month fell short of the mean by nearly 2 inches. During those thirty-nine years there has been no June in which the rainfall has been as light. Taking May and June together we get a total of less than an inch; whereas a seasonable amount would be 4½ inches. Not a drop of water came through the 2½ feet of soil in either of the percolation gauges during the month. The atmosphere was, as a rule, calm and exceptionally dry. Besides being so dry, June was also an unusually sunny month; indeed, we have to go back to the Jubilee year in order to find a June in which the sun shone for as great a number of hours.—E. M., *Berkhamsted*.

**Variiegated Elder (W. M.)**.—The variegation is certainly of a distinct character, and decidedly pleasing if it remains constant. The Elder roots readily from cuttings. After the leaves have fallen make the shoot into cuttings and put them in firmly in a safe place where they will not be disturbed. Probably every one will grow the following spring.

**Royal Horticultural Society**.—The next meeting of the Royal Horticultural Society will be held in the Drill Hall, James St., Victoria St., on Tuesday, July 9, when a special show of Roses will be an attractive feature. At 3 o'clock Mr. Francis Darwin will deliver a lecture on "The Effects of Darkness on the Forms of Plants."

**Names of plants**.—*W. H. C.*—1, *Lychnis viscaria fl.-pl.*; 2, *Hieracium aurantiacum*; 3, *Betonica grandiflora*; 4, *Lychnis chalcidonica*; 5, *Veronica subsessilis longiflora*; 6, Spanish Iris.—*G. R. W.*—*Sidalcea candida*.—*Jas. Martin*.—*Cattleya gigas*.—*H. E. Dreewett*.—Pale form of *Cattleya Mossiae*.—*P. M.*—*Trachelium coeruleum*. An engraving of it appeared in *THE GARDEN* of April 27 of this year.—*E. M.*—*Lathyrus grandiflorus* and *L. azureus*.—*G. A. J.*—*Lobelia grandis tenebrosa*.—*Fero*.—*Lyimachia cleftroides*.—*Eustace P. Clark*.—1, *Geranium sanguineum var. lanceolatum*; 2, an ordinary form of *Masdevallia Veitchii*. May perhaps be better as the plant increases in vigour. The Campanula is not uncommon. *Streptocarpus* too shrivelled.—*Melway*.—*Cephalaria tatarica*.—*Cosmos*.—Rose Princess Louise Victoria.

**The Wild Garden**: or, the *Naturalisation and Natural Grouping of Hardy Exotic Plants*, with a chapter on the *Garden of British Wild Flowers*. Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. Demy 8vo, linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

No. 1224. SATURDAY, July 13, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## STOVE AND GREENHOUSE.

## MUTISIA DECURRENS.

ONCE went 200 miles to look at a plant of this, reputed to be grown under hardy conditions for some years in succession. I never regretted it, though I did not quite find all I had been led to expect. The plant chanced to be in bloom, and the big composite flowers were so grand that I made up my mind to grow the climber by any and all possible means I could command. What I saw was a plant some 7 feet to 9 feet high and as much across on an open wall (I think a west aspect), and the owner, the late Mr. Fraser, of Comely Bank, told me it was then getting worn out, that it had been there for some years. The plant, however, had been covered with mats in winter, but he doubted if the plant was any better for it. I believe it is the practice to grow this climber in cool greenhouses, but from what I saw and heard there cannot be room for much doubt as to its capabilities for standing out in the more favoured climate of Ireland, the south of England, and some places in the west. At present the plant is in flower with me in a cool greenhouse, and though there are some tempting Water Lilies in tubs near to it in bloom, the glorious flowers of this climber draw first attention. The big Daisy-shaped flowers are each 4 inches across when fully expanded, the points of the ray florets more or less recurved. The colour is even deeper orange than the rich hue of the darkest bitter Seville Orange, there is more scarlet in it, and the shiny character adds brilliancy to the effect. These flowers are produced singly at the points of the new growths, and though not very numerous, the plant keeps gay by reason of the long time the flowers last individually and follow on in succession. The foliage is singular, as implied by the name decurrent, and that to such an extent as to impart a much-winged effect to the stems. Tendrils, long and very wiry, develop from the apex of the leaves, by means of which the plant fastens itself to any suitable medium. So characteristic is the plant, and so very effective are the flowers, that I am sure were the plant tried in some of our most favoured districts it could not fail to reward its cultivator. I feel sure from what I saw that it could be grown in such places out of doors, though I cannot hope to so grow it in Yorkshire.

Woodville, Kirkstall.

J. Wood.

**Medinilla magnifica.**—Few indoor shrubs are as showy as this—that is, when it is in full flower, which is in many places the case at the present time. It is a bold growing bush, clothed with handsome foliage, while the large racemes of blossoms, which are borne on the point of every branch, are pendulous, thus adding additional grace to the plant. The blossoms and the bracts which accompany them, as well as the flower-stems, are bright pink. An additional feature is that the flowers remain fresh a considerable time. When large specimen plants were more in vogue than they are at the present day this *Medinilla* was very popular, as it formed a very imposing plant when well flowered. It is a native of the Philippine Islands, and was introduced therefrom in 1848. It needs copious sup-

plies of water during the growing season, but of course less is needed when at rest, for a good deal of the future display of bloom depends upon the thorough ripening of the wood, which is carried out by full exposure to the sunshine, and by giving less water than when growing, but at no time must the plants be allowed to suffer from want of water. This is by far the showiest member of the genus, but a very pretty shrub is *M. amabilis*, in which the panicles of blossoms are upright instead of drooping, thus presenting a totally different appearance. The little *M. Curtisi*, with panicles of white blossoms, is also a pretty shrub, and may be grown in less space than is needed for the other two.—H. P.

**Pelargonium Miss Louisa Coombs.**—In the notice of a few select show Pelargoniums in flower at Mr. Turner's nursery on p. 445 last volume I did not see any mention of the new variety Miss Louisa Coombs, which was, I believe, sent out by Mr. Turner in the spring of the present year. It is of a good, freely-branched habit with ample foliage and very large trusses of flowers. The individual blooms, too, are large and bold. The flowers of this are round, the upper petals maroon, surrounded with bright crimson and edged with rose, while the lower ones are bright rose, the basal portion white, thus forming a white centre to the flower. The edges of the petals are rather undulated, thereby showing a break away from the smooth, unbroken edge of the show varieties. It is undoubtedly a good decorative kind, and partakes more of the character of some of those which are so popular for market work. The feature that militates against these high-class show varieties for general decoration is that it is difficult to get a small plant in a 5-inch pot well furnished to the base, and though the individual blooms are remarkably telling, the trusses are very small, and the plants therefore do not present such masses of bloom as the popular market kinds. Such an objection cannot, however, be urged against this variety.—H. P.

**Cobæa scandens variegata.**—For houses of tolerably large dimensions this is a very useful climber. It quickly grows into a large specimen, and the effect of a mass of its variegated foliage is very good. It is one of those things that can live healthily and even extend in a root-bound condition. I have seen plants of it running up 20 feet high and covering some square yards with perfect leafage in a 12-inch pot. One great point in its favour is freedom from insect pests, which are generally troublesome to greenhouse climbers.—J. C. B.

**Hydrangea Thomas Hogg.**—As stated by "R. D.," *Hydrangea Thomas Hogg* is a noble plant when grown as a large specimen. Some years ago I grew such an one as that described by "R. D.," there being exactly 100 trusses. They were thinned down to this number so as to gain size in the individual trusses. This variety will produce a flowering truss from almost every bud when well ripened. In the formation of large plants the annual growth must be encouraged to form in the full sun. Being wintered in a cool house, these shoots of ripened wood should be tied around the flower-stakes, so as to form the foundation of the future specimen. Neat little plants are formed by inserting cuttings now, or later on in the autumn, after the embryo truss has formed. As soon as rooted the plants must be grown in the full sun in the open air, after being repotted and established in 5-inch pots. I generally place three cuttings in a pot. These, when repotted into 6-inch pots, form nice plants with three heads of bloom.—A. YOUNG.

**Crotona in small pots.**—One advantage attending the culture of these fine-leaved plants is that they may be grown to comparatively large dimensions in small pots. This is of value in the case of plants that are employed for room decoration and that have to be placed in vases, jardinières, &c. Crotons are among the most free-growing of warm house plants, only requiring a high temperature with abundant atmospheric

moisture to induce a healthy leaf development. They demand more warmth and atmospheric moisture than *Dracenas* and the usual run of warm house fine-leaved things. This is probably the reason why they are not so largely grown as would otherwise be the case. When there is suitable accommodation, however, and neat, bushy, bright-looking plants in small pots are required for room and table decoration, Crotons should be well cared for. We have nothing quite like them among ornamental-leaved plants.—J. C. B.

## NOTES FROM HIGHBURY.

ORCHIDS are so largely associated with the name of Highbury and the popular owner, the Right Hon. Joseph Chamberlain, that other phases of gardening often go unnoticed, but because Orchids predominate so largely it must not be understood that general gardening is not given much attention. Plants other than Orchids are largely grown, but instead of endeavouring to fill the houses with numberless species and varieties of plants, large patches of a few kinds, according to season, are grown so as to make each house effective in itself. For instance, there was at the time of my visit one house filled with a splendid batch of *Gloxinias* in full flower, another was entirely devoted to Pelargoniums, a third to tuberous Begonias, and this same principle is apparent throughout the many houses to be seen. What may be termed the show houses at Highbury are connected by a very long corridor, Orchids, fine-foliaged and flowering plants alternating so as to render them interesting. These houses are replenished from others outside, as well as pits and frames, so as to keep them always gay. Anthuriums, *Amarylids*, and *Clivias* Mr. Chamberlain takes a great interest in, hybridising and seed-raising being closely watched by him throughout the year.

Tea-scented and Hybrid Perpetual Roses are a strong feature, and are well grown both in pots and planted out. The American principle of planting them in shallow beds thickly indoors is under trial, cuttings being rooted and grown on for the purpose, while some are already planted and giving promise of a good return. There is such a demand for cut blooms of these, that sufficient has to be grown in pots to furnish them from the autumn until they can be gathered outdoors, and judging from the quantities standing outside as I saw them, there should be no difficulty in doing so. *Chrysanthemums*, both for large flowers and decorative bush plants, are represented in large numbers, and their present state bespeaks a very fine display in due course. Large batches of *Cyclamens* and *Primulas* were being forwarded in cool pits for early winter flowering, and were already large and enviably luxuriant plants, the *Cyclamens* being half plunged in cocoa-nut fibre.

In the spacious conservatory attached to the house there towers in the central bed a lofty *Chamerops* excelsa in fine health and vigour, smaller but vigorous *Areca*s forming the central plants in smaller groups. The rockwork fernery adjoining is equally interesting, Ferns, Mosses, Palms and other plants revelling in the moist recesses. In this house *Anthurium Chamberlainianum* is a striking plant. The corridor itself is at all times bright with flowering dwarf and climbing plants growing in the side borders. Here the large specimen Orchids are displayed to their fullest advantage. *Sobralias* at the time of my visit were magnificent both in the size of plant and quality and quantity of the blooms expanded.

Among the Orchids one of the most noteworthy plants in the collection was *Dendrobium thyrsiflorum*, which I was told this year carried no less than seventy of its delicate racemes. I have never before seen such strong spikes and vigorous plants of *Epidendrum vitellinum* or such freely flowered *Masdevallias* in several varieties as here.

Fruit culture is not so extensively carried out as plant and flower growing, but the best is made of the space devoted to it, and good crops are obtained.

The vegetable garden not being very extensive, the most has to be made of it by close cropping, as the demands from the kitchen are heavy. In the pleasure grounds shrubs and trees have been freely planted in clumps, and this is being carried on round the park boundaries, so as to add colour to the distant landscape. Rhododendrons are a fine show in their season, as these are planted in bold masses. The borders are everywhere filled with flowers, so that in spring the grounds are bright with endless varieties and colours. In some spots, too, they have been thickly planted in the turf with good effect.

At night the conservatories and corridor are all brightly illuminated by electric light, so that visitors are not confined to the house after night-fall, but can inspect the hosts of Orchids and other plants better even than by day, and this without going outdoors.

VISITOR.

### BEGONIAS AT FOREST HILL.

So great are the advances that have been made in the tuberous Begonia within the last decade, that if the most recent kinds were shown beside even the best of those in cultivation ten years ago, some might feel disposed to doubt that so much had been accomplished in so short a time. There are now many growers who make a specialty of this flower, but none have worked longer among them or done more to raise them to their present state of excellence than Messrs. Laing, of Forest Hill. The present display at the Forest Hill nurseries is a grand one, several large houses being entirely filled with fine kinds embracing a wide range of colour in both single and double-flowered varieties. The older forms needed sticks to support the shoots, and the drooping flowers were often half hidden among the leaves, but the best Begonias of to-day are a marked contrast. The development of the flower has not been at the expense of the plant and its constitution, but the possession of a robust habit has been rightly considered as essential as size and distinctness of bloom. Thus we see to-day the finest flowers upon plants with stout self-supporting growth, the shoots short-jointed, the leafage large and luxuriant, and the flowers all disposed so that they can be seen to the best advantage. This applies not merely to the single kinds, but to the double-flowered varieties as well, which by reason of the greater size and weight of their blooms were even more disposed to hang down. Yet without undue shortening of the flower-stem these too have acquired a robustness that enables them to hold up their flowers boldly, and this is a marked characteristic not in a few kinds only, but in the majority of those grown.

The single varieties of the present time have flowers of such great size that any further increase is hardly desired, but new and distinct variations of another character would be welcome and sustain the interest in these flowers. The round form and perfectly regular outline so dear to florists of the old school become monotonous. A distinct break away from this form of flower is seen in a new variety now flowering, and which we hope will have its counterpart in many colours. It has been named *Duchess of Fife*. It is a lovely kind combining graceful form with fine size and delicate colour. The flowers are rosy-pink, the edges of the petals beautifully and regularly undulated, a most distinct outline which adds to the beauty of the flower. The form of this variety is quite different from that of another rather pretty variation that has lately appeared, namely, a fringed edge to the petals. Laing's *Fringed White* is the finest of this type, a pure and pretty flower; *Grand Duchess of Hesse* is a fine kind with large pure white flowers; *Mrs. Benson* is of a rosy-salmon shade and pretty

form, the petals slightly crimped at their edge; *Sunlight* has large flowers that are white in the centre, the edge a bright rosy-cerise; and *Countess of Brownlow* is of a distinct bronzy-orange shade, a rich and telling colour; *Britannia*, orange buff; *Lord Brassey*, cerise-red; *John Roberts*, deep rose; *Marchioness of Salisbury*, yellow, very good and the largest in its colour, were all conspicuous. *Lady Esther Smith* has a white centre edged with rose, and *Lady Farquhar* is a lovely shade of pink, very free flowering. *Lady Wantage*, pure rose, and the *Hon. Mrs. Reid*, blush-pink, free and fine, must be mentioned; whilst the *Duke of Richmond* and *Gordon*, dark crimson, and *Colonel Henderson*, of a brighter crimson-scarlet hue, are two noble red kinds. These are a select few of the newest and best single varieties, but many besides were seen well deserving of mention did space permit. The

### DOUBLE-FLOWERED KINDS

vary greatly in form and colour, the flowers of some varieties being Camellia-shaped, with broad, flat, over-lapping petals, others thick rosettes with outer guard petals, but the majority of those we saw were erect and self-supporting. Among the newest kinds we noted *Duchess of Northumberland*, with fine bright salmon-coloured flowers; *Duchess of York*, orange-yellow, the broad petals flushed with soft pink on their edges, free and robust in habit; *Prince Adolphus of Teck*, deep crimson-scarlet, with a flat-petalled Camellia-like flower, and which received an award of merit at the Drill Hall recently; and *Dowager Lady Williams Wynn*, of similar shape, erect habit, and rich deep yellow in colour. Laing's *Rosebud* is a distinctly pretty kind of a blush-pink colour, as refined and choice as a Tea Rose; whilst *Countess of Craven*, double white, a perfect snowball; *Countess of Warwick*, salmon-scarlet, large and fine; and *Lady Theodora Guest*, a distinct shade of apricot-yellow, with prettily fringed petals, are all good. *Duke of Fife* is a free variety, with large rosy salmon flowers; *Lady Dunsany*, a charming pink flower; *Lady Willmot*, light salmon; and *W. Clifford*, a Camellia-shaped, deep rose kind. *Invincible* is one of the best bright crimsons that has been raised, whilst the biggest flower is seen in Laing's *Triumph*, which is deep rose. *Majestic*, rose; *F. W. Soames*, scarlet; *Marchioness of Downshire*, dark crimson; *Mrs. Stoddart* and *Mrs. Reguart*, both yellow, and *W. A. Richardson*, which in colour much resembles the Rose of that name, are all new or recent additions of great merit and beauty.

*Clitoria ternatea*.—This stove climber was introduced quite early in the last century, yet some five years ago when a coloured plate of it was published in THE GARDEN it was recognised by very few, for, beautiful as the blossoms are, it was almost unknown outside of botanic gardens. One of the exceptions was at Syon House, where Mr. Wythes grew the specimens from which the coloured plate in question was prepared. This *Clitoria* is a native of the Malayan Archipelago, but it is now generally distributed in many parts of the tropics, where, rambling over bushes or festooning any support within reach, it forms a charming picture. Seeds can be obtained at a cheap rate from most dealers in such things, and if sown in the spring they will grow freely and flower throughout the summer, or frequently well on into the autumn. As a rafter plant for a small stove or for supplying a screen at the end of a glass structure, this *Clitoria* is well suited. Care must be taken not to overpot it, and frequent syringings are necessary in order to keep the foliage free of red spider, which soon disfigures the leaves. Even though the pots may be rather

small, the plants must not be allowed to become stunted, and in order to prevent this as far as possible, they should be liberally supplied with manure water, taking care that it is not too strong, as it is better to use stimulants weak and often than in too concentrated a form. The intense rich indigo-blue of the flowers is most striking. Seedlings vary considerably, but the best forms can be increased by cuttings. There are, however, several well-marked varieties, the flowers differing greatly in colour, for not only are many shades of blue to be found among them, but there is also a form with white blossoms, and another in which the flowers are semi-double. There are several other species of *Clitoria*, but none of them are in general cultivation.—H. P.

*Impatiensauricoma*.—This species of Balsam, which was recently introduced from Madagascar and distributed last year, has proved to be most continuous flowering, for the golden-yellow blossoms with a flush of crimson in the centre are borne for a lengthened period. It is also a free, yet sturdy habit of growth and may already be met with in many gardens. As a garden plant this newer introduction is considerably inferior to the popular *Impatiens Sultani*, and the individual blooms are also less showy than those of *I. Hawkeri*, but still, by a judicious selection of seedlings, it may yet be considerably improved. As might be supposed from being a native of Madagascar, it requires stove treatment in this country, though during the summer it will succeed in an intermediate house. *I. Hawkeri*, of which great things were expected, has never attained the popularity that was predicted for it when new, as it cannot be depended upon to bloom freely, especially in a small state, and the young leaves are very liable to be attacked by a minute form of thrips, which soon injure the plant. *I. Hawkeri*, as far as I know, has not produced seed in this country.—H. P.

### STEPHANOTIS LEAVES TURNING YELLOW.

I WILL be much obliged if the editor will tell me the reason of the enclosed leaves of my *Stephanotis* turning yellow. It is a large plant and stretches nearly the whole length of a small stove. It is about four years old and has always been very healthy. At the present moment it is full of flower, but the leaves are gradually becoming yellow, and, though the young shoots look healthy, the blossoms forming on them drop off. It is planted out.—M. M.

\* \* The leaves of the *Stephanotis* in question have been examined very closely, but no trace of disease can be detected thereon. Several reasons might be given which would tend to cause the leaves to turn yellow and drop off prematurely. Being planted out, the condition of the border would give rise to it; either the extreme of excessive moisture, or that of drought, would cause it. Is the plant dry under the surface whilst to all appearance moist to the outward eye? If so, that would cause the leaves to drop. Possibly the soil is in a measure impoverished. That too would produce the same effect. If the drainage be not good, the roots would get sickly and the same results follow. Indifferent soil would tend to the same end. The *Stephanotis* thrives best in about equal parts of good loam and peat, with plenty of sand, which should be made quite firm. The application of an excessive amount of an artificial manure in itself would be sufficient to cause the same ill-effects; weak doses at fairly good intervals during growth would do no harm (say once a week). A low temperature during the past severe winter would cause the *Stephanotis* to cast its foliage, but if this were the cause it should have happened sooner; lower than 50° is never desirable. Too much exposure to chilling winds, or to the extreme of sunshine after dull weather, would be injurious. The foliage sent did not show any trace of insect pests, being, on the other hand, unusually clean; this, therefore, could scarcely be the cause, unless

a strong dose of any insecticide had been applied or severe sponging been resorted to. Whilst growing, a night temperature of from 65° to 70° at this season would suit this plant well, the syringe being freely employed at least once every day. Should the same thing continue, the stem should be closely examined; an injury thereon might have taken place which is not thus far detected. A rather hard pruning given now would possibly result in a late summer growth, which would flower early next spring. If this were done, a good top-dressing of fresh soil after the removal of any that may be sour or inert would help to renovate the plant.—GROWER.

### LILIES FOR MARKET.

DURING the last few years the culture of Lilies for profit has much increased. The most valuable of the family for this purpose are undoubtedly longiflorum and its Bermuda form, Harrisi, and the old white Madonna Lily of cottage gardens. The suitability of the last-mentioned for culture under glass does not seem to have been known to the older generation of gardeners, and probably its merits in this respect might still be unknown were it not for the attention that has been given of late to the other pure white kinds. Of longiflorum it is impossible to speak too highly, and those who took up its culture extensively a few years ago made handsome profits. Like all things grown for the London markets, however, prices through competition have been lowered, but fine blooms of this fair flower still make tolerably good prices, especially in May and early June. I have never seen anything finer than the long houses in some of the London market gardens crowded with plants of this Lily carrying thousands of blooms, their purity enhanced by the deep lustrous green which characterises the foliage when the plants are well grown. L. Harrisi is very valuable on account of its early blooming nature, which enables market growers to obtain a supply of blooms quite early in the season and when higher prices can be made. This Lily was to have bloomed twice in the season, but the second crop of flowers is too scanty and too late to be of much value, and the bulbs do not retain this perpetual blooming character in this country. I know of one London grower who worked up a large stock of plants from scales, but when they came to flowering size the blooms did not differ to any great extent from those of the old longiflorum either in form or manner and time of opening. Therefore those who wish to secure a crop of very early blooms would be wise to procure good imported bulbs as soon as they come to hand. Those who supply the London markets lose no time in potting the bulbs. They are generally grown two or three bulbs in a 7-inch pot, the compost consisting of good turfy loam, space being allowed for top-dressing later on. The old white Lily has to be potted during its short resting period. Early in autumn the young leaves appear, and before that time the roots should be working in the new compost. It is found, however, that the best results are obtained from bulbs that have been a year undisturbed. They start with greater freedom, and the flower-spikes are stronger than in the case of bulbs that have remained some weeks out of the soil. This Lily will take liberal doses of liquid manure when in full growth; indeed, in the case of plants that are grown for cut blooms and that have filled the compost with active fibres, liberal feeding is absolutely necessary. I have known bulbs to remain undisturbed without change of soil for several years and annually yield a profitable crop of flowers. One advantage of growing them in this way is that they do not get the disease that works so much havoc in the open air. The flowers are utilised in various ways, some being cut as they expand, these being employed for wreaths, crosses, &c. For other floral decorations, and especially for churches, the whole stem is cut, while a great many plants are sold in the pots. J. C. B.

### NOTES OF THE WEEK.

**Prunella grandiflora** is a good variety that quite bears out the name, for its flowers are very fine at Kew, where a little group looks pretty in the rock garden. The flowers, borne in a long, thick head, are of a rose colour with purple bracts.

**Gladiolus dracocephalus**, a Cape species from Natal, is now flowering at Kew. It has tall spikes about 5 feet in height; these bear many flowers of a bronzy yellow colour, curiously mottled and spotted inside and out with a dull red. It is a very distinct species, of graceful aspect, but needs close inspection to see its quaint colour.

**Bravoa geminiflora** is a pretty Mexican bulb now flowering at Kew in a frame. It has slender scapes, each about 2 feet in height, these bearing numbers of long drooping bells of a distinct coral-red colour. It is a free-blooming plant under congenial conditions, as there are nearly two dozen spikes of flowers from one little clump of bulbs.

The common **Chicory** is rarely seen in the garden, and yet we know of no lovelier hardy flower. It is worthy of a little trouble to naturalise it, especially as once this is accomplished it will take care of itself. The other day we stood beside a magnificent plant that was over 6 feet high, and the hundreds of lovely blue blossoms freshly expanded and glowing in the morning sun had a fine effect.

**Scabiosa caucasica** is one of the very best hardy flowers in a soil that suits it, blooming continuously for months. On several occasions during the past few weeks we have noticed a splendid plant of it in the herbaceous ground at Kew, showing that a light free soil is essential to its well-doing. The flowers of the Kew plant are very fine. Both this and its lovely white form are very effective where they do well.

**Oenothera speciosa**.—This is a neglected plant of great beauty, truly perennial and blooming abundantly over a long period. It seems very happy in this season of sunshine, as even in the light soil at Kew a mass of it is covered with flowers. Their effect is charming in the bright sun, as they are almost transparent and of the purest white, shading prettily into cream at their base. It grows little more than a foot high, and makes a beautiful group.

**Lilium Grayi**.—This new and beautiful Lily has been flowering well at Kew, some of the strongest shoots being about 4 feet high and bearing seven of the handsome flowers. It is allied to *L. canadense*, having similar drooping bell-shaped flowers in whorls, but the flowers are smaller, less expanded, and but slightly reflexed at the tips of the petals. They are of a deep rich crimson-red colour, profusely spotted inside with purple-brown.

**Laurus nobilis as a tree**.—Though everyone who knows anything about trees and shrubs will at once recognise that I am writing about the Bay tree, can anyone send you, as I do now, a photograph of it in tree form? We all know it as a bush, but I cannot remember to have ever seen it before as a tree. It is growing in this village. The garden in which it is growing is close to a road. The plant is about 26 feet high.—W. T., Bishopsteignton.

**Lathyrus tuberosus** is an uncommon perennial Pea, which in colour resembles *L. latifolius*. It is equally free-flowering, but has smaller blooms and thinner growth. There is a group of it in the herbaceous grounds at Kew, and at Knap Hill recently we saw a lot of it that springs up annually among the stones of a paved pathway and flowers as well as if it were under cultivation. It could easily be naturalised in a pretty way.

**Verbascum Chaixi**.—It is curious how some of the finest garden flowers are neglected and only seen in a few places. This noble perennial Mul-

lein has been in the country long enough for everyone to have it if they wished to, and yet it is the exception to meet with it. In the rock garden at Kew and in the herbaceous grounds there are some splendid plants now in flower, the finest of them over 6 feet in height, quite half of the plant a perfect column adorned with myriads of blossoms.

**Hymenocallis (Ismene) Amancaes**.—A clump of this is now flowering well at Kew in the frame devoted to half-hardy bulbs. It is a very handsome Peruvian plant allied to and resembling the *Paneratiums*. There are four strong flower-scapes rising out of a mass of large deep green leaves, each bearing several blooms which open in succession. They are larger in the tube and have broader petals than those of the *Paneratium*, of a rich cream colour when first open, passing to white, whilst they have a delightful scent.

**Senecio macrophyllus**.—This giant Groundsel is a striking plant, and a mass of it at Kew arrests attention both by the luxuriance of leaf growth and the bright effect of the tall spikes of flowers. To grow in groups along with other strong herbaceous plants, such as the *Inulas*, *Telekias* and *Sunflowers*, it well deserves attention. Its immense broad spatulate leaves are each nearly a yard long, and the flower-spikes rise erect to 6 feet, the upper portion a dense club like mass of bright yellow flowers.

**Magnolia glauca**, which we recently noted as flowering at Knap Hill, is also in bloom at Kew, where two flourishing specimens may be seen isolated on the Grass. In the bright sunshine they are seen to advantage, with the strong light reflected from their polished leaves, a gentle breeze displaying their silvery under surfaces. Although the flowers are not so large and showy as those of the earlier kinds, they are very pretty and their delicious fragrance is quite perceptible in the air around the plants.

The **Kentish Strawberry crop** has been extraordinarily heavy, and the picking is still at its height. Reports from the Maidstone, Sandwich and Swanley districts agree that the crop is about double the average. From Sandwich alone upwards of 100 tons were despatched last week. There is a great increase in the acreage under Strawberries this year as compared with last, and cultivation is increasing in a remarkable way. The satisfactory feature is that their cultivation is likely to be paying to the farmer, as the demand for the fruit increases also.

**Robinia Pseudacacia semperflorens**.—The False Acacia in its several forms is a beautiful tree, and one of the best of them is the variety which bears the above name. At present few seem to plant it, and doubts have been expressed as to the constancy of this characteristic, but it is maintained. Long after all other False Acacias have ceased flowering this one continues producing a raceme of flowers at every joint of the growing shoots. In Mr. Waterer's nursery we noticed that even young trees were flowering apparently at an earlier age than those of the type itself.

**Coreopsis (Leptosyne) maritima** is a handsome annual species, which we noted at Kew. The genus *Leptosyne* is now included under *Coreopsis*, and embraces the Western American representatives of the *Coreopsis* family. This under notice is a Californian kind and apparently an annual worthy of more attention. The plant grows about 1 foot high, its leaves being finely cut into numerous grass-like segments. The flowers, entirely yellow both in the disc and rays, which number about twenty, are as large as those of *Chrysanthemum maximum* and borne singly on strong stalks over a foot in length, so that they are well adapted for cutting.

**Lilium Lowi and L. Bakerianum**.—These two Burmese Lilies are now flowering in Mr. Ware's nursery at Tottenham. *L. Lowi* is of recent introduction and a charming addition to the Lily family. It has drooping, funnel-shaped white flowers, the tips of the segments reflexing, the inner part of the tube abundantly spotted

with purple. A coloured plate of this Lily appeared in THE GARDEN of March 17, 1894. *L. Bakerianum*, although not exactly new, is rare in cultivation. It is apparently nearly allied to *L. Lowi*, but the flowers we saw were even more spotted inside, and a band of a distinct rosy shade runs down the centre of the petals externally.

**Genista ætensis.**—This graceful south European Broom appears to have stood the past winter very well, and large spreading bushes of it nearly 12 feet high and laden with flowers are effective in some of the shrub groups at Kew. It might be called a miniature Spanish Broom, not as regards stature, but it has Rush-like twigs like the *Spartium*, only they are much more slender, and the rich yellow flowers, though smaller, more than make up in effect for what they lack in size. As a shrub for light, hot soils much might be said in its favour. One only needs to see it as at Kew to be at once favourably impressed with its beauty. A coloured plate, which shows well its beauty and free blooming character, appeared in THE GARDEN of March 18, 1893.

**Rosa polyantha** is now, and has been for the last fortnight, a pretty feature. In any aspect it looks happy, whether on dry or moist banks. Growing against low trees, sending its long shoots, covered with innumerable heads of white bloom and the richest of green foliage, up into their branches and arching over to the ground, the effect is very fine. On the banks of the lake, too, the snowy branches touching the water, with the reflection below it, is very beautiful. For any open space in the shrubbery, for covering a fence, or forming banks to shelter tender subjects, it is one of the best wild Roses. All that it requires is to have plenty of room to develop and show its graceful character and to be left alone.—M. J.

**Lælia elegans** (Woodlands variety).—This superb variety is now in bloom in the Woodlands collection of Mr. Measures. *Lælia* is a special feature here, as Orchid growers well know, and this variety is one of the most beautiful of all the forms of *L. elegans*. A distinctive point is that the two upper lobes of the lip are of abnormally large size, the sepals and petals being French white and quite glistening in aspect, while the margin of the former is without any undulation, unlike the petals. The lip is unique for boldness and rich crimson in colour, which extends over the whole of the outer surface of the upper lobes, running in a band down to the ovary, the remaining portion being white on both surfaces. It is delicately fringed, also heavily fluted. The column is large and rosy pink in colour.

**Lilium odorum.**—This noble Lily is now flowering grandly at Kew. There are two round beds of it behind the Palm house, and visitors to Kew within the next week should make a point of seeing it. The plants are healthy and robust, the strong stems terminated by, in most cases, two immense flowers disposed opposite to each other. They are quite as beautiful as those of the popular *L. auratum*, without the overpowering odour of that species. They are sweetly fragrant. The tube of the flower is of the purest creamy white, without spot or stain, but the exterior of the flower is stained with a deep chocolate hue. We noticed two immense flowers caused by the fusion of two blooms on one stem. They retain their single form, but have double the usual number of petals and anthers, and two stigmas also. It is a most striking and handsome Lily.

**Gunton Park, Lord Suffield, and Waterloo Strawberries.**—I herewith send you a few fruits of the above-named Strawberries. I consider Gunton Park the best all-round variety in cultivation. Lord Suffield is a little later in ripening and forms a good succession. It is a capital cropper, the fruit being of exceptionally rich flavour and of a very dark mahogany colour. These, coupled with *Empress of India*, form the most valuable Strawberry trio introduced of recent years. Waterloo is most useful where it

succeeds, but it is somewhat capricious and never makes large plants. It does well on our rather light soil, well mulched in autumn. One of its best points is its non-liability to rot in rainy weather. If grown in porous soil on a north border it is useful for late work. I consider its flavour pretty good and the colour is very taking.—J. CRAWFORD, *Coddington Hall, Newark.*

**Brodiaëas at Colchester.**—Among the choice and little-grown bulbs that merit more popularity are these. They are grown well in Messrs. Wallace's nursery at Colchester. Some of the earlier species were over at the time of our visit, but two or three distinct varieties were still fresh and abundant. *B. peduncularis* was one, and is most graceful. It has a large umbel of flowers borne on an erect stem, each flower on a long slender stalk, making the heads quite 1 foot in diameter. The flowers almost exactly resembling those of *Triteleia uniflora* are white, with a distinct violet line down the centre of the petals outside; a mass of it is most elegant. *B. rosea* is a new species of quite a distinct shade, having a neat umbel of light pink flowers on a dwarf erect stem. The old *B. volubilis* is quite a unique twining plant, that reverses the usual order of things in having climbing flower-stems, which, entwined around Bamboo canes, were here quite 5 feet in length and terminated by large umbels of beautiful deep rose-coloured flowers.

**Hemerocallis aurantiaca.**—This is a very notable addition to our hardy garden flowers and merited the first-class certificate that was granted to it at the meeting last Tuesday. It was shown by Messrs. R. Wallace and Co., of Colchester, who have introduced many good flowers, but certainly none finer than this, because it is a plant that everybody can grow and we feel sure will want to have when it is distributed. All the Day Lilies are characterised by robustness, and this essential merit is accentuated in the variety under notice. In appearance, vigorous growth and form of flower it partakes most of the character of *H. disticha*, and we might almost hazard an opinion that it is a deep golden seedling of this species. It originated in Japan, where it was first noticed growing in a mass of *Iris Kämpferi*. Its leaves are broad and slightly glaucous, the flowers numerous on a very strong scape, and of extra stout substance, the petals being quite fleshy. It most resembles *H. disticha* in its large, widely expanded flower, the broad petals distinctly recurved at their tips, but in its rich shade of apricot-yellow it stands out conspicuously as a most distinct, beautiful, and highly coloured form.

**Lilium giganteum.**—This fine Lily is flowering now in the Bamboo garden at Kew. It is 8 feet high and bears about a dozen blooms, the stem being a couple of inches in diameter near the ground. A native of the Himalayas, and introduced over forty years ago, it has never become very common in cultivation. This is owing to its not succeeding well in many parts of the country and to the bulb dying after it has flowered once. The flowers are about 8 inches long and 4 inches to 5 inches across the slightly recurved segments. They are white inside, tinged with reddish purple, and greenish yellow on the outside. The large cordate leaves are a feature in themselves, those at the base having a blade 15 inches in length, and borne on a petiole nearly as long. These large leaf-stalks are one of the most distinguishing features of this Lily; in fact, the leaves differ from those of all other Lilies not only in this character, but in their size, shape, and reticulated venation. On the stems of flowering plants they become smaller towards the top until they are finally reduced to mere bracts. The noble habit of the plant with its imposing crown of flowers makes one wish it were to be seen oftener. It should be planted in a rich loam and be mulched during the summer. The only other Lily closely related to this is *L. cordifolium*, a Japanese species or, according to some authorities, a variety of *giganteum*. It is a smaller plant, and of not the same value horticulturally.

## FERNS.

### RAISING FERNS FROM SEED.

IN reply to "W. H. M.," Warrington, the most natural as also the quickest way of propagating Ferns is by means of their spores or seeds. These should be gathered when the capsules containing them begin to assume a brownish colour; the fronds should then be cut, put into paper bags and allowed to dry for two or three days, after which time the spores should be sown as soon as possible, although most of them retain their vitality for a considerable time. Although Ferns may be sown at any season of the year, the early spring is the most favourable time, as if properly treated, seedlings, or the generality of them, raised then have sufficient time to produce crowns strong enough to stand the following winter. Many ingenious ways of sowing Fern spores have been recommended, such as sowing on prepared flannel, &c., but, provided the materials used be of pure quality, either a piece of turfy loam, a piece of fibrous peat, or sometimes a mixture of both roughly broken and perfectly free from decomposition of organic matter is all that is required. An excellent way of getting rid of vegetable or animal life in the material used for sowing consists in gently pouring the contents of a kettleful of boiling water over it. When the soil thus treated has been allowed to cool and drain it is ready for use, as eggs or larvae of insects, spores of fungi, &c., are or should be all destroyed. The Fern spores which are exceedingly minute must be scattered on the surface of the prepared soil and covered with either a bell-glass or a sheet of glass and kept in a close shady place under a handlight if possible, but this is not absolutely necessary. There they should remain until the surface of the pots or pans which contain them becomes covered with a growth of Lichen or Liverwort appearance. From this singular growth the young Ferns ultimately develop, according to the different species, in a space of time usually varying from three to six months from the time of sowing. During that time the pots or pans in which the spores are sown should be kept in a uniform state of moisture, the watering should be done by partial immersion by standing the pots or pans in water for a few inches, so that the moisture rises to the surface. When Fern spores germinate freely, it is necessary that they should be several times divided, for if allowed to crowd and overgrow each other in the seed pan or pot they are very liable to damp off. They should still be watered by partial immersion and no water should be applied overhead until they have produced fronds. They should be gradually inured to the air by tilting on one side the glass cover, which may in a short time be removed altogether. Until then it is best to keep the pots or pans at all times well shaded during sunshine, but not in dull weather. When fronds have made their appearance, the seedlings do not require any other shading than that to which the house is usually subjected. When the seedlings have formed a little crown and are provided with two or three fronds, they should be potted singly or placed in pans or boxes and kept for a time in a somewhat close atmosphere, well shaded and carefully watered until established. Greenhouse and stove Ferns require to be sown in a warm house; whereas for British and hardy exotic kinds a damp, shady, but not dark corner under the stage of a greenhouse or cold frame is all that is required. S. G.

ORCHARD AND FRUIT GARDEN.

WHITE BLACKBERRY ICEBERG.

THIS new Blackberry was raised by Mr. L. Burbank, of Santa Rosa, California, by crossing a variety named the Old Crystal White with Lawton, which in America is considered the most productive Blackberry known. The berries of Iceberg, as may be seen from the engraving herewith, are large and freely produced. They are said to be delicious in flavour and so transparent, that the seeds, which are

easily mastered, is its obstinacy in colouring to the point. In Empress of India, one of Mr. Allen's new seedlings, however, this difficulty is overcome, as it colours well throughout, and is, moreover, quite equal to, and, in the opinion of some, superior to British Queen. All who esteem high-class quality should grow Empress of India. —J. C.

**Summer-pruning fruit trees.**—Mr. Iggulden's interesting notes on mutilating fruit trees remind me of the fact that even those who use the knife in a practical manner often summer-prune their wall trees far too soon. For the sake of neatness they cut back all breast wood perhaps

White Blackberry Iceberg. Engraved for THE GARDEN from a photograph sent by Mr. Luther Burbank, Santa Rosa, California.

remarkably small, may be seen in the berries when ripe. The clusters of fruit are said to be very large and as firm of those of Lawton. We understand that this variety will be put into commerce by Messrs. Pitcher and Manda, of Short Hills, New Jersey.

**Strawberry British Queen.**—In Mr. McIndoe's fine collection of ten dishes of fruit at York was a good dish of British Queen. Strawberry grown in pots, and, of course, quite cool. It was quite a treat to see this old kind in good form, as one so seldom meets with it now-a-days. Mr. McIndoe informed me that he had grown it in pots for late work for many years. The one fault with British Queen, and one which seems not to be

by the middle of June; consequently another free growth follows, the back eyes breaking into growth also on account of being so soft and green. No wonder then that their trees are poorly furnished with fruitful spurs and remain comparatively barren. Late summer pruning is, of course, more necessary in midland and northern localities, but I am convinced from personal observation that even in the southern counties the work is done in very many instances far too early. I myself do not take off the wood until July is getting well advanced. —J. CRAWFORD.

**Strawberry Royal Sovereign.**—I am glad to see that "W." (p. 463) is of one mind with me as to the value of Royal Sovereign. In my first note on this variety (p. 262) I mentioned that as a foreign Strawberry it had proved earlier and a

heavier bearer than Noble. I have been unable as yet to give it a fair trial out of doors under the same conditions as Noble, and I am therefore not in a position to state how it will compare, in this locality, with the latter variety as to earliness in the open. I note, however, that Mr. G. Wythes (p. 441) and "W." have both found it to be rather later than Noble. That Noble is a paying Strawberry there can be no two opinions, the fruits being full-sized, firm, and of splendid colour, while during this dry June they have certainly been far from flavourless, and as a good and early variety for the market this Strawberry is at present without a rival, but I shall not be surprised if, in the future, Royal Sovereign proves itself even more valuable, though I think that the Strawberry which ousts Noble will have to be possessed of many good qualities. The old Sir Joseph Paxton is still a favourite in this neighbourhood, and has, as usual, borne well, though perhaps not quite so heavily as Noble. John Ruskin has been poor both under glass and in the open, and will not be grown again. Competitor has produced marvellous fruits, there being no difficulty in finding eight berries to make up a 1 lb. punnet. There seems to be much diversity of opinion as to the flavour of this Strawberry, some, amongst whom I must include myself, finding it insipid, while others prefer it to varieties possessing a more decided taste. Waterloo, with its dark, almost black colour, has not an attractive appearance, but it has the merit of a particularly pleasing flavour and is a favourite with many for this reason. Latest of All has been more affected by the drought than any of the earlier varieties, as at the time the berries commenced swelling the ground was at its driest, and no just criterion can therefore be formed of its comparative value in an ordinarily moist season. —S. W. F., Torquay.

— This new variety secured the first prize in the single dish class at York show, and was a truly imposing dish, the fruit being large and brilliantly coloured. Although I much prefer the deep mahogany colour as found in the Gunten seedlings, I shall certainly grow Royal Sovereign, as many gardeners at York spoke very highly of it from every point of view. From its firm appearance I should say it is a capital traveller, which is a great point in favour of any Strawberry now-a-days when so much packing and consigning to a distance both by rail and parcel post have to be done. —N.

A NOVEL MODE OF PRUNING BLACK CURRANTS.

In judging cottage gardens in Essex the other day I came upon a lad sitting on the ground picking the Currants off a bough that had been broken off by accident. Remarking on this comfortable method of picking Black Currants on a hot day, my fellow-judge said that he had improved on that simple plan for years. He prunes his Black Currants so soon as the fruit is ripe, and carefully removes the fruiting branches to a clean packing shed or potting bench, where the fruit is picked under cover in cleanliness and comfort. The major portion or whole of the fruiting branches are then removed annually, the Black Currant bushes being pruned back to the young wood. The wood, being thus fully exposed in July, ripens thoroughly before the end of the season and produces full crops of the finest fruits. Of course, for this mode of culture the single-stem style of training is abolished in favour of the production of few or many suckers—from six to a dozen. The bearing wood and bushes to a great extent thus become annuals, and renew their youth as well as their vigour every year.

I have not hitherto adopted the early annual cutting back of my fellow juror. My experience, however, in regard to the wisdom of renewing Black Currants from suckers entirely agrees with his. His earlier and more severe pruning is also altogether in favour of the improved strength and fertility of the young wood

from base to summit, and his samples are mostly all alike good—a great point in dry seasons like the present. It is no exaggeration to affirm that nine-tenths of the Black Currants met with this year on bushes grown on the old crowded system are of no commercial value, the major bulk consisting of dry hard flesh, the skins being nearly as tough as an old shoe. But notwithstanding the persistent drought, the fruit on last year's shoots, where these have been fairly fed without overcrowding, is of average size and full of juice. And yet how many go on crowding Black Currants with old wood, cutting back the best of the young shoots into close spurs—a mere wanton waste of vital force and useful fruit. D. T. F.

#### NEW STRAWBERRY BEDS.

ALTHOUGH some time will elapse before actual planting of the freshly layered stock for next year's fruiting takes place, many will have already selected the plot, if not prepared it, for their reception. Early preparation of Strawberry ground is of much importance, as then a natural settlement of the same takes place before planting, and that a firm root-run is essential to their well-being has been proved over and over again. Put out two batches of plants, the one on fairly solid ground, the other on ground quite freshly trenched or even dug, and should the autumn prove dry it will soon be apparent which suits them best, and that, too, in spite of all the treading which may be given at planting time. True, ground cannot always be cleared of other crops soon enough to allow of this early preparation, but where practicable it should always be done, even if only a fortnight beforehand. When living under that veteran Strawberry grower, Mr. Allen, of Gunton, I became convinced of the necessity of giving a firm root-run to young Strawberry plants from the success he had from the practice. His plan was to select a plot of ground in spring. This was trenched one spit deep, a good quantity of rich manure being dug in at the same time. The garden roller was then put over it, and in due time the main crop of spring Onions sown in rows 2½ feet apart. The frequent trampling of the ground to attend to the crop during the summer rendered it very firm and solid, and in August the young Strawberries which had been layered from the previous year's planted bed were planted out 2½ feet apart between the rows of Onions, the soil being well rammed in round the balls. This he did every year, and finer fruit than was produced from these beds I never saw. So much then for a firm root-run. Now, in regard to trenching, I am opposed to the two-spit system as practised by many, especially if the plants are to be destroyed after the second year's fruiting. The Strawberry is to a great extent a surface-rooting subject, and in my opinion the roots do not during the first year, when we expect the largest and best fruit, reach the manure thus deeply buried. What I prefer is to take one spit and the crumbs and to tread the manure in the bottom. The young plants then get the benefit of it as soon as in active growth, fine fruit is produced the first season, and a heavy mulching of pig manure applied in November or December—the same being long, but thoroughly saturated with the urine, fortifies the plants against the strain of the second year's crop, after which they are destroyed. The reason why so many Strawberry beds on light warm soils collapse during hot dry seasons is that autumn mulching is neglected, a little littery material being put round the plants just as they are coming into bloom, by which time often three parts of the moisture has escaped from the soil. In such cases early

and good runners cannot be obtained, as the parent plants are invariably badly affected by spider. In planting young beds I always give a cube of good sound loam, ramming it well in round the balls and mulch with spent Mushroom manure or even leaf-mould to the distance of a foot round each plant, and if the autumn proves dry give a couple of waterings with farm-yard liquid at an interval of a fortnight after growth becomes vigorous. In many large places where the demand for pot and open-air bed plants is great, many runners are annually taken from two-year-old beds. This is a two-fold evil, the stock in the first place being weakly and smothered by the foliage of old plants, and trampling amongst the rows being a great nuisance. If those who have room would utilise the ground by the margins of walks and in front of espalier trees for growing runners for stock, keeping all the bloom pinched off, they would find it an advantage in every way. Some of the old Strawberry growers, Mr. Coleman, of Eastnor Castle, for instance, used to devote a separate open sunny quarter of good ground each year to young plants for producing runners, allowing them to stand one year only and keeping the bloom pinched off. This may by some be thought extravagant, but were I in a position to do so I would adopt the plan myself, as I am confident it would pay in the end. When stock plants are grown by the margins of walks I see no reason why the young plants should not be layered into the fruiting pots at once instead of into small ones; the too common evil of the plant becoming root-bound before potting is accomplished is thus avoided. Planting before this root-bound condition is reached is one of the main points in good open-air culture. If the young plants are at all infested with spider I lay them on their sides and well syringe with sulphur water. This will cleanse them and secure a healthy growth. J. CRAWFORD.

**Apple Earl Morrin.**—This capital cooking Apple was inadvertently called Earl in the note on it in THE GARDEN June 15. It is mentioned in various trade catalogues, but is not, I think, generally known, which it certainly ought to be.—J. C.

**Beetles eating Strawberries.**—Strawberry growers often have to complain of the great amount of damage and loss sustained by slugs. This year, owing to the dry weather, these pests have been less numerous than usual, but another enemy in the form of a small black beetle is doing much mischief in some districts, eating holes through many of the finest fruit and damaging others. One can guard against slugs to a certain extent by liming round the base of the plants before mulching, but the beetles travel from a distance, and are not, therefore, so easily kept at bay; indeed, I know of no effectual trap for these pests, and should be glad to learn if other gardeners have discovered one.—C. H. N.

**Grape Duke of Buccleuch.**—Last season I grafted Duke of Buccleuch on to Golden Queen stock, and have this season one bunch on the rod. I am in hopes that the union will prove a happy one, as although there are certainly one or two spotted berries in the bunch the majority of them are clear and of large size, also colouring early and well. I shall hope to report further on the Vine next year. The Duke is more often than not found in a ragged and unsatisfactory condition, owing to the well-known spot that affects the berries, but it is just possible that Golden Queen, which has been proved to be a good stock for many capricious varieties, may be suitable for the Duke; at any rate I have good reason to hope so from the appearance of the bunch in question.—N. N.

**Early Peaches.**—It is remarkable how soils alter the size of fruits, as at p. 461 Mr. Markham says Amsden June did not grow so large as

Waterloo or Alexander, and did not crop so well as the two named, but he thought the flesh was sweeter. Here Amsden June is quite the reverse; in fact, I have discarded Alexander on account of its being smaller and not so good as Amsden June. As most fruit growers know, soils have much to do with the size and quality of fruit. My soil is lighter, I fancy, than Mr. Markham's, but it is not considered nearly so good as the Kent land for fruit. I am almost inclined to think the Amsden June is not always true to name, as under glass with me it is a remarkable cropper, the fruits fine, and very early. Again, much depends upon the stock upon which the trees are worked and, of course, the culture given. I think it was "J. C." who advised me to plant Amsden June on the open walls, and certainly I have had no reason to regret doing so, as trees after having been planted nine months gave fine fruits and of good quality. Though last year was a poor Peach season in the open, this was the first Peach ripe. The trees promise well this year, being very healthy and making a lot of good wood. I can, like "J. C.," speak as to the good qualities of Early York for open walls. It has done well with me. It is useless to expect these American Peaches to grow alike in districts totally different as regards soil and situation. It cannot be denied that the early American kinds are a great gain, as they give us fruits in the open so much in advance of the older kinds, and though inferior in flavour, the first Peaches from the open are too useful to make us complain much.—G. WYTHES.

#### BLISTER ON VINE LEAVES.

ANY criticism by "D. T. F." is most acceptable, because always rendered in a kindly, courteous manner. No doubt deep root action does contribute towards blister, owing to the flimsiness of the foliage formed under such conditions, but I still think faulty ventilation principally to blame. What "D. T. F." says concerning the risks attending the practice of leaving or keeping up a little heat in the hot-water pipes is to the point, and worthy of close attention. I very well know there is a certain amount of risk attending the practice, as I have frequently been greatly vexed to find the pipes too hot when the sun-heat had also risen considerably. They would not cool, and red spider was perhaps the outcome of one or two such blunders. When, however, fire-heat is wholly dispensed with in warm, clear weather there is an even worse evil to be reckoned with; at any rate, in the more moist western counties, and probably to a certain extent in the drier eastern counties, where "D. T. F." has practised so long and so successfully. I refer to scorching of the leaves and scalding of the berries. Both occurrences are due to faulty ventilation and false economy as regards fire-heat. After a clear, hot day the maintenance of a comparatively low night temperature results in the condensation or deposition of moisture on the leaves, all the edges of these being prettily fringed with dewdrops. This may appear satisfactory enough, and to a certain extent it is so, but when this moisture is evaporated too quickly, scorching of very many of the leaves is almost inevitable. Gros Maroc is peculiarly liable to this form of scorching, and Black Alicante, Black Hamburg, and, in fact, all other varieties, are more or less liable to suffer from it. It is at the coldest ends and where also the sunshine first strikes that most leaves are scorched, and very early ventilation, without fire-heat, will not always meet the case. Disfigurement of leaves is annoying enough, but wholesale scalding of the berries is at times even more so. This latter is brought about in much the same way as scorching of the leaves. The berries, always cool, appear to become ice cold during the night in unheated houses, and a slight rise in the temperature, even if air is given quite early, ends in the deposition of moisture on the berries, rapid evaporation, brought about by sunshine, resulting in the scalding of a few or many berries. That, I believe, is the correct theory, and for which I am not responsible, but am a believer in. The

remedy in both cases, then, is the maintenance of gentle heat in the hot-water pipes. On dull mornings if there is no heat turned on, a burst of sunshine may raise the temperature in a house very rapidly and the berries be dewed over before it is possible to prevent it without the aid of fire-heat. In low positions there is particular need of great care and a freer use of fire-heat, or otherwise it will be impossible to keep up a circulation of dry air. Am I right or wrong, therefore, in advising the maintenance of a "little heat" in the hot-water pipes? There ought certainly to be no reckless stoking in connection with Grape growing, and no very great judgment is needed to keep the heat down to a reasonable extent.

W. I.

**Fig White Marseilles.**—Has any reader of THE GARDEN found this Fig to be subject to a spot in the leaf which when it once sets in increases rapidly? I have this Fig growing in tubs

advisable to use more nails than is necessary. Often small sticks and matting twisted or strong raffia will keep the intermediate shoots in position, thus saving nails and doing the work more quickly. Pyramid trees or bushes in the open should, if possible, be given a mulch and will well repay copious supplies of moisture or liquid manure. Large trees often drop their fruits when stoning if the roots are parched.—G. W.

## FLOWER GARDEN.

### A BASKET OF DORONICUMS.

A VERY simple, but effective arrangement of flowers is shown in the annexed illustration. It consists of a light basket loosely filled with Doronicums (Harpur-Crewe) and the old-fashioned Ribbon Grass, with the addition of a

the plants kept well watered, and have a top-dressing or two. Hepaticas, which are apt in dry weather to lose their foliage early, are also helped by surface dressings after a good watering in the case of plants exposed to the sun. Division of Hepaticas should be done during a moist time in September.—R. D.

### IRIS KÄMPFERI AT WISLEY.

SEVEN thousand plants of this noble Iris need nothing more than a change of weather to yield the full measure of their beauty. The large well-established clumps have, however, come through the long period of heat and drought very well, and have thrown up flowering stems crowned with blooms, which, as regards form, colour, size, and substance, leave little or nothing to be desired. Smaller plants that have not had time to get a full grasp of the soil naturally suffer, for there are few hardy flowers that demand so much moisture in the growing time as Kämpfer's Iris. A copious rainfall would, however, put everything right and would ensure a bounteous harvest of bloom. The greater portion of the plants at Wisley are seedlings raised on the place, and there are yet thousands of young ones in the seedling beds only requiring a season or two to bring them into a bloom-bearing condition. There is ample opportunity to realise the decorative value of this Iris at Wisley, and certainly where it grows freely for some years it is one of the most effective hardy flowers we have. I do not wonder that Mr. Wilson has taken up its culture on so large a scale, for in grace of growth, nobility of aspect, and capacity for creating effect no other member of this large family can equal it. Some of your readers may not have formed so high an estimate of this species, but it must be borne in mind that the true value of any garden flower can only be correctly estimated when it is seen in really good form. There is a vast difference between plants that merely live on from year to year and such as thrive sufficiently to show their native vigour.

There is one little garden picture at Oakwood which I should like to describe, as it owes so much of its charm to this fine Iris, and illustrates what is probably the best way of cultivating it. In the foreground is a sheet of water, bordered on one side by a dense growth of our native yellow *Lysimachia*, with here and there an Iris backed up by the dense, intensely green foliage of the Alder. In other directions the gently shelving banks are freely dotted with Iris clumps, behind which rise somewhat steep mounds tenanted by dwarf hardy things and topped with flowering shrubs. Looking over the water, one sees the white and richly tinted blooms rising boldly from the green leafage, and rendered more conspicuous by the background of rockwork and bright masses of the little Cheddar Pink, white Thyme and other similar things. Photography could not do justice to this; it requires the painter's brush.

The water margin is undoubtedly the right place for Iris Kämpferi, for even in a time of drought there will always be a certain amount of moisture working up to the roots. In another part of the garden strong specimens fringe the margin of the pond where aquatics find their home, and the effect is equally good. Such a quantity of plants naturally requires a considerable amount of space, so that it has been found necessary to give to the seedlings a part of a field outside the garden. These are coming into

A basket of Doronicums arranged by Miss Jane Hodges. From a photograph by Mr. Greenwood Pim, Dublin.

both in a warm and quite cool house, and this defect is seen annually. It does not appear until the leaves are well developed, after which they soon look as if they had been syringed with hot water. Had this defect shown itself only in one house and temperature, I could have believed it to have been due to some cultural error, but I am now inclined to the belief that it is constitutional. Perhaps some reader or Mr. Wythes will give their experience with this Fig. I like the flavour of White Marseilles, it being sweet and refreshing and of fair size.—J. CRAWFORD.

**Plums.**—These are fruiting freely and making a strong growth, but white fly is troublesome, and unless well syringed the growth will be checked. Such insecticides as often advised and repeated hosing will be beneficial, and on dry soils a good mulch will do much to promote a healthy growth and ward off the aphid. Much useless growth may now be removed and will to a certain extent rid the trees of the fly. In nailing these or any other wall trees at this season, it should be borne in mind the work is only temporary, and it is not

single leaf of the Montan Peony. Flowers thus arranged are not only much more beautiful than when many sorts are crowded together, but they last longer, and when they are much in demand the supply goes much farther, a point of some importance in many gardens.

G. PIM.

**Double Daisies and Hepaticas.**—In southern localities the heat and drought are telling sadly on these plants, and on the Daisies especially. The shoots of the Daisy elongate, and they become bare of leaves towards the heart of the plants, letting in the heat to the main roots and bringing them into a debilitated state. The best thing to be done is to give a good root watering and then top-dress with some good soil, which will cause the side shoots to put forth roots into it, and create a valuable young stock for autumn planting; or the plants may be taken up, pulled in pieces, and the young shoots planted out in a prepared bed in a moist and shaded spot,

bloom, but being smaller feel the drought more. With a fair season as regards moisture there would be thousands of flowers in varying shades of colour, for this Iris is very variable. Between ivory-white and rich plum-purple one finds innumerable tints, some of them very delicate. Only yellow flowers are wanting, but these may come, for in some of the richly-coloured flowers the golden stripe is very pronounced, and this may develop. Diversity of form constitutes one great charm of this flower. The typical form appears to have three petals, not very broad, and the larger portion of the plants bears flowers of this kind, the petals ranging considerably in width. These æsthetic forms would find favour with many, but the florist's ideal is best realised in the almost circular flower with six broad petals, which are, however, much rarer. In every form and colour Iris Kämpferi is very beautiful, and should find a place in all gardens where suitable conditions can be accorded it.

Byfleet.

J. C.

**Malva moschata alba.**—This well-known hardy perennial—the white variety of the Musk Mallow—is now in fine bloom despite the frost of the past winter and the drought of the present summer. It has put forth very strong growths, and a line of it I saw a few days ago is a mass of white. The white variety, like the type (which bears rose coloured flowers), produces its blossoms in clusters at the points of the slightly branched stems. It can be propagated by division of the roots or by seed, which can be sown as soon as ripe in August and September or in early spring. Seedlings make strong plants, and there is little or no variation perceptible among them.—R. D.

**Sweet-scented Pæonies.**—It would be useful if any readers could give the names of the best sweet-scented Pæonies. I have a number of varieties, but, unfortunately, the names are gone. Some varieties are certainly very sweetly scented, whilst others equally as handsome are just the reverse, being most unpleasant. For border work this is not so noticeable, neither for this special purpose does it matter, but for house decoration those with the sweet scent are much to be preferred—in fact, those varieties with the "old Pæony" scent are quite obnoxious in the house. Where a quantity is grown, of course those with the sweetest scent are quickly picked out during the cutting. To many readers I am sure the names of the most sweetly scented would be most acceptable. Large bowls of the Japanese pattern filled with these noble flowers are very beautiful.—A. YOUNG.

**Lilium Hansonii.**—We have of late years been accustomed to see some wonderfully good examples of the different Lilies at Kew, and at the present time there is a remarkably fine display of *L. Hansonii* just at its best. This very distinct Lily is a native of Japan, where it was discovered by Maximowicz in 1860, but some years elapsed before it was introduced. Now, however, it crops up occasionally at the sales of imported bulbs during the winter months, and may be obtained when dormant from the numerous dealers in this class of plants. This Lily belongs to the Martagon group, its nearest ally being the typical *Lilium Martagon*. The bulbs are light in colour, firm and solid, and generally travel well. This species is one of the least affected by removal of the whole of the Martagon section, and it is also the first to make its appearance above ground in the spring. The leaves are produced in whorls, though occasionally broken up in an irregular manner; they are of a bright green tint. In size and general appearance the flowers are much like those of the common Martagon Lily, but the petals are unusually thick and wax-like, their colour being yellow, dotted more or less profusely with purplish brown. At Kew there are two beds of this Lily interspersed with evergreens, each mass having about 100 spikes, ranging in height from 1 yard to 5 feet, and altogether they form a very striking feature.

It is most essential to plant this Lily where it receives a certain amount of protection from neighbouring shrubs, as, owing to starting into growth so early, the young leaves are very liable to be injured by late frosts and cutting winds. Apart from this, it is perfectly hardy and is a good garden Lily, as it does not die off in the manner common to *L. auratum* and some other Japanese Lilies. With the plants of *L. Hansonii* at Kew is associated a specimen of that most interesting hybrid, *L. Dalhansonii*, raised by Mr. Powell, of Tunbridge Wells, between (as is indicated by its name) *L. Hansonii* and that dark variety of *L. Martagon* known as *dalmaticum*. *L. Dalhansonii* was illustrated in THE GARDEN, September 16, 1893, and reference to the plate in question will show the general aspect of the flower, though the Kew specimen is somewhat lighter in tint than that depicted. This hybrid is of good constitution and a valuable addition to our hardy Lilies.—H. P.

**Hose-in-hose Mimulus.**—I have a very fine deep yellow *Mimulus* spotted with dark that has developed the Hose-in-hose form, the calyx having become enlarged and coloured, and so forming a second corolla. It is not new, but it is interesting, because for years past I have raised many hundreds of seedling *Mimuluses*, but it is very unusual to find a Hose-and-hose form among them. A few years ago Mr. William Bull offered seed of Hose-in-hose varieties, but very few came true to character. Anyone having plants showing the Hose-in-hose form would do well to propagate it by means of cuttings. I have isolated my plant and will again test its capacity to reproduce itself from seed.—R. D.

**Nature v. Art.**—Nature often steps in and tells us what to do in the matter of plant grouping. This occurred forcibly to me lately, when noticing a spreading mass of *Rosa polyantha*, 30 feet or so across, not a close, dense mass, but thin in places, in which *Mulgedium Plumieri* has sown itself. The effect of the pale blue of the latter standing amongst and over the Roses, was very soft and charming. In another and damper spot *Sidalcea candida* has become a regular mass, amongst which the *Mulgedium* has introduced itself again, with the best effect. These are plants which can fight the natural herbage and take care of themselves. Again, a mass of *Spiræa filipendula* pl., with a backing of *Campanula grandis alba* with *Lilium Martagon album* interspersed, is good; a rather wild-spreading mass of *Campanula venusta* (the earliest of the *rotundifolia* group), in which some plants of *Papaver pilsomii* have introduced themselves, is very good also. A big mass of *Euphorbia lucida*, which has got into *Alstromeria aurantiaca*, is showy and very lasting. Again, in a smaller way, where a large stone is covered with *Thymus lanuginosus*, *Ajuga genevensis* has crept in and sown itself here and there amongst it; the effect of the deep blue on the grey carpet is excellent.—T. SMITH, Newry.

**Notes from Newry.**—Three interesting allied plants are in flower here together—*Ancimopsis californica*, *Houttynia cordata*, and *Gymnotheca chinensis*, the last a particularly graceful thing, with pendent tassels of white filamentose flowers. Amongst other more or less uncommon things are *Amanthium muscatolicum*, with dense, thyrse-like heads of creamy white; *Boykinia aconitifolia*, with flat heads of milk-white flowers; *Clintonia umbellata*, a beautiful plant, with umbels of pure white, a clump growing underneath a dense mass of *Diphylleia cymosa* remaining fresh for several weeks. I have one charming selection in which the flowers are quite covered with tiny pink dots. *Haplopappus pulchellus* has been, and is, beautiful, the dry, warm weather having just suited it. It is a yellow composite, of uncommon appearance. *Nerophyllum asphodeloides* has been very beautiful, large numbers having flowered this season. I find this does best in a little shade. As a sweetly pretty flower for a damp and shady spot, the double white Ragged Robin is desirable. Spreading masses of *Penstemon glaber*, *P. g. roseus*, *P. secundiflorus*, and *P. speciosus*, are beautiful. *Dianthus frigidus*, a pure white-flowered kind,

is excellent; *D. Duchess of Fife* is much like *D. Michael Foster*, but infinitely freer, while *D. Reuterianus* is a dense-growing kind, with flowers much like those of *D. alpinus*. *Thymus nummularius* has been added to the collection this season and is very good; the spikes of rosy flowers are from 4 inches to 6 inches long, something like *T. comosus*, but finer. *Hydrangea vestita* promises to become a tree; it has for several weeks borne flat clusters of white, mostly sterile flowers. My tallest specimen is about 7 feet, and the destructive frosts of winter, or those more recently in June, had no effect upon it.—T. SMITH, Newry.

**Anthericum liliastrum msjus.**—This beautiful plant, which was alluded to on p. 447, well deserves all that is there said in its favour, and it is not half enough grown, though it has been known now for many years. I first knew it in the once famous nursery of Messrs. Henderson, in the Wellington Road, St. John's Wood. The rather stiff soil of this nursery suited this *Anthericum* well, and it used to form a very attractive feature.—H. P.

#### CALOCHORTI AND LILIES AT COLCHESTER.

A VISIT to Messrs. R. Wallace and Co.'s nursery at Colchester is quite sufficient to dispel the erroneous notion which prevails and prevents many from even attempting to grow *Calochorti*, because they are believed to be difficult plants to deal with, giving very uncertain results. Almost everyone who sees them is fascinated by their grace, quaint beauty, and lovely colours. The groups of cut specimens that Messrs. Wallace have shown from time to time at the Drill Hall and elsewhere have attracted much notice, and without a doubt will materially serve to draw more attention to these flowers. But as it might be urged that the showing of cut flowers alone affords no indication of the growth or character of the plants, or in any way proves that their appearance growing in the garden is an ornamental or desirable feature, we went to see these *Calochorti* as they grow at Colchester, and were charmed with the picture they made. A large square-raised bed devoted to them alone was gay with myriads of blossoms open wide in the sun, the flowers looking like butterflies, alike in their quaint colouring, with eye-like blotches on the petals, and in their graceful poise upon the plants. Given the essential conditions of culture as here, indeed, it was evident that the reputed tenderness and delicacy were non-existent, and instead we saw plants of all sizes according to species, ranging in height from 1 foot up to 3 feet, and massed in the bed they were literally sheaves of bloom.

The tallest grower was *C. splendens*, which, in common with other species, shows marked variation. What is grown here as the type is a charming flower of a light lilac colour, its inner base clothed with a thick mantle of long silky white hairs and without any spot or stain of other colour. *C. splendens atro-violaceus* is taller and was quite a yard in height, the plants covered with flowers, which are of a deeper lilac-rose colour and have broader petals stained with dark red at their base. *C. venustus*, in great variety, is a host in itself, and the family would command our admiration if it consisted of this species and its varieties alone. Here again is abundant evidence of natural vigour brought out by adapting the cultivation to the needs of the plants. Who would say that *Calochorti* are delicate when one bulb of two years' growth, about the size of that of a good *Crocus*, sends up six flower-spikes, each nearly 2 feet in height and bearing thirty flowers? This was

done by a bulb of *C. venustus oculatus*, a truly lovely form with a long purplish bud expanding into a large flower, each petal having a black eye with a clearly defined margin of rich yellow, which shades to a lighter tint in the rest of the flower that is spotted at the base in an indescribable way. *C. venustus citrinus* is a richly coloured variety of the preceding, the ground colour lemon-yellow with a dark brownish blotch and chequered with reddish brown at the base. *C. venustus purpurascens* is distinguished by its deep purple exterior, but when fully open it resembles *C. v. oculatus* in its colour and markings. *C. v. Vesta*, a recent introduction, is a fine variety, robust in growth and free flowering. The flowers are large and handsome, a perfect harmony of quaint colour in yellow and brown, the latter shade forming an almost regular zone in place of the usual blotch. *C. v. roseus* is a well-marked variety in which the blotch is of a decided rosy tinge. These three last-named forms were all figured in a coloured plate in THE GARDEN of Nov. 3, 1894. *C. v. Vesta* is a gem, having a pale sulphur base, free from spots or markings of any kind. *C. v. pictus* is another neat and pretty form, whiter than any other variety in this group, with a small brown blotch and rosy spots at the base. *C. luteus*, with clear lemon-yellow flowers, which are spotted with red, is a bright and showy kind, but brighter still, and a sturdy, robust-looking variety is a new form of *C. luteus* named *concolor*. At present it is very scarce, but the plants we saw were vigorous-looking, the flower-stems stout and erect, bearing large open flowers of the richest buttercup-yellow, slightly veined and spotted with brown at the base. *C. macrocarpus* was just bursting its great buds, which expand into enormous flowers of a deep lilac tint, whilst the new and delicately-coloured *C. Lyoni* was fading. *C. Kennedyi*, too, was just out of flower. It is a brilliant species, with flowers of an orange-scarlet colour. A coloured plate of it may be found in THE GARDEN of February 11, 1893. All these Mariposa Lilies were growing and flowering in one bed—a rare assemblage of lovely flowers. In an adjoining bed an earlier section of this family was passing to rest. This embraces the *Cyclobotira* group and the Star Tulips. The former have globular, drooping flowers, and one variety—*C. puchellus*—was still flowering. It is a long and persistent bloomer and has rich yellow flowers. The Star Tulips have erect stems about 6 inches high, bearing open flowers, which appear at the same time as those of the varieties in the *Cyclobotira* section, so that the family can conveniently be divided into two groups for garden culture. The details of

#### CULTURE

as pursued with so much success here are of the simplest description, and those who like to imitate them may reasonably expect to be likewise successful. The *Calochorti* are grown in beds in the open ground, this having been found preferable to any coddling in pots or frames. They are much hardier than is generally supposed and really are more liable to injury from heavy winter rains than from frost. It follows, therefore, that a well-drained soil is one of the first essentials, and to facilitate this the beds at Colchester are raised above the surrounding level of the ground and have a slight slope to the north. The soil is made very porous by an abundant use of grit, the bulbs are planted in November and a covering of reeds given, which answers admirably in throwing off an excess of moisture. This is removed as growth advances early in spring. When in full growth they want abundant moisture, as the

porous soil soon dries up, and after flowering thorough ripening should follow. This can be facilitated by placing lights over the bed, or the bulbs may be lifted, replanting them again the following November. *Calochorti* being lovers of the sun, the present season has been a favourable one for them, but in the hands of Messrs. Wallace they are no longer in the experimental stage, and in years of less sunshine they flower them well under the conditions of treatment indicated above. There are many gardens in warm districts and on dry soils where these flowers may be grown, and, failing natural aids or climatic advantages, *Calochorti* are even then worthy of the trouble involved in any special preparation of a site for them.

#### LILIES.

These, in infinite variety, are a special feature, and Messrs. Wallace deserve credit for their endeavours to popularise them. *Lilium Thunbergianum*, or *L. elegans*, as now generally called, was flowering in many fine distinct forms of varying heights, especially noticeable being *atro-sanguineum*, with its deep red flowers, *Van Houttei*, of a deep, dark crimson-scarlet, and *Alice Wilson*, most distinct, with lemon-yellow flowers, having a band of a deeper yellow hue down the centre of each petal. *L. elegans Wilsoni* is a good form, tall, robust, and one of the last of these varieties to flower. *L. canadense* was abundant in several distinct varieties, yellow and deep orange, the flowers much spotted and gracefully poised in a pyramidal head at the top of a stout stem. *L. Grayi*, of similar habit to the preceding, was flowering well. It is a comparatively new kind and an acquisition, the flowers drooping, bell-shaped, of a rich red colour, with dark spots. *L. Parryi*, another uncommon, though by no means new species, was also in bloom. Its flowers are yellow, freely spotted with dark brown. *L. Krameri* was prominent in bud, and *L. Leichtlini* was represented by a strong batch. *L. Coridion*, a dwarf and graceful Lily rarely seen, was flowering also, the blooms of a rich citron-yellow colour. *L. Humboldti* was conspicuous, its tall stems terminated by fine heads of purple spotted yellow flowers. A batch of *Burmese Lilies*, supposed to be *L. Lowi*, gave promise of something new, as in addition to the true *L. Lowi* were one or two more, differing from it and from every other Lily in this large collection in growth, one noticeable form having distinct downy purple-tipped leaves. *L. Henryi*, although wanting some weeks yet before expanding its rich flowers, must be mentioned for its robust growth. Happily, it comes into that class that wants no special preparation, but succeeds in ordinary garden soil, and without a doubt it is one of the garden Lilies of the future. We saw large beds of it, and they were perfect thickets of luxuriant growth, even small imported bulbs of last year having shoots already 4 feet in height. It has been well described as an orange-yellow *L. speciosum*, and although we might say it is hardly acclimatised as yet, there was no other Lily in this large collection more luxuriant.

Those here enumerated by no means represent all that were in flower, as we have purposely mentioned the rarer species that are not as yet much seen in gardens. It will suffice for the rest to say that all the older and better-known garden Lilies are equally as well grown.

***Inula Hookeri*.**—Is there not some mistake about this? The true *Hookeri*—at least, as I know it—does not flower before August, and its flower-heads, instead of being 2 inches to 3 inches across, are at least 4 inches over. Is not the plant to

which the certificate was given, *I. hirta*?—T. SMITH.

***Mertensia virginica*.**—With respect to the American Cowslip blooming in May, queries anent which appear on pp. 447 and 467, I may mention that the plants alluded to by me in my notes on "May in South Devon" were flowering during the first week of the month in a shady spot, but, as "W. H." (p. 467) remarks, are at the present quite dormant.—S. W. F., *Torquay*.

***Campanula grandis*.**—This Bellflower is at present an object of great beauty in the flower garden. Both the coloured and the white varieties are charming, but the latter is certainly the more effective both in the herbaceous border and when used for indoor decoration. Growing in good soil, the flower-spikes reach a height of over 2 feet, the individual blooms, that are of a shining satiny white, often exceeding 2 inches in diameter, and being of more lasting character than those of most of the *Campanulas*, comparing favourably in this respect with the well-known and widely grown biennial, the Canterbury Bell (*C. Medium*). The plant is easily increased by division, and a small one will in a couple of years form 50 or 100, as the clumps spread so rapidly, that if left alone they soon form dense masses a yard or more in diameter. This *Campanula* is now rarely to be met with in this district except in cottage gardens, but it is well worthy of a place in the collection of the lover of beautiful flowers—far more worthy indeed than the tender bedding plants, such as *Geraniums*, *Calceolarias*, and *Lobelias*, for whose sake it has been in many cases ousted.—S. W. F., *Torquay*.

#### NOTES ON HARDY PLANTS.

***Veronica cupressoides*.**—All the conifer-like *Veronicas*, or, as they are sometimes aptly called, the Whip-cord section, are known to have been extremely shy bloomers so far, and we have had since their introduction a fairly wide range of seasons, as very hot and very wet summers, and mild as well as very severe winters. It does seem strange that these plants are flowering better after the severest of our winters than have been their wont, and especially when we recall that their native climate never has such low temperatures. Another peculiarity is that the inclement winter of 1894-5, following on which some are flowering as they have never done before, has killed more of the species of this section than ever I experienced before. Let us hope that the flowering of some is not caused by a reduced state of the plants constitutionally, as we have often seen to be the case. This certainly would appear to explain the flowering of some and the death of many after the hard winter, and I must confess that the general appearance of my plants favours this view.

***Scabiosa succisa glauca*.**—This is a pleasing variety of the common Devil's-bit. The flowers are rather larger and somewhat brighter than in the wilding, but, I am sure, many would like it for its pleasant perfume, which almost exactly resembles that of the Elderflowers. A good piece of it stands by the walk side, and many stop and ask what the sweet scent comes from. The plant is a rather strong grower and not quite suited for the choicest borders, but wherever sweet smelling plants are desired this is worthy of note.

***Gaultheria tricophylla*.**—I enclose one or two of the big berries of this little creeper. I have several times before in these notes mentioned this Indian species. It gets into fruit early and the berries last for many weeks in the pleasing pale blue colour now to be seen. A friend aptly described the effect of a fruiting plant the other day. He said, "It could easily be taken for a creeper among which some bird had laid its eggs." The plant never grows higher with me than 1½ inches, and in moist peaty soil and sand runs freely. The flowers are large, but owing to their lurid brown colour are inconspicuous. Soon, how-

ever, the berries swell and colour, and then the deep evergreen foliage is enlivened in the most charming manner.

**Dianthus Sternbergi.**—This is a neat and distinct variety or species—I cannot say which. There are several nearly like it in many points, as *gelidus* and *frigidus*, but in one respect at least it is well marked as differing—its foliage is very short, rigid, squarely set on the stems, and so thick as almost to resemble some of the *Mesembryanthemums*. The flowers are each 3 inches high, white, with deeply-fringed petals and a sepia-coloured eye. It grows here close to a tuft of the very spiny *Acantholimon androsaceum*, which it well matches for the glaucous hue and stiff and pointed leaves. It has none of the miffiness of the softer-leaved *Dianthi* such as *glacialis* and *alpinus*, and I have never seen its leaves bored by grubs, which trouble me more than anything else as regards alpine Pinks. J. Wood.

Woodville, Kirkstall.

### FLOWER GARDEN NOTES.

**SUMMER BEDDING PLANTS.**—A season like the present brings out very clearly the advantage of putting out well-prepared plants of good size rather than weakly stuff, that being crowded together in boxes has very often the greater portion of its roots torn away in the removal and is a long time making any show, especially if the weather keep dry for several weeks following planting time. Plants, on the other hand, turned out singly from pots if thoroughly well soaked receive no check, but start into growth at once, and where this is the case flower gardens are looking very gay, especially when the fact is taken into consideration that for the last two months we have hardly had enough rain to damp the surface of the ground except a very slight shower about the middle of June. I said above, plants turned out singly from pots were producing the best effect, but to these must be added batches of sturdy hardy plants, cuttings of which were inserted in autumn, transferred thinly for a time to a well-prepared bed, and when required thoroughly soaked with water and carefully lifted to avoid any mutilation of the root. Antirrhinums are among the best of our hardy plants in a dry season alike in the formal garden and herbaceous borders, and I am very pleased with the habit and flowering properties of three distinct shades in white, crimson and yellow that were selected last year from a batch of seedlings and propagated in the autumn of 1894. Beds of considerable size can be made very beautiful by planting the Antirrhinums in bold clumps and filling in with dwarf *Ageratum*, *Mesembryanthemum*, *Manglesi Pelargonium* and *Vesuvius* or *Ball of Fire Tropaeolum* as the colours may be required. Possibly *Vesuvius Tropaeolum* is the very best plant that can be found to associate with a vigorous strain of white Antirrhinum. Other hardy plants that show to advantage on a dwarf white carpet (planted together in sufficient quantity so that one gets a good idea of the beauty alike of flower and foliage) are the varieties of herbaceous *Lobelia*s. The remarks above as to the advantage of turning out well-established plants from single pots or to so manage as to avoid root-mutilation are peculiarly applicable to bedding *Tropaeolum*s; they are so tender and brittle in root and foliage, that when once they are allowed to get crowded separation is not an easy matter. Those who want a first-rate dry-weather plant as a dwarf yellow cannot do better than trust to Mrs. Clibran *Tropaeolum*. It is far more enduring in a season like the present than *Calceolaria*s or yellow *Viola*s. *Pelargonium*s, whether zonal, variegated, Ivy leaved or scented, are all looking much better than at the corresponding time in 1893, a season we have matched in the matter of prolonged drought, although possibly not in the amount of actual sunshine or intense heat. Growth made is sturdy rather than vigorous, and those varieties grown for their flowering properties are a mass of bloom. I do not care much about the variegated or tricolor forms, but

make an exception in favour of *Manglesi*, *Lady Plymouth* and *Chelsea Gem*; the double pink flowers of the last contrast beautifully with the bright variegation.

**HERBACEOUS BORDERS.**—Many inmates of these borders show unmistakable signs of the effect of the continued drought, and in all cases where watering is practicable a thorough soaking should be given. Tufted Pansies, for instance, are hardly likely to throw cuttings in quantity unless they get more moisture than is this year naturally provided; indeed, unless abundance of rain comes, and that speedily, we shall in the case of this flower have to rely on later propagation by division instead of July cuttings. There are few places that have been less visited by the heavy showers than this particular part of North-west Surrey. Storms have worked up, but have split at a comparatively low point in the heavens, and passed with aggravating persistency to the right and left. A good soaking will be necessary to secure a second growth and display of flower on the *Pyrethrums*: at present they are not moving an inch. Most of the *Spiræas*, where fully exposed to the sun, are losing their bottom foliage, and the display of flower will be short-lived. As in the case of fruit trees and vegetables, a mulching should always accompany the watering of herbaceous plants, and it is advisable to see to it if possible before the plants begin to suffer. Of course in the majority of cases watering long stretches of herbaceous borders is quite an impossible matter; things have to take their chance, and the only relief one can afford is to put on a mulching of some kind to keep the soil from drying out so quickly. Following up in connection with such borders the few selections made above as to good dry-weather plants, it may be noted that there are some that look remarkably well and appear in no way affected by the lack of moisture. The varieties of *Thymus*, *Sisyrinchium*s, *Linaria*s, *Centaurea*s, *Veronica*s, *Gaillardia*s, *Anchusa italica* among tall and the old double *Chamomile* among dwarf plants are all cases in point. Pinks and Carnations in variety also come very well through a dry summer, but to secure this two cultural points are essential. The first is well-prepared deeply-dug borders in which a liberal dose of mushroom or peat moss manure has been incorporated, and the second is a good surface mulching preferably as soon as the beds are planted in autumn, as the moisture is thereby well retained. I have been waiting for rain in order to take up and divide the best of the *Polyanthuses* selected from this year's display. If it is absolutely necessary to transfer them before the long-desired rain comes, I shall have a tub handy and give them a good soaking before replanting. Big plants of *Polyanthus* naturally draw and impoverish the soil in any season, and just at present the border in which they are growing is as hard as a road and as dry as powder. If a batch of seedlings is ready for transplanting from the spring sowing, it will be found advisable to soak them thoroughly a few hours before lifting. Where old plants were left for seed they will require looking through daily. As the seed is now ripening up, it is a favourable time for harvesting the same, very different from that of last year, when the rain spoiled a rather large percentage of the pods. Seed boxes of herbaceous plants sown during May or June will want attention in the way of a light watering if the seedlings are showing, and continued shade during the hottest part of the day if they are not yet peeping through, also a night inspection for slugs if these are likely to be troublesome, or they will be the first to find the tiny seedlings and do a lot of mischief in a single night. E. BURKELL.

Claremont.

**Anomatheca cruenta.**—This is a remarkably pretty little bulbous plant, a native of the Cape of Good Hope, and nearly hardy in this country. It produces a bulb a good deal like that of a *Freesia*, but smaller, while the sword-shaped leaves are disposed in two rows as in the *Montbretia*, to which this little *Anomatheca* (before the flowers make their appearance) bears a certain

amount of resemblance. The flowers, which are produced on scapes from 6 inches to a foot high, are nearly an inch across, in colour bright carmine-red, and composed of six segments, the three lower ones being blotched towards the base of the petals with rich velvety crimson. It seeds very freely, so that if a few pots of it are employed for the embellishment of the greenhouse and the seeds are allowed to ripen, the probability is that during the following season young plants of it will crop up in many directions. Unlike most bulbous plants, the seedlings soon attain flowering size; hence if the seed is sown when ripe the young plants so obtained will bloom the following season. As the flower-spikes are pushed up freely and there are several blossoms on a scape, it is an object of beauty for a considerable time. This *Anomatheca* is a plant of very easy culture, and may be treated in various ways. A very good plan is, when dormant, to shake the bulbs out of the soil in which they have been growing, and winter them covered up with sand and placed where just free from frost. Early in the new year they may be potted, using an open loamy soil. From eight to ten bulbs in a pot 5 inches in diameter will form effective little clumps.—H. P.

**Gypsophila elegans.**—The *Gypsophila* seems to have become an indispensable flower, and even the flower-sellers in the streets use much of it in the place of Fern for giving lightness and grace to button-holes and sprays. The variety at present in use is *G. elegans*, a hardy annual, having the same elegant habit as the later and perennial species (*G. paniculata*), whilst its flowers are larger. Between the two a very long succession of this flower can be maintained, and those who have to supply cut flowers in quantity will find them both worthy of their attention. At Syon House several sowings of *G. elegans* are made to keep up a supply of its flowers till those of *G. paniculata* in the borders appear, whilst a late sowing of the annual kind again comes in after the perennial sort is over.

### PINKS.

For years Mr. Ladhams, Shirley, Southampton, has paid much attention to the growth and improvement of the Pink. A really good form of border Pink having distinct markings and freedom of flowering and perpetual is a gain. The one he prizes above all, and which he raised and named after his son (Ernest Ladhams), is now well known as being the best perpetual flowering Pink in commerce. The soft pink colouring is at all times so pleasing; its fragrance, too, none object to. I lately saw one huge bed of this variety containing 1000 plants, and as they were literally smothered in bloom it was a grand sight. For flowering in pots, too, during April this Pink is valuable. Hundreds of seedlings Mr. Ladhams has at the present time on trial. Many of them appear to be a distinct advance upon older kinds. Helen Holmwood is a sport from the well-known Charles and in every way an improvement, being more robust. The white ground is heavily marked with bright pink. Jane Duval is quite perpetual in its flowering, purple markings on a white ground; the flowers are freely borne on stout, erect stalks. Southampton has large flowers, soft pink, with deeper blotch. The above varieties were raised during the present year by Mr. Ladhams. The best of his 1894 varieties are Charles and Morning Star. The former is especially robust, much like Anne Boleyn, but deeper in colour, bright pink, with deeper markings. The following are also of Mr. Ladhams's raising, he having free-flowering border varieties more in mind than exhibition blooms pleasing to the florist only: Caroline, white, with a faint blotch of pink in the centre of each petal; Fashion, of quite a novel shade in Pinks, almost single, but very showy; and The Lady, semi-double, bright pink, each petal marked with a deeper blotch at its base. Queen of the South is quite a fortnight earlier in opening its flowers than Her Majesty. The flowers are freely borne on stout

F. SMITH

stalks and have less tendency to splitting than many others. Many more might be named, but the above will give some idea what is being done to increase and improve the race of border Pinks. At a recent meeting of the Shirley Gardeners' Association Mr. Ladhams exhibited forty varieties. The seed is sown in January in a cool greenhouse, thus enabling the plants to have a long season of growth. Many of the plants flower the same year. E. M.

**Lathyrus magellanicus.**—Will any reader tell me where I can get *L. magellanicus* (Lord Anson's Pea, introduced by his cook, 1744), a maritime plant? (See Loudon's "Ladies' Flower Garden," p. 150, plate 36.)—D.

\* \* \* The answer to this query (a very common one, by the way) is that the true *L. magellanicus* (Lamarek) is probably not now in cultivation. I know of no one possessing it. By an unpardonable blunder the name Lord Anson's Pea has been given to the blue var. of the common annual *L. sativus*, which has nothing in common with it, though not without merits of its own. It is greatly to be desired that seedsmen and seed growers would mutually agree to relinquish this name. For ignorance there might be some excuse, but there is none for a wilful persistence in the employment of a name which excites a fallacious hope in the mind of the purchaser. This Pea is, in short, the horticultural "Mrs. Harris," having practically no real existence but in the pages of botanical works. I will venture to add, that could it be re-introduced, it would probably be found to possess less real value than its seekers imagine.—W. THOMPSON, Ipswich.

GARDEN FLORA.

PLATE 1022.

TECOMA SMITHI.

(WITH A COLOURED PLATE.\*)

As a greenhouse plant for this country, *Tecoma Smithi* is by far the best of the genus yet introduced. All the species in cultivation have beautiful flowers, but they are, with scarcely an exception, shy-flowering, and for this reason are but little grown. *T. Smithi*, however, does not possess this character. Plants were raised from seed at Kew in 1889. These flowered in the autumn of the following year, and these plants, or others raised from them by cuttings, have flowered every year since. This may, indeed, be described as one of the best greenhouse plants introduced in recent years, and a first-class certificate was granted it by the Royal Horticultural Society in October, 1893. It is of sturdy, erect habit and has pinnate leaves, the leaflets being 1 inch to 2 inches in length, oblong and serrated. The flowers are produced at the ends of the shoots between the months of September and January. They occur in large, erect, compound racemes, which are sometimes as much as 7 inches or 8 inches in diameter and the same in length. The flowers, which on the larger racemes number several scores, are tubular, more or less drooping, and 1½ inches to 2 inches long, with five reflexed lobes to the corolla. Their colour is a bright yellow, tinged with orange. This *Tecoma* was raised by Mr. Edwin Smith in Australia, and its parents are said to have been *T. capensis* and *T. velutina*. If it be really a hybrid, the fact of its coming true from seed makes it an

\* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon, January 11, 1895. Lithographed and printed by Guillaume Severeys.

especially interesting one, for it is well known that most hybrids when propagated by seed show much variation, and revert back at each successive generation more and more to one or other of the parents. Mr. Guilfoyle, the director of the Botanic Gardens at Melbourne, who first sent seeds to this country, says that in Australia *T. Smithi* flowers for at least nine months of the year; it is therefore an exceptionally valuable plant for sub-tropical climates.

**T. CAPENSIS.**—This species is worthy of mention as being the one most frequently grown in gardens. It is of semi-scandent habit and may occasionally be seen treated as a climber on the roof of a greenhouse. Its thick, strong growth renders it better adapted for clothing pillars, &c., than for a place on the roof where it obstructs the light. It is as shy-flowering as most of its fellow-species, and when kept indoors all the year it is only after exceptionally long, hot summers that it blooms. When treated as a pot plant, however, and exposed out-of-doors to full sun and air during the summer months it blooms freely enough. Its racemes are terminal and the flowers are of a brilliant orange-scarlet. It was introduced from the Cape of Good Hope in 1823. This species might be made one of the winter glories of the Riviera. I remember seeing a group of it in the Acclimatisation Garden at Hyères one October day some years ago which was simply a blaze of fiery scarlet.

Like most of the Bignoniaceous family, the *Tecomas* are vigorous growers, and it is a very easy matter to obtain strong, healthy plants. They like a rich loamy soil, lightened by the addition of coarse silver sand and leaf-soil. When grown in pots they may be freely supplied with manure water, more especially after the young racemes have formed. As already stated, it is in the production of flowers that the gardener's skill is most needed, more especially with such sorts as *T. capensis*, *T. McKeni*, &c., *T. Smithi* not being difficult to flower. Abundance of sunshine and fresh air are the two chief factors; plants grown indoors all the year round only flower after exceptionally long, hot summers, and not then, even, if they are in shady positions or far from the glass. It is, consequently, the best plan to grow them in pots, so that during the summer they can be taken out of doors and exposed to full sunshine. Small plants consisting of a single stem may be had in flower within nine months of their being struck, and both *T. Smithi* and *T. capensis* make very useful plants when grown in this way for autumn flowering. The cuttings should be taken as early as possible in the year, making them of half-ripened wood and about 3 inches long. These should be struck singly in 2½-inch pots in a brisk bottom-heat. The plants should be grown on quickly in a moist greenhouse until about the middle of June, when, according to their strength, they will be in pots 5 inches to 7 inches in diameter. They should then be hardened off a little in a cool frame and afterwards stood outside in a sunny position. Towards the end of August racemes will be pushing from the tops of the shoots (which ought never to be stopped), and they may then be placed in a frame again, keeping them moist and fed with manure till the racemes are well advanced. Axillary shoots almost invariably begin to push at the same time as the raceme, but should always be removed, so that the entire strength of the plant may be concentrated in the inflorescence. These one-year-old plants vary from 1 foot to 2 feet in height. After flowering they may be wintered in a cool frame, cut back in spring and grown on as before. In the case of *T. capensis*, however, the plants appear to flower with greater certainty when grown on from cuttings each year. W. J. B.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

**FRENCH BEANS.**—These, where growing in rough home-made frames, will now have borne most of their crop, and in order to make the most of the young pods just set and setting, it should be seen that no old pods are hanging on the haulm, these having a most impoverishing effect. A thorough soaking also of farmyard liquid should now be given to aid in swelling off the remainder of the crop. Successional batches coming on in the open garden must likewise now receive attention. Mulch with short manure, old Mushroom manure, or even lawn mowings, soaking the same thoroughly with liquid manure. Younger batches must now have a little soil drawn to them to steady them, but as the soil in most gardens is still in a very dry state, the ground between the rows should receive a good moistening the previous evening. Another sowing may now be made, adopting the previously advised plan of using three sorts in equal proportions, Canadian Wonder still being one of them. For a July sowing, Canadian Wonder will be best omitted, earlier sorts, such as Sion House and Webb's Victoria, being substituted. To all future sowings allow plenty of space both between the rows and plants, and also a good rich root-run. Sow the seeds in shallow drills, finally leaving the soil in these somewhat below the ordinary ground level. It is also advisable to soak the ground after being dug before sowing the seed. Canadian Wonder will sometimes on good soil grow to a great height, and be, in consequence, rather tardy in coming into bearing; to mitigate this latter evil, pinching may be resorted to when the growth has reached 18 inches. French Beans are much benefited by an overhead watering several times weekly in the evening. By this the foliage is kept free from spider.

**SCARLET RUNNERS.**—The present season is not the most favourable for the well-being of this popular vegetable, there being a too arid atmosphere to favour the free setting of the bloom and the rapid swelling off of the young pods. To meet this deficiency extra labour is needed in the shape of heavy root mulchings and copious drenchings. This can more easily be done both in the case of Beans and other growing crops this summer, as, owing to the protracted drought, hoeing has been reduced to a minimum. By all means keep the pods of the first yield of Scarlet Runners closely picked in, this allowing the uppermost portion of growth to become vigorous and to form stout bloom-trusses. If a hose or garden engine can be turned on to the rows towards evening now and again it will be of great benefit, assisting to set the blossom and aiding in keeping the foliage clean and healthy. Another sowing may yet be made of Painted Lady, a quick-growing early yielding variety, the growth being pinched and no stakes used, as in field culture. This batch will often prove most serviceable should a dry, hot autumn set in, the thick growth shielding the bloom and young pods, and keeping the ground from parching, as when sown in rows. These will produce Beans until cut down by frost. Those who are this year trying the new climbing French Beans will find them of great value. This new race is certainly a great acquisition. With all late batches of Beans, whether of the runner or dwarf section, it is well not to postpone mulching until they are in a bearing condition. If done early and rich material used, the ground not only becomes thoroughly moist through repeated waterings over the mulch, but much of the nourishment is washed down for the roots to feed on by the time the crop tells on the energies of the plants.

**FRAME CUCUMBERS.**—The season having been so far favourable for the growth of these, plants got out in good time will now be yielding freely and will require plenty of support. Avoid over-cropping, even where profit is the chief consideration, as this will quickly tell on the plants and

bring about a premature collapse. Go over the frame once a week and reduce the fruits where clustered together, thinning out all weak growths and pinching the heads of strong forward shoots. Feed liberally for the rest of the season, closing moderately early, and giving the foliage a good steam bath on hot sunny afternoons. Attend to the admission of a little air early in the morning, a little given in good time, say, half-past seven, keeping the temperature from rising to such a high pitch during the forenoon. Cut the fruit as soon as a reasonable size has been reached, and place the stems in a vessel furnished with a little damp moss. This is preferable to water and the fruits keep much better. Keep in a cool, dark place. When going over the plants remove all male blooms, as these are only hindrances to a free and vigorous growth. Where fresh plants have now to be put out use a somewhat retentive soil, this being necessary at this advanced date, in order to retain plenty of moisture; make it very firm, and water well the day before putting out the plants. If any traces of spider are on the plants, syringe well with sulphur water previous to planting. A good sort for sowing for late frame use is Lockie's Perfection, it being of quick growth and an early and good fruiter, also of excellent quality. In fact this is a good Cucumber for all purposes. Duke of Edinburgh is also capital for frame use, though a much larger fruit than the foregoing.

J. CRAWFORD.

### FRUIT HOUSES.

**PINES—FRUITING PLANTS.**—The bright weather of the last few weeks will have brought the early fruits on rapidly, the Queens ripening more quickly than required. When fruits are wanted for special dates they can be retarded by removal into cooler structures, shading them during the hottest part of the day. Fruits of the Queen section that are colouring are not hurt in the least by removal to a cooler and more airy house. Matured slowly they are better flavoured and a glut of fruit at one time is prevented. Fruits fully ripe which are required to be kept some little time should be removed to a cool fruit room, kept dry, and in this condition will keep plump for some time. If cut they soon shrivel. It is best to remove the suckers before placing the plants in the room. Plants with ripening fruits should not be dried off suddenly, but be given sufficient water to keep them fresh. Many shifts can be made with plants approaching maturity during hot weather, as frames not heated or small pits can be used to retard well advanced plants, the fruit being kept clear of drip and given a free circulation of air. Plants with fruits swelling need liberal treatment and a moist atmosphere. The night temperature at this stage should not fall below 75° and 10° higher by day with air, closing sufficiently early to run the thermometer up to 100°, syringing all parts of the house to create a genial atmosphere, gently dewing over healthy plants which are fairly well advanced, but not filling the axils of the leaves full of moisture. Watering will require more attention for the next few weeks, as with plenty of sun the air will be drier and the plants require more moisture at the roots. If allowed to get too dry it is a difficult matter to get the soil saturated, and the fruits cease to swell, the green tops becoming elongated. Give food freely in the way of liquid manure or guano water. Strong plants making a lot of growth should not be fed; indeed, they require quite the reverse treatment, keeping them drier for a time. I have found it beneficial to remove such plants into a lower temperature to arrest growth. Any plants of the late summer fruiterers that may have been retarded should now be placed in the fruiting division and treated as advised for plants swelling their fruits. Strong plants from last season's suckers of the Smooth Cayenne section or Charlotte Rothschild pushed on now will furnish nice fruits at a season they are much appreciated, as if they show fruit during the next few weeks they will be valuable for winter dessert.

**YOUNG PINES.**—These will include those placed in fruiting pots recently. More care will be necessary with these, as having fewer roots, excessive moisture will soon sour the soil and a sickly growth follow. With free ventilation there should be no lack of moisture if the plants are robust and filling their pots with roots. The bottom-heat for plants at this stage should not fall below 85°, and the temperature of the house may range from 70° to 80° during the day, with 7° to 10° lower at night, maintaining a moist growing atmosphere and well syringing all parts of the house. If syringed overhead too freely or kept too moist, an excess of sucker growth is encouraged, and the plants will probably give small fruits. With the thermometer at present higher during the day in the open than the temperature advised, fire-heat from 9 a.m. till 6 p.m. is not required, but if the bottom-heat is supplied by hot water this should not be turned off. A sharp watch must be kept for sudden changes, reducing the air. Shading will be necessary in most cases; use a light material such as scrim canvas or netting, not a permanent shade, which is most injurious. Young plants less advanced may at this season be grown in temporary structures or frames if a regular bottom-heat of 70° to 80° can be given. If there is not much top-heat cover the glass with mats on cold or windy nights to keep up the warmth, and in such cases less moisture must be given, less syringing and early closing being resorted to.

**POTTING SUCKERS.**—This will be the most pressing work for the next few weeks, as most of the early Queen suckers will be fit for potting ere this. I do not advise wholesale potting, as it is much best to do the work piecemeal as the plants are cut or cleared of the fruit; and should the suckers be small, it is much better to leave them for a little longer on the old stools. The soil for the young stock should be prepared in advance, using good sound fibrous loam, with a small portion of bone meal. Give ample drainage and pot firmly, having the soil sufficiently moist. The size of pots varies according to the strength of the plant; 6 inches to 8 inches are the usual sizes. If the suckers are strong most of them may be given a 7-inch or 8-inch pot. Clear the suckers of the bottom leaves only, taking away the portion that would be buried in the soil, as the less trimming done the better. To detach the suckers from the plants give a slight twist, not using a knife. Plunge in a bottom heat of 80° to 90° and as close to the glass as possible, with ample shade during the hottest part of the morning, removing early and closing before the sun leaves the house or pit. Lightly damp overhead at closing time and water when required, but only sparingly till the roots get round the sides of the pot. If the soil is moist little water will be required till the plants are rooted.

**MELONS.**—The season has been most favourable for these fruits, but there is still a necessity for continued warmth in the hot-water pipes, as there are times when the temperature is much lowered owing to rain and other causes. From this date canker will be troublesome, especially so with crowded plants in old houses without means to keep up the temperature. If canker appears keep the plants drier, and dress the affected parts with fresh quick-lime, sulphur, and finely powdered charcoal. Closely watch ripening fruits and remove them just as the stalk is cracking. The thick-skinned varieties are much better flavoured after having been cut from the plants for a few days. Melons at the final swelling stage need more care in watering, as excess causes them to crack badly and they do not keep well. Manures must be withheld, as the flavour is so quickly impaired. Plants with fruits just set and at later stages will also need more syringing overhead in such seasons as this. I never knew red spider more troublesome. Though a free use of the syringe will keep down the pest, it often makes too much headway, when sponging or covering the leaves with sulphur is the best remedy. Painting the pipes also with sulphur and milk or a little oil to make it adhere, and heating them late in the day will check both mildew and red spider. Black fly if troublesome is

also difficult to get rid of, and the plants suffer if smoked too strongly. Syringing with tobacco water will be the safest remedy, shading for two or three days after doing the work. There should be no lack of food to plants swelling their fruits, liquid manure being the best at this season. Top-dressing should not be omitted, giving a small portion of bone meal in the compost.

**FRAME MELONS.**—Good fruit will this season have been secured without fire-heat, but to get these every ray of sun-heat must be retained by careful ventilation and early closing. In previous notes I suggested raising the growths by means of a simple trellis or support. This gives a free circulation of air round the stems, and the fruits, being near the light, do not crack and are much better shaped. With the plants in movable frames and manure as the heating agency, it is well to renew the outside linings frequently. The warmth in the frames can be retained by covering the glass at night with mats. In watering much care will be required now, as the manure retains moisture freely and less syringing overhead is necessary. Watering should be done sufficiently early in the day to allow the leaves to get dry before nightfall. The stems should be kept dry and the lateral growths not required removed.

**LATE MELONS.**—In some gardens late Melons are required, and, though often condemned as poor in flavour, I have had Melons in October as good as could be desired. Much depends upon the season and the means to grow the fruits. Like early fruits, they need more than ordinary care to get perfect finish. Now is a good time to prepare for late crops, as if the plants make ample root and top growth there is less difficulty in finishing the fruits. Pot culture may be resorted to with advantage where there is any difficulty in giving the roots the treatment desired, as then fermenting materials may be used. The roots of plants in pots being more under control, can be fed, the setting is more readily done and growth is kept more confined, allowing light and air to circulate freely round the plants. Late plants in pots or restricted spaces need more liberal feeding. Bone meal or spent manures may be used to lighten heavy clay soils. In sowing at this season raise the plants in frames as close to the glass as possible, a sturdy growth from the start being essential, and in planting be careful not to injure the stems, or canker will be troublesome.

G. WYTHES.

### KITCHEN GARDEN.

#### PEAS IN DRY SOILS.

THE Pea crop this season has had a fight for existence in poor gravelly soils. In many places I note insects are attacking the bine, and, should rain fall in quantity, mildew will soon finish the work of destruction, and the late crop will be a poor one. Gardeners are often to blame in a great measure for failures, as the Peas are often sown so thickly that it is impossible for the plants to obtain the necessary food, especially in such seasons as we are experiencing. It may be said, why advise thin sowing when, perhaps, half the seed does not germinate? Most growers can at a glance tell if the seed is good. I admit it is not always as well selected as one could wish, but, from my own experience, I should say there are few vegetables more troublesome to rogue. To get a true stock is more difficult than many imagine. I was much amused the other day at being asked to explain the cause of failure of some rows of Peas sown on a sloping bank in soil which had not been manured for three years. The questioner stated that the seedsman was at fault; whereas the crop germinated well (indeed, too well); as if only half the seed had

come through the soil the other half would have done better. I admit sowing on banks may be a gain for the earliest crops, but such positions for tall Marrow Peas are not suitable, as the moisture when given all runs to the lowest point. It is well known how well Sweet Peas thrive when sown thinly and in rich soil; whereas when crowded the flowers are much smaller and soon over, and anyone would think the produce a different strain altogether. Some Peas may not be suitable for the soil, as, for instance, when I lived in the midlands, Veitch's Perfection was the best Marrow Pea, and grown in large quantities from June till September; whereas now in a light soil on gravel it is a bad cropper and not worth sowing, so that it is well to take varieties into consideration and grow those which do thrive.

#### VARIETIES.

A few words as to varieties may not be out of place. I do not consider the small white kinds, such as Extra Early or Early Sunrise, pay for growing, as we have now so many really fine varieties and of equal earliness. Gradus is a very fine early Marrow and a great advance on the older types. This in a dry season on a sloping bank was fit for use in twelve weeks from time of sowing and not protected in any way. This is one of the late Mr. Laxton's hybrids, and one he told me he considered the earliest and best of the many he had raised. With me it produced very heavy crops, in addition to being early and of good eating quality. Another Marrow variety which will doubtless come to the front is Sutton's Seedling Marrow-fat, very dwarf—this season only 1 foot high—pods containing six to nine Peas. This I grew for the first time this season, and it was very fine, doing well in spite of the drought. As a forcing variety in pots it cannot be excelled. Another good dry weather Pea is Stratagem, a very fine flavoured kind and heavy cropper. It is a midseason Pea and invaluable in such summers as this. Daisy, a second early, 15 inches to 18 inches high, is a valuable new Pea, very free and noted for its good quality. This sown on light soil early in March follows Gradus and other first early kinds, one of its parents being Stratagem. For July cropping my best variety is Veitch's Main-crop, a very fine vigorous variety, pods large and the growth not too tall. This year it promises grandly.

G. WYTHES.

**Turnip Cardinal.**—This variety is distinct from most others, having a deep cardinal colour, which not only appears on the top, but also covers the whole root. Of course, I do not recommend it on account of its novel colour, but as a good variety in hot seasons and as a variety that does well in most soils. The Cardinal is of medium size, flat, with very short top, and of fine table quality. It is one of the best varieties I have yet grown on hot, dry land, not running to seed like some early kinds, and being quite sweet and solid at the time I write. It has been fit for use since the end of May. The Cardinal has a strong tap root, this doubtless protecting it from drought, and having thick, spreading foliage the root is shaded. I have not tried it for late sowing, as Red Globe is the variety I rely on.—G. W.

**Lettuce in hot weather.**—Those who require Lettuce in quantity have to adopt various means to produce good material for every-day cutting, and the usual system of planting out of the seed beds cannot be carried out, as the plants in light soils suffer badly in hot weather. The plants are often sown much too thickly and do not lift readily; indeed, the tap root is generally broken when removing, and the plants get such a check

that they require much attention in the way of shade and moisture to get them into a growing state, and often when they make a start they bolt. The best way to secure a long succession is to sow very thinly every three weeks in rich land, and my plan is to drop half a dozen seeds from 9 inches to 1 foot apart in flat drills 3 inches deep, and when the seedlings are above the soil to thin to the strongest; the thinnings may be planted on a north border. The Celery ridges are very good for summer sowing. In summers similar to the one we are now experiencing planting out is out of the question, as so much time is taken up in watering and looking after the crop. As Lettuce of first-rate quality is more appreciated in hot weather it is well to give ample attention, and thus secure constant supplies. For midsummer I find none equal to a good type of Cos, such as Superb White, a large variety, which folds in closely and is a long time before it runs. The older Ivory's Nonsuch is still a very fine dry summer Lettuce and of very good flavour. A great favourite of mine is the Mammoth White or Balloon Cos, a grand summer variety with large firm hearts, and one of the very best of the newer types. This I have grown since 1893. Those who do not sow so often as advised, and have unsuitable soil or little moisture, would do well to use cow manure instead of other kinds. It is a valuable hot weather manure, retaining moisture longer. It is also advisable to sow on the flat, and for July supplies under a north wall.—G. W. S.

#### EARLY CABBAGES.

I was surprised to read "A. D.'s" note on the dearth of early Cabbages in the London district, as I never had a more satisfactory lot than I have this season in this garden, and not a single runner amongst them. I rely on two varieties for early cutting, these being Ellam's Early and Mein's No. 1—the former, as is now well known, being a neat little Cabbage of excellent flavour, and Mein's No. 1 of larger growth, but equally as early. Mein's No. 1 can be cut either as a small early, or, by waiting a week or two longer, as a later and larger Cabbage. This is certainly an advantage, for whereas Ellam's would burst if left too long, Mein's No. 1 would go on increasing in size for a considerable period. I should think this variety would make a good market Cabbage. As to its hardiness there cannot be any question, and to my mind it supplies what "A. D." considers to be wanting. If "A. D." could induce any of his market gardening friends to give this variety a trial, I do not think they will be disappointed. For a private garden a good plot of Cabbage is of considerable value, as by a little judicious management a succession of Cabbage sprouts may be had without any trouble, beyond keeping the ground free from weeds and decaying foliage. Ellam's, however, is not a good variety for turning off an abundance of well-flavoured sprouts, but Mein's No. 1 is. The best variety I find in this respect is the Nonpareil, and Enfield Market is another excellent variety for secondary cropping. To encourage a good succession of small heads, care must be taken in cutting only to take the centre heart, leaving as many of the lower leaves as possible, as from each leaf a small head will form. As long ago as I can remember it was an old custom after the head was cut to trim off the leaves and cross-cut the stump. Leaving as many leaves as possible is the best plan to follow so as to secure a succession of sprouts. Large old heads of Cabbage are liked by nobody, being hard, strong, and yellow-hearted, so much the most profitable plan is to cut off the heads so as to encourage the later growth.

There is also much in the selection of suitable early varieties to escape the evil of bolting. Early sowings of such varieties as Enfield Market and Nonpareil will surely end in the greater bulk bolting. Ellam's Early and Mein's No. 1 are practically exempt from this evil. For the earliest batch and for this district I find the middle of July a suitable time for sowing. As

seasons vary so, it is as well to have two strings to your bow, and as a safeguard against any emergency another sowing is made at the end of the month. It is quite as much an evil to be too early for the season as too late. It can easily be seen when the time comes for planting whether the plants are too large and forward to winter safely. The seeds must be sown very thinly over a good extent of ground according to the quantity of seed to be sown. Crowding the plants into a square yard or two of space will surely spoil them. The most suitable time to sow Enfield Market and Nonpareil is from the 16th to the 20th of August.

A. YOUNG.

#### LATE-PLANTED WINTER VEGETABLES.

It sometimes happens that late-planted Broccoli, Borecole, Savoy, and such like prove nearly, or quite as serviceable as any got out much earlier. Especially is this the case when the plants have also been raised late, or prepared on poor ground quite in the open. Those raised early and thickly in the seed-bed—the positions being sheltered and the soil fertile—are apt to become very large if not crowded, or else, if crowded, very leggy, neither class of plants moving well. Starvelings from the open fields or poor allotments, if drawn a few hours after either a soaking rain has fallen or a good watering has been given, take to their fresh quarters surprisingly quickly, flagging but little in quite the hottest weather. Very leggy plants and any over-grown are scarcely worth the trouble of planting, or, at any rate, are very inferior to those raised late or sturdy in character. Early and second early Potatoes will in far too many cases prove a light crop. Two or three, or, it may be, five or six fairly large tubers are found at the roots of most varieties, and numerous small ones not much larger than Peas. If they are left undug in order to give the latter a chance of growing larger, there is every likelihood of the large ones "growing out," and probably an attack of disease crippling the crop generally. Better, therefore, lift at once and crop the ground closely with winter vegetables. If justice has been done the Potatoes, cleaning, levelling over, and firming the ground is all the further preparation needed for the successional crops. Many Peas and Beans will also come off the ground early this season, and, though late in commencing to ripen, Strawberries have also failed quickly, this, where an early clearance of old plants is made, admitting of winter vegetables being planted in close succession. There ought to be no ground lying idle in a kitchen garden unless particularly wanted and undergoing special preparation, say, for winter Spinach. At the same time it should be remembered that vegetables generally, and the Brassica family in particular, are great exhausters of fertility, and if we crop closely and heavily we must follow the example set by market growers, that is to say, manure heavily. Grossness is objectionable in most winter vegetables, but I would yet dig in manure for them rather than attempt to produce them on very poor ground.

In order to have a full, heavy crop of Brussels Sprouts, the bulk of the plants of these ought now to be growing strongly where they are to remain, though I have known batches of plants put out as late as the middle of July give excellent late crops of sprouts. This late planting is most desirable where the soil is not equal to sustaining plants throughout a full season. Borecole late planted will at least give a fairly strong top and some few greens, but if the Asparagus Kale is planted or even sown now where it is to grow Spinach fashion, a capital supply of suc-

culent greens will be had next April, May and June. The latter is one of the hardest greens and may be either planted or thinned to a distance of 12 inches apart in rows 2 feet or rather less apart. After the experience of the past winter we ought to find as much room as possible for the hardy Borecole or Kales, notably the Cottager's Kale and the Arctic Kales, as all these did good service and can always be depended upon. Not so Broccoli. I suppose we must always try to grow some of these, but their culture must be regarded in the light of a lottery. Either there are more Broccoli available than we know what to do with, or else there are too few or none to be had after the early autumn varieties are over. Veitch's Autumn Protecting Broccoli I consider should be much the most extensively planted, and any put out now on somewhat rich firm ground would most probably be available for storing under glass in November, hearting in some time in January or February. It must always be borne in mind that it is one of the least hardy Broccoli. Other varieties can be prepared to withstand a moderately severe winter. Ground newly cleared of Peas, Beans and Strawberries is a good site for these. Holes may be formed with the aid of a crowbar, or, better still, drills be cut with a heavy hoe and filled with water (twice if necessary), after which it will be possible to plant with either dibber or trowel. The rows may be at the same distance apart as the centres of the spaces between the late rows of Strawberries, and the plants 2 feet apart in the rows, as there is not much likelihood of their overgrowing each other. On the contrary, they will be short-stemmed, compact, and, to a certain extent, frost-resisting. I do not promise anyone following this advice, or who plants late on solid ground, large hearts next winter or spring, but he ought to have some quite large enough for most tables. Late-raised and late-planted Broccoli are usually hardier than any already growing strongly where they are to remain are likely to be, and if only leggy, early-raised plants are available, do not sink them in deep holes up to the leaves, but instead of this plant in a sloping direction, all the stem being covered with soil.

Now is a good time to plant Chou de Burghley extensively. Planted early on rich loose ground, a coarse, next to useless crop is the result. We want hearts of the size of Ellan's Dwarf Spring Cabbage, and during November and December they would then be fully appreciated. In some seasons they pass through the winter uninjured, the hearts remaining sound and good for a long time after they are fit to cut. Savoy's, again, are of little value when overgrown. Who cares for the great coarse hearts grown in so many gardens? Very few, probably, or otherwise fewer would be left to rot on the ground. Those of the Tom Thumb type are by far the best in point of quality, and next to these I place Dwarf Elm and Gilbert's Universal, the Green-curl'd and Drumhead being grown principally because they heart in later.

W. I.

**Veitch's Earliest Marrow Pea.**—There is little excuse for growing Peas that are deficient in flavour on account of their earliness, as some of the more recent introductions in the early section are quite first-rate in this respect. The variety named above, which I am growing for the first time this year, has pleased me much, as its high quality is most marked, the Peas being exceptionally sweet. Probably it is not such a heavy cropper as some of the early kinds, but it has given a fair crop in spite of the drought which had continued for so long until a day or two ago, and which tended to shorten the bearing season of

early Peas. One of its good qualities is that it hangs for a long time after being fit to pick without getting hard or losing its sweetness and deep green colour. As a proof of its earliness I sowed in an open quarter on March 11 and picked a peck of good Peas from a row about 15 yards long on June 11, just three months from sowing. Altogether, I think it a worthy companion to that excellent variety Chelsea Gem. The Peas individually are not large, but the flavour is equal to that of the best Marrowfat kinds.—J. C. TALLACK.

**Walcheren and Early London Cauliflowers.**—I have been much interested in the recent correspondence on the merits of these two Cauliflowers. I must throw in my lot with those who maintain that Early London is both distinct from and earlier than Walcheren. I have grown Cauliflowers for many years for early work, and have always considered these two varieties distinct, Early London being the first to turn in by some ten or twelve days. Lately, however, I have been so annoyed by buttoning in Early London that I have decided to abandon its culture. I think the fault lies in the bad stocks of seed owing to the great demand for this particular variety. Walcheren is a grand Cauliflower, and for successional work right through the summer I know of none to surpass it.—J. CRAWFORD.

**Planting green crops.**—Planting Cabbages, &c., will have been retarded owing to the drought, and unless special care be taken of the plants of the Brassica tribe in the seed beds, they will be much drawn and deficient of fibrous roots. It is now full late to advise transplanting or pricking off into lines to get dwarf plants with plenty of roots. The plants, if at all crowded in the seed-beds, get more injured at this date than earlier, as being much larger each one is fighting for existence, with the result that all but a few outside plants are crippled. To avoid this it is well to plant out though we have a tropical summer, as the longer the work is delayed the more the plants suffer. Much the best results are secured by planting medium-sized plants with ample roots, as the larger ones are so much affected by lifting. It may be asked, How can one plant in such a season with the soil like dust? My remedy for such is deep drills, these being filled the evening before planting with water; then plant and water when required at night. This will be far better than allowing the plants to run to waste in the seed bed. When we do get the much-desired rain, the plants, with the great warmth in the soil, will soon make up for any delay. By making drills a man with a large water-pot can go along each quickly. It is surprising how long the drills retain the moisture when once well soaked.—G. WYTHES.

#### EARLY CAULIFLOWERS.

MR. WYTHES' most interesting article (p. 456) will do something to clear up the confusion that now obtains with regard to the different varieties of Cauliflowers and their synonyms. Personally I beg to thank him for it, and will, if I can get it true, follow his advice to grow the Dwarf Mammoth Erfurt when sowing this autumn. My experience with the Erfurt has been somewhat similar to that of Mr. Wythes with the Early London in that the seeds which I obtained on two or three occasions must have been from an inferior stock, the heads produced being loose and ungainly, and this decided me to stick to a good strain of Early London. On the other hand, what was sent to me as Snowball was too small for sale, though valuable to provide a few early dishes for private use. In the Chiswick trials Snowball and the Erfurt varieties were classed together. This trial of varieties at Chiswick loses something of its value, as Mr. Wythes says that it was not used as a test of earliness—an important point with Cauliflowers when we remember that their value is greatly enhanced by their earliness, as it is not unusual for prices to drop 4s. or 5s. per dozen within a week, or directly Peas come into the markets in quantity, and it was this that I had in

my mind when writing my earlier note on the subject. I am pleased to see that Mr. Young supports my view that Early London is earlier than Walcheren. It has proved so with me each year. Walcheren, as I grow it, besides being later, runs taller and proves a most valuable kind for succession, though if seed of The Pearl was a little cheaper and not quite so scarce, I should prefer this to all others as a second early. The method of treating autumn-sown Cauliflowers adopted here is to sow a little later than is generally recommended, leaving the young plants in the seed bed until sharp frost threatens. They are then lifted and replanted about 6 inches apart in good soil in one of the pits used for growing Cucumbers in summer, and here they winter very well, losses from cold or from early buttoning being rare. A mild time when the ground is in good condition early in spring is chosen for planting, and no hand-lights are used for protection. I choose a warm border under a south wall for the plants and protect with a few twigs of Spruce or Laurel. This year I put out in this way about 280 plants on March 20, and these have been most successful. In a colder and heavier soil I prefer potting up the plants in autumn, but they lift well with me and take readily to the light and sandy garden soil. I should be glad to see from any of your readers notes that may help to clear up the confusion which there is now as to names and synonyms.

J. C. TALLACK.

## ORCHIDS.

#### NOTES ON ODONTOGLOSSUMS.

If it were possible to ascertain the number of plants under cultivation belonging to each genus of Orchids, these would probably be far ahead of all others. The numbers of such as *O. crispum* would be simply overwhelming, and the reason of this is not far to seek. Being so thoroughly at home under cool treatment and so beautiful when in blossom, they are naturally much sought after by all classes of Orchid growers, and as the demand is so heavy, nurserymen and others engaged in importing find it to their interest to seek such plants. The risk of having the plants left on hand is reduced to a minimum, and this is no small matter to those who have to stock them. The majority of *Odontoglossums* are not by any means constant in their time of flowering, but this is an advantage rather than otherwise, as it enables anyone with a fairly good stock of plants to keep up a fine display over a long season. The first six months in the year are the principal *Odontoglossum* season, though many of them are still in full beauty, and others will carry on the display until the end of the year. It is this latter section that I am thinking of more especially just now. A very beautiful kind, quite distinct from all of the *crispum* and similar types, is

*O. MICHONENSE*, the oldest species in cultivation, and a remarkably free-flowering plant. This when in good condition frequently produces spikes over 2 feet in length, bearing many flowers, each about 1½ inches across. These are of varying shades of yellow on the sepals and petals, with brown or purple spots, the lip lilac or rosy pink, heart-shaped, and irregularly frilled at the edge. This is of very easy culture, and although liking rather more heat than the *crispum* set, is not fastidious in this respect. It is a native of Guatemala and Mexico, and was introduced about sixty years ago. The var. *superbum* is said to be a greatly superior form, with darker coloured flowers.

*O. GRANDE* is the largest flowering in the genus, and one of the showiest and best known. This is one of Mr. Skinner's introductions from Guatemala. The blossoms are produced on erect

scapes, each bearing from three to eight, these being upwards of 6 inches across. The sepals and petals are bright yellow, transversely barred with rich chocolate and brown, and they have a shiny, varnished appearance. The lip is whitish with brown lines and spots. The warmest and shadiest position in the Odontoglossum house must be given *O. grande*, and it also delights in a rough, open compost. The pseudo-bulbs and leaves seemed more than usually attractive to slugs, these pests attacking the young growing shoots with great avidity, frequently causing a great amount of mischief. *O. grande* usually rests awhile after flowering, and it ought not to be excited until it breaks naturally, unless it is desired in flower earlier than usual with a view to succession. If kept in a temperature of not less than 52° during winter and induced to make a free growth during summer, it never fails to flower freely during late autumn or early winter. *O. grande superbum*, *O. g. magnificum*, and *O. g. pictum* are all good, well-marked varieties of this favourite Orchid.

*O. INSLEAYSI* greatly resembles *O. grande* in habit and manner of growth. The flowers, smaller and produced earlier in the season, are yellow in ground colour, blotched with red, more especially on the sepals and petals. The variety *leopardinum* has a very richly coloured lip, bright yellow with crimson dots around the margin, the variety *splendens* being a rare and lovely kind with large, richly-coloured flowers. The type is a native of Mexico, introduced about fifty years ago. Both this species and

*O. SCHLEPERIANUM*, which it greatly resembles, will thrive with *O. grande*; indeed the latter has been described as a variety of this species, viz., *O. grande pallidum*, but it is usually known by the above designation. The flowers are very pale yellow, the sepals and petals being blotched and barred with purple, the lip small and marked with brown. This was introduced from Costa Rica in 1836.

*O. URO-SKINNERI* was sent by the gentleman whose name it bears from Guatemala in 1854. It is a strong-growing, easily-grown plant now in flower in several collections. The blossoms are each 3 inches across, the segments yellow blotched with brown, the lip rosy purple and white. These are produced on tall spikes, and last a long time in full beauty. It requires abundance of water at the root, good drainage, and a cool moist atmosphere all the year round.

*O. HASTLABIUM* is usually in flower during August, and therefore often used for exhibition. It produces a succession of flowers upon the upright branching spikes, these being very fragrant and upwards of 3½ inches across in the best forms. The sepals and petals are creamy white overlaid with brownish purple, the lip purple at the base, pure white in front. This requires more heat than any other species, being found naturally at a low elevation in New Grenada. The pseudo-bulbs and leaves of this species are very pale green, the latter broad and sometimes as much as 15 inches long. Introduced in 1843.

Besides the above, many of the varieties of *O. Rossi*, *O. maculatum*, *O. Edwardi*, *O. gloriosum*, and others occasionally flower in the autumn, so that there is no lack of variety where a number of plants is grown. Great care is necessary with them all while in bloom and afterwards, and it may be taken as a general rule that from a fortnight to three weeks is quite long enough to leave the flowers on the plants, many of them lasting quite another fortnight when cut. R.

**Cypripedium Sedeni.**—Although of hybrid origin, this lovely plant is, fortunately, plentiful enough. It is extremely popular on account of its free-flowering habit and handsome appearance. The leaves of *C. Sedeni* are each about 15 inches in length, deep green, gracefully arched, and on healthy plants very attractive. The scapes rise from the centre of the growth, producing many

flowers in succession. These are each about 3 inches across, the sepals being whitish, the petals twisted, bright rose, margined and sometimes streaked with white. The pouch is round, crimson in front, the throat white, with crimson spots. It belongs to the *Selenipedium* section of the genus. The plants may easily be kept in a thriving condition by ordinary care, and, being a vigorous-growing plant, it is easily propagated. Indeed, it occasionally throws up a kind of upright rhizome with a growth at the end, and advantage may be taken of this to increase the stock. The best time to repot *Cypripediums* is in early spring, before the plants commence to grow. They may, however, if in bad condition at the root, be safely potted at any season, provided they receive careful attention afterwards. Such plants must have all sour and rotten portions of the compost removed, and, after washing the roots thoroughly in tepid water, cut away all that are decayed and allow them to dry before repotting. The compost best suited to its requirements consists of fibry loam and peat in equal proportions, adding a plentiful sprinkling of small crocks and charcoal, with enough chopped Sphagnum to make the mass spongy and light. The rough drainage is essential, as a full supply of water is needed while growing. Spread the roots out carefully and work the compost among them, not raising the plants above the rim, as is usual with most Orchids. *C. Sedeni* is a restless Orchid usually, but resting can be induced by lowering the temperature a little during winter. It is not necessary to dry the plants at the root, as this serves only to weaken them. The *Cattleya* house temperature suits it well while growing, and after repotting, the plants may be dewed over with the syringe until the roots are taking to the compost, when they will need watering almost daily.

## ROSE GARDEN.

### ROSE NOTES FROM COLCHESTER.

The lamentations that went up as the severe frost gave way might have led us to suppose that there were very few Roses left in the land, but the reverse is quite the case, and when calling at Mr. B. R. Cant's recently we found his noted Rose fields gay with colour. Of course, losses have been general and great, more so as regards old plants, but the dormant buds of last year's budding stood the cold, and now again we see the familiar nursery lines with very few blanks. There was no prettier picture in Mr. Cant's nursery at the time of our visit than the hedges and fences covered with the old cluster Roses, and it is a pity that they are not more used in this way where pretty dividing lines are wanted. Our chief object, however, was to see what was new, and although no notable addition to the great Rose family can be chronicled, several kinds of promise were seen in good form. Among H.P.'s, Mrs. Sharman Crawford and Marchioness of Downshire are both distinct with full, well-formed flowers in shades of pink, those of the latter variety borne on very erect strong shoots. Marchioness of Dufferin, also pink and possessed of a good sturdy habit, is a new Rose of considerable merit. *Clio*, the new blush Rose sent out by Mr. W. Paul, is finding favour, and deservedly so, for whilst it is up to exhibition form, it has the most essential quality of robust growth, making large plants that will cover themselves with fine flowers. It is a most valuable addition, as it flowers freely, opens well, and in its soft-blush white shade gives us a colour by no means common in this class. *Marquise de Litta* (Pernet and Ducher, 1893) Mr. Cant thinks a promising new Rose. It has a large

petalled flower, of a rosy cerise colour. Mrs. Harkness, or Paul's Early Blush, was conspicuous with many flowers, and will certainly make a gay garden Rose; whilst Jeannie Dickson, though not now considered as new, is a recent kind that may be highly recommended for planting in groups in the garden. Margaret Dickson we noted carrying fine flowers on some old cut-back plants, whilst the growth was most robust.

Among the Teas the American variety named Golden Gate had some splendid flowers, and is clearly a worthy addition if it maintains the fine form in which we saw it. The name, however, is singularly inappropriate, as there is nothing of a golden character about it. It is of a pale cream colour, shading to deeper yellow at the base of the petals, but flushed with faint pink at the edges. *Corinna* was easily distinguished from the rest by its distinct colour, and it is very free-flowering. *Medea*, too, seems to be gaining favour. *Kaiserin Augusta Victoria* (Hybrid Tea) is a grand Rose, with all the refinement and beauty of a true Tea, carrying full, shapely, cream-white flowers on strong shoots. *Mme. Pernet-Ducher*, of the same class, is a Rose to plant for effect, the plants covering themselves with great clusters of bloom, the buds rich nankeen-yellow, the expanded flowers nearly white. Of quite an opposite colour is *Marquise de Salisbury*, a new kind much praised last year, but again justifying all that was said in its favour—a perfect marvel of profuse bloom. The little *Polyantha* varieties have come through the winter safely, and although free at all times, we never saw them promising a more abundant bloom than here, the plants being invisible beneath their mounds of buds and tiny flowers.

**Budding** will now be general, and we must not fail to work the hedge Briers as the shoulders come ready, as the present dry season is already causing many of them to hang or bind. When I wrote last it promised rain here, but none fell, and we are now very much parched up, more so than in 1887 or 1893.—RIDGEWOOD.

**Rose W. A. Richardson.**—Your note (p. 429) on this Rose is opportune. In this neighbourhood many fine plants of it are to be seen growing up the front of cottages. I never saw any Rose bloom more freely, and this season the leaves can hardly be seen for flowers. It requires so little pruning that it is just the Rose for cottagers to plant; another point in its favour is the easy manner in which it grows from cuttings.—E. M.

**Rose Renoncule.**—Away from cottage gardens and nurseries, how seldom do we see this old Rose. It is one of the best of the climbing section for covering a wall, fence, arch, or pillar. On the front of a cottage in this village at the present time a grand plant of it is now in bloom. It is fully 20 feet high and quite as much across in the widest part. The flowers are after the style of those of a *Ranunculus*—white tinged with pink, hence its name. The dark green foliage with the red tinged bark of the branches enhances its value. It grows freely from cuttings.—E. M., *Swanmore Park, Bishop's Waltham*.

**Cluster and single Roses.**—Few gardens contain even a tolerably good collection of these Roses. Although the beautiful Hybrid Perpetual, Tea and Noisette Roses are so generally cultivated, there is yet room for a representative collection of these. In a collection I lately saw I noted the following: the Blush China, bright pink, singularly beautiful; *Harrisoni*, with its fine golden yellow flowers, most telling in a mass either upon the plant or in a vase, and *Brennus* (belonging to the Hybrid China section), brilliant crimson in colour, reminds one of that charming H.P. Marie Baumann, a really fine pillar Rose. Rampant, pale pink, has neat little blooms freely

produced in clusters; and Red Damask is very showy, semi-double, reddish crimson. Village Maid resembles York and Lancaster, except that the stripes are much darker: Dundee Rambler, blush white, well represents the Ayrshire type of Rose; and Fellenberg, with clusters of rosy red blossoms, is a most charming variety. Mme. Planter bears pure white blooms in large clusters and is suitable for pillars, but is, perhaps, better described as a bush. Microphylla, the single white form of the curious prickly-hipped Indian Rose, is pretty; likewise Ruga, one of the Ayrshire section, of a pale flesh colour and very fragrant. Felicite-Perpétue is well known, and Vivid, crimson, is a capital pillar Rose. Waltham Climber No. 1, with rose-coloured blossoms, is a free, bright kind; and Sweet Brier Lady Penzance is one of the best of the new Sweet Briars, the colour copper, with a peculiar metallic lustre and bright yellow at the base of each petal.—E. M.

**Rose Crimson Rambler.**—At Gunnersbury House this Rose is considered well worthy of a place in the conservatory, and Mr. Hudson grows it to perfection. It is suitable for pillars or for clothing the bays, and in either case must be grown very strongly in order to have great sprays of bloom, or such as can be cut for large vases in abundance. It is a summer Rose, and Mr. Hudson after the flowering period is over cuts back the wood to below the flower-breaks, thereby causing the formation of the requisite strong growth for flowering the following season. This Rose also succeeds admirably in pots.—I.

**Rosa rugosa Blanco de Coubert.**—This is a charming variety of the old *Rosa rugosa*, in which the blossoms are of that beautiful pure satiny white common to *Rosa rugosa alba*, but the flowers of this newer form are double, or, perhaps, by comparison with many other Roses, semi-double would be the best expression to use. The blossoms are certainly very charming, without any suspicion of lumpiness. A great deal of the value of *R. rugosa* is owing to the fact that, left to itself, it will form a handsome bush and soon attain considerable dimensions by reason of the sturdy suckers, which are pushed up so freely. These newer varieties are, however, generally grafted or budded, so that they cannot increase in the manner common to this Rose. Though plants on their own roots are, of course, preferable to others, I have seen very good results attained in the case of the single white variety (when it was scarcer than it is now) by layering the shoots directly they were long enough, and after that allowing them to remain untouched. The result was that each rooted layer pushed up suckers of its own when sufficiently strong, and in this way a bed of the white variety on its own roots was established.—T.

**Hardiness of Tea Roses.**—Now that my Tea Roses are in full bloom and better than I have had them before, I should like, in order to encourage others, to say that though the glass, which is alongside of them, fell one night to 2° and many nights to 7° and 8°, out of about 100

dwarf Teas, including even such tender kinds as Niphotos, Devoniensis, and Comtesse de Nadaillac, I only lost two plants. They are mostly grown on beds raised at planting some 2 feet, and now standing 1 foot above the level of the lawn, and had no other protection but a very heavy mulch of manure. The whole, including the hardest, Mme. Lambard and Marie van Houtte, &c., were when pruned to the green wood almost invisible over the mulch, which was mostly left on the beds for another month or more, but all are in bloom or showing good buds, and many have very long shoots. They were most of them exposed to the full blast of the north wind off the hills, but rather protected by the house, &c., from other quarters. I have not been much troubled this year by either aphids or caterpillars, but, unfortunately, my few Hybrid Perpetuals have at this

planted about two years I had occasion to build on that side of the house a tile-roofed verandah some 5 feet wide and without any light overhead, and also paved with tiles, leaving only a very narrow border against the Rose trees. As the trees grew I carried the long shoots across overhead, up under the eaves, and thus on to the roof of the verandah, and I am pleased to say that they have for several years now been a great source of pleasure to me as June comes round, being each summer covered with hundreds of buds. Nothing could look much prettier than the Banksian the day the photograph was taken (June, 1894), each tiny shoot having its several fairy-like, pinkish white blooms and buds waving gently in the breeze. The Ayrshire is rather

Roses in a Surrey garden. Engraved for THE GARDEN from a photograph sent by Mr. A. Trower, Wiggie, Redhill, Surrey.

early season already some mildew. Crimson Rambler has proved exceptionally hardy, as the twelve feet shoots, trained over an open trellis through which the north wind howled, did not show the least sign of frost even to their tips, and every eye is now a mass of buds. Ophirie alongside was badly injured, as likewise an old white Cluster Rose. What suffered most were the plants on the lowest wall of the house, where the sun was so hot that there was a variation of temperature of 40° in a few hours. Several perennials which I have had here for many years have entirely disappeared.—J. R. D., *Reigate*.

#### ROSES ON A SURREY HOUSE.

The Rose trees shown in the engraving were planted on the south side of the house some ten years ago, one on each side of a French window, the one to the left being a white Banksian, the one on the right a white Ayrshire. After they were

later, and, as can be seen, was not in its full beauty. I am pleased to say that in spite of the severe winter neither of the trees has suffered to any great extent; this is no doubt owing to the protection they get from the verandah. The Rose trees growing up the pillars have since been planted, and are not yet up to the roof. As the two Roses under the verandah never get any rain, I occasionally give them some water, but the border is too narrow to give them any manure—in fact, they do not require any. A. TROWER.

Redhill.

#### SHORT NOTES.—ROSES.

**Single Rose Reine Blanche.**—This is one of the best single-flowered Roses, and in the bud state it is indeed charming, the ivory-white, bright carmine-edged shell-like petals peculiar in colour and most

pleasing. It makes splendid button-hole bouquets, as the buds are so long in opening.—E. M.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL ROSE SOCIETY.

CRYSTAL PALACE, JULY 6.

It would be almost unfair in such a season as this to contrast the exhibition of last Saturday with preceding ones, yet there were many more entries than we might have expected and good competition in some of the classes. The flowers were, however, rather small, and lacked the fulness and freshness that characterise Roses in an average season. Especially was this noticeable in the crimson and dark-flowered varieties, but the light coloured kinds were in many instances finely shown, notably Her Majesty, which received the medal for the best Hybrid Perpetual in the show in both nurserymen's and amateurs' classes, two fine flowers of great depth and superb finish being shown by Mr. B. R. Cant and Mr. E. B. Lindsell. The two medal Teas were also magnificent flowers of their kind, Mr. Frank Cant receiving the coveted award in the trade classes with a very fine flower of Comtesse de Nadaillac, and the Rev. A. Foster-Melliar in the amateur classes with a large, deep-coloured flower of Maréchal Niel. No new Rose appeared of sufficient merit to receive the gold medal.

#### NURSERYMEN'S CLASSES.

In the great class for seventy-two distinct varieties, one flower of each, there was again a very close fight between Mr. B. R. Cant and Mr. F. Cant, the noted Colchester growers, the former being eventually adjudged the winner of the trophy and first prize, but only by four points. The best varieties in this exhibit were Her Majesty (the medal bloom), Susanne M. Rodocanachi, Duke of Fife, Duke of Wellington, Captain Hayward, La Fraicheur, Marie Baumann, Etienne Levet, White Lady, Boildieu, Gustave Piganeau, Charles Lefebvre, Comte de Raimbaud, and Countess of Rosebery among H.P.'s. Luciole, Ernest Metz, The Bride, Mme. Cusin, and Maréchal Niel were the best Teas. Mr. Frank Cant's stand had some notable flowers; in addition to the medal Tea we noted Mme. de Watteville, Catherine Mermet, La Boule d'Or, Innocente Pirola, Captain Hayward, A. K. Williams, Gustave Piganeau, and Comte de Raimbaud. For forty distinct varieties, three of each, the position was reversed, Mr. F. Cant being first with a fine, even lot, and Mr. B. R. Cant second. The best flowers were Her Majesty, Horace Vernet, three good blooms of this rich dark Rose, Marie Baumann, Victor Hugo, brilliant in colour, Duke of Fife, Marchioness of Dufferin, Marie Verdier, Reynolds-Hole, A. K. Williams, Salamander, and Gustave Piganeau H.P.'s, and The Bride, Ethel Brownlow, Niphotos, and Comtesse de Nadaillac, Teas. For forty-eight distinct varieties, single trusses, another Colchester firm came to the front, Messrs. Prior and Sons being first, their stand containing noteworthy blooms of Lady Mary Fitzwilliam, Victor Hugo, E. Y. Teas, A. K. Williams, Reynolds-Hole and Merveille de Lyon. The second lot came from Southwell. For twenty-four distinct varieties (single trusses) Mr. J. Mattock, New Headington, Oxford, was first, his best flowers being Her Majesty, Reynolds-Hole, A. K. Williams, Gustave Piganeau, Ernest Metz, and Mme. Hoste. Mr. S. Tresider, of Cardiff, was second. For twenty-four distinct (three trusses) Messrs. G. and H. Burch, Peterborough, were first with fine fresh flowers, Her Majesty, Merveille de Lyon, Horace Vernet, Earl of Dufferin, Mme. de Watteville and Innocente Pirola being the best. Messrs. Prior and Sons, Colchester, were second. An extra class for exhibitors who only showed in the above classes was for eighteen bunches of any H.P., Hybrid Tea and Tea or Noisette variety. Messrs. G. Paul and

Son, Cheshunt, were first with excellent bunches of S. M. Rodocanachi, Abel Carrière, Alfred Colomb, Capt. Christy, Bacchus, Mrs. Paul and Etienne Levet. Mr. G. Mount, Canterbury, was second.

In the trade classes for Teas we missed the name of Mr. G. Prince, doubtless owing to the dry season. Mr. Frank Cant took premier honours in two classes, namely, for twenty-four distinct single trusses and for eighteen distinct, three trusses of each. The two exhibits had some lovely flowers, notably The Bride, Mme. de Watteville, Mme. Cusin, Souvenir d'Elise Vardon, Comtesse de Nadaillac, Ernest Metz, Ethel Brownlow, Edith Gifford and Maman Cochet. For eighteen Teas, distinct, Mr. J. Mattock was first with a fine box of fresh and lovely flowers, Mr. H. Merryweather, Southwell, Notts, being second.

#### AMATEUR CLASSES.

The leading prize for thirty-six distinct kinds, which carries with it the amateurs' challenge trophy, was deservedly gained by Mr. E. B. Lindsell, Bearton, Hitchin, with what was undoubtedly the finest stand of blooms in the whole show, a remarkable exhibit for such an extraordinary season. With every variety except one of high merit, it is hardly possible to single the best out for special mention. Her Majesty, the amateur medal bloom, was in this stand, and other fine flowers were those of Gustave Piganeau, Mrs. Sharman Crawford, Dr. Sellew, Mme. Haussman, A. K. Williams, Duke of Connaught, Souvenir d'Elise Vardon, Caroline Kuster, and Catherine Mermet. The Rev. J. H. Pemberton, of Romford, Essex, was second. Mr. Lindsell was again first for forty-eight distinct single trusses with another fine fresh lot, the second prize going to Mr. W. Drew, Uplands, Ledbury. For twenty-four distinct single trusses, Mr. J. Gurney Fowler, Glebelands, South Woodford, was first, and Mr. W. Boyes, Duffield Road, Derby, second. The Rev. J. H. Pemberton was first for twelve trusses of any Rose except a Tea or Noisette with A. K. Williams, Mr. H. V. Machin, Worksop, securing second place with Her Majesty.

The smaller growers again justified the changes that have been made to encourage them. Among growers of less than 2000 plants, Mr. W. C. Romaine, The Priory, Windsor, was first, his stand containing good blooms of Charles Lefebvre, A. K. Williams, Marie Baumann, A. Colomb, Innocente Pirola, and The Bride. The second prize went to Mr. A. Slaughter, Steyning. For eighteen distinct varieties, Mr. J. Parker, Oakfield, Hitchin, was first with a good lot, Mr. E. Mawley being second. The Rev. H. Berners, Harkstead, Ipswich, was first for nine single trusses of any Rose except a Tea or Noisette with a good lot of Mme. Gabriel Luizet. For eight distinct varieties, three trusses of each, Mr. E. B. Lindsell was first with fine flowers, Mr. W. C. Romaine being second. The Rev. J. H. Pemberton showed a good lot in the class for twelve bunches, any varieties, not more than seven trusses to a bunch. The best were Horace Vernet, Mrs. John Laing, Caroline Kuster, A. K. Williams, Marie van Houtte, and Bouquet d'Or. Mr. H. V. Machin was second. Among growers of less than 1000 plants, Mr. Whittle, Belgrave Avenue, Leicester, was first for nine distinct varieties, single trusses; Mr. H. Foster, Ashford, Kent, being second. For six varieties, Mr. P. G. Burnand, Reigate, was first, and Mr. Whittle second. Mr. Bateman, Archway Road, Highgate, was first among growers of 500 plants for nine distinct kinds, the Rev. H. B. Biron, Hythe, being second. For six varieties, Mr. E. R. Smith, Muswell Hill, was first, and Mr. R. J. Jeans, Isle of Wight, second. Mr. A. Evans, Marston, Oxford, had the best four varieties in trebles, Mr. W. D. Freshfield, Reigate, being second. The Harkness Cup and first prize for twelve single trusses, distinct, was again won by Mr. O. G. Orpen, West Bergholt, with a fine lot, in which The Bride, Kaiserin Augusta Victoria and Comtesse Panisse were exceptionally fine; Mr. P. G.

Burnand was second. For six trusses of any Rose except a Tea, Mr. James Parker, Old Headington, Oxford, was first with Her Majesty; Mr. S. Price, Derby, was second. In the class for six varieties, open to amateurs who have never won a prize at a N.R.S. show, Mr. C. E. Shea, Foot's Cray, Kent, was first, and Mr. F. W. Champion, Reigate, second. Mr. Bowyer, Haileybury College, Hertford, was first for the same number in the class for new members of the society who have joined since last year's show, and Mr. S. Price, Derby, second. Mr. K. H. Gifford, Holyrood, Streatham, was first for six varieties grown within eight miles of Charing Cross, Mr. Smith, Muswell Hill, being second. For twelve distinct Roses grown within eleven miles of Charing Cross, Mr. M. Hodgson was first, and Mr. A. Beyfus, Norwood, second. The Rev. J. H. Pemberton was first in the class open to all amateurs for six new Roses, single trusses, showing Duke of Fife, Marchioness of Londonderry, Marchioness of Downshire, La Fraicheur, Mrs. Harkness and Mrs. Sharman Crawford; Mr. E. Mawley was second. Teas and Noisettes were also well shown by amateurs, Mr. Orpen winning the trophy and first prize for eighteen with an excellent lot, especially good being Francisca Kruger, Devoniansis, The Bride, Ernest Metz, Mme. Hoste, and Innocente Pirola. The Rev. A. Foster-Melliar was a good second, his stand containing the amateur's medal Tea previously mentioned. Mr. Orpen was also first for twelve Teas distinct, Mr. Ecthune, Denne Park, Horsham, being second. Mr. Orpen also showed the best nine single trusses in this section, staging Francisca Kruger in lovely colour, and was first likewise for eight distinct kinds, three trusses of each, the Rev. A. Foster-Melliar being second. Among growers of less than 500 Teas, Mr. Conway Jones, Hucclecote, Gloucester, was first for twelve varieties and for four trebles, distinct kinds, whilst for nine varieties, Mr. R. H. Langton, Raymead, Hendon, won first honours. Mr. J. Parker was first for nine varieties among growers of 200 Teas, and for six varieties, the Rev. F. B. Burnside and Mr. G. W. Cook, Torrington Park, Finchley, were equal firsts. Mr. J. Parker had the best nine bunches, seven trusses to a bunch, and Mr. R. W. Bowyer, Haileybury, was first for six distinct varieties in the class for those who have never before won a prize at the society's shows.

#### OPEN CLASSES.

These were well filled, especially those for one variety. These classes are invariably one of the finest features of the show, and contain some of the best flowers. Mr. Frank Cant showed the best lot of Hybrid Teas, a fine exhibit, the varieties La Fraicheur, Danmark, Lady Mary Fitzwilliam, Grace Darling, Germaine Caillet, Viscountess Folkestone, Duchess of Albany, Caroline Testout, Augustine Guinoisseau, La France and Kaiserin Augusta Victoria. Mr. B. R. Cant was second. Mr. G. Prince had the best twelve trusses of a yellow Rose, except Maréchal Niel, showing one of his matchless stands of Comtesse de Nadaillac. Mr. Mattock was second with the same variety. Mr. G. Mount had the best twelve blooms of a white Rose in Merveille de Lyon, Mr. Prince being a good second with Kaiserin Augusta Victoria. For twelve trusses of a crimson Rose, Messrs. Townsend were first with A. K. Williams, and Mr. B. R. Cant second with Gustave Piganeau. Mr. B. R. Cant and Mr. G. Mount were equal first for twelve blooms of a dark crimson Rose, both staging Fisher Holmes. In the class for twelve flowers of any light Rose there were eleven exhibits, Messrs. A. Dickson and Sons, Newtownards, securing first place with their new Rose Mrs. Sharman Crawford, which is of a charming pink colour, but too thin and shallow to become a great Rose. Messrs. Croll, of Dundee, were second with a good lot of Mrs. John Laing. For twelve trusses of any Rose not a Tea, Messrs. F. Cant and G. Paul were first and second with Her Majesty. Mr. B. R. Cant had the best twelve trusses of any Tea or Noisette, showing Mme. Cusin in rich colour. Mr. F. Cant was second with a lovely lot of Mme. de Watte-

ville. Messrs. Prier and Sons were first and Messrs. Townsend second for twelve blooms of *Maréchal Niel*, and Messrs. Dickson first for twelve flowers of any new Rose with Mrs. Sherman Crawford. The same growers were first for twelve distinct new Roses, single trusses, showing Helen Keller, Marchioness of Londonderry, Captain Hayward, Mrs. Sherman Crawford, Mavourneen, La Fraicheur, Marchioness of Downshire, Shamrock, Muriel Grahame, Lady Moyra Beauclerc, and Aveca. Mr. B. R. Cant was second.

None of the new Roses shown were considered of sufficient merit to receive a gold medal, but a cultural commendation was granted to two varieties shown by Messrs. Dickson, of Newtownards, one of which—a Tea named Muriel Grahame—impressed us favourably. The plant shown resembled *Mme. Hoste* in habit of growth, whilst the flowers were full, high in the centre, pretty in shape, and of a cream colour. The other variety was a H.P. named *Countess of Caledon*, apparently a strong grower, the flowers deep rose-pink. Mr. W. Taylor, of Hampton, also showed flowers of a sweet-scented crimson H.P. Messrs. Cooling showed a globular H.P. named *Bladud*, white, with blush centre, but probably a doubtful one to open.

#### GARDEN ROSES.

These made a charming feature, but the beauty of the display as a whole was lost through the scattering of the classes devoted to them. If they were placed as classed, visitors would see and enjoy them better, and they would make a bold break in the usual monotony of sloping boxes. There might with advantage be more classes for these even if those for the conventional kinds had to be reduced. For thirty-six bunches in distinct varieties, not less than three trusses to a bunch, Messrs. G. Cooling and Sons, of Bath, were first. Some of the best were *l'Idéal* in rich colour; *Marquise de Salisbury*, brilliant crimson; *Mme. Chedane Guinoisseau*, a lovely cluster flowered Tea; *W. A. Richardson*, *Gustave Regis*, *Mme. Falcot*, and *Bardou Job*. Messrs. Paul and Son were second. The best eighteen bunches were from Messrs. Townsend and Sons, *Mme. Charles*, *Celine Forestier*, and *Mme. Chedane Guinoisseau* being noteworthy. Messrs. Croll and Sons were second. Among amateurs Mr. Machin had the best eighteen varieties, showing *Polyantha*, *Noisettes*, and *Cluster* kinds, this exhibit receiving the silver cup given by Lord Penzance. In the smaller class Mr. O. G. Orpen was first, and Mr. Tate, Downside, Leatherhead, second. For twelve bunches of varieties suitable for button-holes, Mr. Mattock was first with a pretty lot, and Messrs. Townsend second; whilst prizes in the same order as named went to these two exhibitors for the best display of garden Roses arranged in a given space.

#### MISCELLANEOUS.

The chief group was that from Messrs. W. Paul and Son, Waltham Cross, who showed the best garden Roses of all sections in quantity, and arranged so that one could form a true idea of their merits and decorative value. Shallow baskets were filled with clusters of such kinds as *Marie van Heutte*, *Mme. Hoste*, *Edith Gifford*, *Camoens*, *Mme. Lambert*, *l'Idéal* and *Marquise de Salisbury*, and these had a telling effect. Some of their new varieties, such as *Sylphe*, *Clio*, *Corinna*, and *Duke of York*, were also well shown. These, with many older and well-known kinds, made a striking display tastefully arranged and remarkably fresh even at the end of the hot day. Mr. W. Rumsey, of Waltham Cross, showed Roses in variety, and Messrs. Jackman and Sons had a good exhibit of Hybrid Perpetuals and garden varieties, but there was nothing new in these groups, so we need not enlarge upon them. Mr. C. Turner, of Slough, showed *Crimson Rambler* Rose in quantity. Messrs. J. Laing and Sons also showed Roses, but the feature of the show apart from the Roses, and one which attracted much

notice, was their grand group of *Begonias*, arranged in a charming way with a light foil of *Asparagus plumes* and *Fern* to relieve the flowers. Some of their finest and newest varieties were prominent in the group. They also had a large group of *Caladiums*. Mr. Anthony Waterer showed his new *Spiraea profuse* in bloom and rich in colour. The group of *Calochorti* and *Lilies* from Messrs. R. Wallace and Co., Colchester, found many admirers. Messrs. J. Cheal and Son, Crawley, had a group of hardy flowers, and Mr. W. E. Tidy, Brockhampton Nurseries, Havant, showed a very large group of *Sweet Peas*, which comprised all the best varieties in rich and delicate colours, the flowers remarkably fresh and sweet.

A full prize list will be found in our advertisement column.

#### ROYAL HORTICULTURAL SOCIETY.

JULY 9.

ANOTHER good exhibition of varied produce was to be seen on Tuesday last; not so extensive, it is true, as the recent displays, but sufficiently so to make up a thoroughly representative exhibition. Roses were one of the features, and these were very fresh and bright in colour. Orchids were not so numerous, but several novelties and rarities, as well as good standard kinds, were to be seen. Outdoor fruits were thoroughly good, notably *Cherries* and *bush fruits*. Of indoor fruits the most numerous were *Melons*, but the rich luscious flavour so desirable in this fruit was confined to quite a few kinds. Vegetables were shown in very fine condition, being all the more noteworthy by reason of the prolonged drought.

#### Orchid Committee.

No first-class certificates were awarded at this meeting, but awards of merit were made to the following, viz. :—

*LÆLIO-CATTLEYA D. S. BROWN* (*Cattleya Trianae* × *Lælia elegans*), in which the growth and general contour of the plant were quite intermediate between those of the two parents, the flowers being of large size, the sepals and petals of a deep rose colour flushed with purple, the lip of a velvety dark purple shade with golden veins in the throat; an excellent hybrid. From Messrs. Sander and Co.'s collection.

*ODONTOGLOSSUM VEXILLARIUM CONSTANCE WIGAN*.—A lovely form of this species, the flowers of unusual size, having the lip of extra breadth, fully 4 inches, the colour being pure white, the sepals and petals retaining a slight rosy flush. From Sir F. Wigan's collection.

*VANDA TRICOLOR VAR. PLANILÆRIS*.—The flowers of this were particularly handsome both in form and marking, the sepals and petals being wider, thus giving a more massive appearance, the colour being a citron-yellow with rich brown spots, the lip rose-coloured with dark chocolate lines. From Mr. R. J. Measures' collection.

*BRASSIA VERRUOSA*, which, although quite an old Orchid, does not appear to have been certificated before. The plant in question bore fifteen good spikes of its pale greenish yellow flowers, making a good display, the individual blossoms being large and very fresh. From the collection of Mr. De B. Crawshaw at Rosefield, Sevenoaks.

Botanical certificates on this occasion were dispensed with a liberal hand, no less than thirteen awards being made as follows: *Dendrobium bracteatum*, a very singular species, flowering upon the old bulbs, not in any sense showy; *Lycaste Dyariana*, with pale greenish yellow flowers (from Peru); *Dendrobium speciosissimum*, which bears some resemblance to the old *D. infundibulum*, with less colour, but of similar character, being more erect in growth. These all came from Messrs. Sander and Co. *Eria Clauki*, a dull yellow species, with dense spikes of bloom from Messrs. Lewis and Co. *Masdevallia coriacea*, another of the singular and very interesting species, from Mr. R. J. Measures. *Polycinis muscifer*, a very elegant species, with small golden yellow spikes having bronzy spots; *Promenaea stapelioides*, of very dwarf growth, the sepals and

petals marked as in a *Stapelia*, the lip being intensely dark, almost black; *Oncidium cucullatum Lawrenceanum*, a small species, with dark purplish brown sepals and petals and a pale rosy purple lip; all from Lord Rothschild's collection at Tring Park. *Oncidium cucullatum Lawrenceanum*; *Luddemannia Pescatorei*, with small deep golden yellow flowers borne on pendulous and dense spikes; *Masdevallia guttulata*, bearing two quite small flowers to the one spike, these being light in colour, the growth also small and grass-like; *Trichocentrum bymenantha*, another miniature plant with small whitish flowers, these all coming from Sir Trevor Lawrence's collection. *Sarcanthus teretifolius*, with long Rush-like leaves, like *V. teres*, but longer, and long spikes of small dark-coloured flowers, from Mr. A. W. Witt, Maida Vale, W.

Messrs. Sander and Co. had the most important group in the hall, comprising many excellent things, amongst which were *Cattleya Gaskelliana var. Madouxiana*, in which the lip partook of *C. gigas*, with deep golden yellow in the throat, margined with purplish crimson; *Lælia amanda*, with soft, pale rosy lilac-tinted sepals and petals, the lip of a deeper shade, a beautiful variety; *Angulea uniflora*, with waxy white flowers, quite distinct and as large as *A. Clowesi*, which was also shown beside it; *Odontoglossum luteo-purpureum*, a good example; *Cattleya Wallisi*, with pale creamy white sepals and petals, the lip being dark maroon, with an orange-coloured blotch; *Lælia Cattleya Arnoldiana*, one of the most beautiful of the hybrids, with deep rose-coloured sepals and petals, the lip dark rosy purple and well expanded; *Lælia elegans Schrederiana*, with the sepals and petals of a soft flush of palest rose, the lip being of an intensely deep crimson-purple, very distinct in this latter respect, and an extra fine variety. *Dendrobium speciosissimum*, after *D. Jamesianum*; *Catasetum Christyanum*, with dark, almost black sepals and petals, an extra fine variety and in the best of condition; *Cattleya Rex*, with rich ivory white sepals and petals, the lip being shaded with a deep gold tint and rosy lilac and crimson markings, a fine species and very distinct; *Cattleya Gaskelliana virginalis*, a very distinct pale form with slight traces here and there in the lip of pale purple; *Dendrobium Phalaenopsis Schrederianum*, good examples with fine spikes from the old bulbs; *Cattleya Brymeriana*, a supposed natural hybrid (*C. Eldorado* × *C. superba*), showing *C. superba* quite distinctly, but quite distinct therefrom, the lip having purplish crimson markings with golden yellow in the throat, were also sent. *Odontoglossum Harryanum*, very fine and rich in colour; *Odontoglossum vexillarium*, in very fine forms, one called *Empress Augusta Victoria* being of a deep rose colour and of large size, another named *Chelseiense*, a much paler form, but with deep crimson lines and ground at the base of the lip; another called *conspicuum* being also distinct; *Cypripedium nobilium*, an excellent hybrid; *Cattleya Miss Measures* (*C. speciosissima* × *C. velutina*), a pleasing hybrid showing the former parent in the lip, the sepals and petals being shaded in a peculiar way with rose and bronze, were also included. Award silver Banksian medal.

Mr. George Marshall, Grimsby, had a smaller, but excellent group, consisting chiefly of *Cattleyas*, in which good forms of *C. gigas* were conspicuous, *C. Mendeli* being also included as well as *C. Gaskelliana*. The most noteworthy plant, however, was a grand example of *Epidendrum vitellinum majus* with several very stout spikes and large blooms. Award silver Banksian medal.

Messrs. H. Low and Co. had an attractive and showy group, amongst which were two distinct forms of *Oncidium Lanceanum*, this charming species being still all too scarce. *Odontoglossum Roezli* and *O. Roezli album* were again included here. *Oncidium macranthum* was specially good, being rich in colouring. *Odontoglossum crispum*; *Cattleya superba*, a good piece; *Oncidium Marshallianum*, with several stout spikes freely branched; *Grammatophyllum Measuresianum*, with one long spike; *Lælia grandis tenebrosa* and

*Cattleya granulosa*, both good, the latter specially so; *Cypripedium Curtisi*, *C. Alice* (hyb.) showing *C. Spicerianum*, also *C. Veitchi*, and a good plant of *Aerides Lobbi* were also sent (award bronze Banksian). Messrs. J. Veitch and Sons showed another of their hybrid *Dendrobies* in *D. porphyrogastrum* (*D. Dalhousianum* × *D. Huttoni*), with large flowers of the palest tint of porphyry, a most delicate shade, and a beautiful hyb. *Cypripedium Dominicanum albicans*, a pale form of this older hyb., very distinct and pleasing, with long tail-like petals. Mr. R. J. Measures had several cut Orchids, amongst which was *Laelio-Cattleya Schilleriana*, flowers large, the sepals and petals being flushed with the softest tints, the lip quite in contrast, being of a dark velvety purple. *Vanda Parishii*, with its rich aromatic perfume pervading the atmosphere, was also to be seen here in good character. *Pleurothallis longissima*, with long slender spikes of the palest of green flowers, a fitting companion to *Dendrochilum filiforme*; *Odontoglossum Harryanum*, well developed spikes; *Cattleya Gaskelliana* and *C. Gaskelliana albescens*, the latter very distinct and beautiful; *C. Wallisi*, a fine form of this beautiful *Cattleya*; also *C. Mendeli*, in which the colour of the sepals had run into the lip in a singular fashion, were also sent. From Messrs. Lewis and Co. came *Laelia grandis tenebrosa*, *Cattleya Gaskelliana* and *C. Harrisoni*, all in good condition; also *Polystachys lutcola* and *Bifrenaria vitellina*, with deep golden yellow flowers; *Cynorchis grandiflora*, a singular Orchid with greenish sepals and petals and a rosy lilac lip; *Oncidium Schlimi*, a good spike; *Cypripedium niveum superbum*, a larger form; *C. leucorrhodum*, *Dendrobium thysiflorum*, *Laelia grandis tenebrosa* var. *Bella*, with pale-coloured flowers; also *Cattleya citrina* and *Vanda Lewisii*, a miniature species.

From Sir Trevor Lawrence came *Vanda Roblingiana*, with brownish spots on a green ground, the lip fringed, and of singular formation; *Masdevallia Rolfeana*, of dwarf growth and with dark coloured flowers; *M. Peristeria*, pale greenish yellow with darker spots; *Polystachys Lawrenceana*, tawny yellow sepals and petals, and pale bluish lip; *Masdevallia Stella* (hyb.), soft rosy pink, a lovely shade of colour; *Odontoglossum vexillarium superbum*, with small flowers, deep rose colour with dark crimson blotch on lip, edged with white; *Dendrobium revolutum*, with pure white sepals and petals, the lip being unusually large, and of a pale greenish yellow; *Pleurothallis macrolepharis*, extremely beautiful and interesting, the small dark flowers being borne on hair-like stems; and *Nanodes Medusæ*, an Orchid that is rarely shown, being both singular and interesting.

From Mr. Malcolm Cook, Kingston Hill, came a fine cut spike of *Cattleya gigas* with four flowers, and Mr. F. A. Brown, Lawn Bank, Teddington, sent *Schomburgkia tibicinis*, brighter in colour than usual, evidently a good form. Mr. J. Gurney Fowler sent *Laelia grandis tenebrosa*, a pale variety with light bronzy sepals and petals, the lip still retaining the deep purple colour.

Mr. J. Foster Alcock, Northchurch, Herts, exhibited a specially fine *Odontoglossum Harryanum* rich in colour; this splendid *Odontoglossum* has rarely been seen in a finer variety. From the same source came *Odontoglossum crispum*, well flowered and good spikes; also *Laelia grandis tenebrosa*, a small plant of a distinct form.

#### Floral Committee.

First-class certificates were granted to the following:—

**HEMEROCALLIS AURANTIACA.**—A new variety of robust character and striking beauty, with large flowers of a rich apricot colour. A note describing it more fully, appears on another page. It was shown by Messrs. R. Wallace and Co., of Colchester.

**ARNEBIA CORNUTA.**—This handsome Borage-wort is an annual of brilliant and showy colour, the flowers rich yellow, with five large spots of velvet-brown on the corolla. The flowers are borne

profusely in a long succession. From Messrs Dobbie and Co., Rothesay.

Awards of merit were given to the following:—

**BEGONIA CARMINATA.**—This is a hybrid, the result of crossing *B. Dregei* with *B. coccinea*, and handsomer than either of its parents. It has the long, deep green leaves of *B. coccinea*, but instead of being smooth-edged they are lobed, as in *B. Dregei*. The flowers are rosy-carmine, numerous, in drooping, branched racemes, and the plants free-flowering even in a young state. Shown by Messrs. J. Veitch and Sons.

**BEGONIA MR. F. BOSTOCK.**—A double-flowered variety, free and robust, the flowers double, but graceful in outline and of a bright scarlet colour. From Messrs. J. Laing and Sons.

**CALOCHORTUS LUTEUS CONCOLOR.**—This is a new and sturdy variety having stout stems, which grow about 1 foot high. The flowers are large, of a rich buttercup yellow colour, with a few faint brown markings at their base. Shown by Messrs. R. Wallace and Co., Colchester.

**CALOCHORTUS MACROCARPUS.**—Though not new, this is not a common species. It has the largest flowers of any, and those shown were very fine, of a lilac purple colour, lighter at the base, which is clothed with long silky yellow hairs. This also came from Messrs. Wallace and Co.

**CARNATION MRS. W. BRIGHT.**—A fine flowered variety of a rich yellow colour. A stand of cut blooms and a strong plant in a pot were shown. Most of these yellow selfs disappoint when tried in the open ground. Shown by Miss McDonald, Northgate Nurseries, Chichester.

**GODETIA MARCHIONESS OF SALISBURY.**—This has a bright effect in the mass as shown, as there is much less purple in the colour than in that of most *Godetias*. The flowers are rosy crimson margined with white, flushed with pink, the habit vigorous and free. From Messrs. Daniels and Sons, Norwich.

**ROSE HAILEYBURY.**—This is a Hybrid Perpetual variety, the flowers as shown only of medium size, but full and good in form and colour, which is light crimson. They are also sweetly scented. Shown by Messrs. G. Paul and Son, Cheshunt.

**STREPTOCARPUS LAING'S MULTIFLORA.**—A pretty form with a rather stupid name. It is an abundant flowering kind, the blooms large, rich blue, feathered with deep violet-purple in the throat. From Messrs. J. Laing and Sons, Forest Hill.

There was a considerable falling off in the number of miscellaneous groups, but that from Messrs. R. Wallace and Co., of Colchester, was a centre of attraction throughout the day and deservedly merited the silver Flora medal awarded. The new Day Lily in the centre of the group was conspicuous. Lilies, too, were plentiful, including *L. auratum*, *L. longiflorum præcox*, an early form, and *L. canadense*, in red and yellow varieties. The lovely *L. Krameri* was shown, also *L. Parryi*, which has rich yellow, sweet-scented flowers and is a most beautiful kind to grow in moist, peaty places. Two charming small Lilies were *L. Coridion*, with yellow flowers, spotted with brown, and *L. concolor*, a dwarf species, which holds its flowers erect. They are of a brilliant scarlet colour with dark spots. Among *L. elegans* varieties the extremes of colour were seen in the varieties *Horsmani*, with its dark, blackish crimson flowers, and *Alice Wilson*, which is rich lemon-yellow, with a darker band of colour down the centre. *Calochorti* were again largely shown. *Brodiaeas* in variety were also shown, and some good forms of the Japanese Iris. Messrs. Barr received a silver Banksian medal for a good group of the best hardy flowers in season, the chief features being *Sea Hollies* in variety, *Lathyrus latifolius* in several forms, *Anthemis tinctoria* Canary Bird, a rich yellow variety of this fine hardy Daisy, *Lilium Browni*, *L. longiflorum*, and *L. testaceum*. *Platycodons* were good, also Japanese Irises, *Achillea filipendula*, *Pink Ernest* *Ladhams*, *Statice*, and *Sweet Peas*.

Mr. H. Eckford showed a great many varieties of Sweet Peas, a bunch of each kind in a separate

vase. There is certainly no finer annual flower, as it embraces such a wide range of colour. Among those shown we noted Mrs. Sankey and Blanche Burpee, white; Peach Blossom, a lovely shade of pink; Novelty, rich rose; Duke of Clarence, deep maroon; Stanley, of a similar hue; Countess of Aberdeen, blush-pink; Captain of the Blues; Queen Victoria, cream; and Lady Hamilton, of a lovely lavender shade. A silver Banksian medal was awarded, and a similar award was made to Mr. Charles Turner, Slough, for Carnations, cut flowers staged with the conventional collar round their necks, and every flower dressed so that no individuality of form was apparent in any of them. Messrs. Sander, of St. Albans, showed a pink perpetual-flowering Carnation, and Mr. J. Douglas, of Great Bookham, exhibited several very fine varieties, as *Corinna*, yellow; Hayes Scarlet, a brilliant colour; Grace Darling, spotted purple; and Lady Ridley, white self. Mr. H. Becker, Jersey, showed a pink self Carnation somewhat resembling Countess of Paris, but distinct, and called Jersey Maid, and Messrs. Cutbush showed a rose and salmon variety named *La Vilette*. Mr. Anthony Waterer again showed his *Spiræa* in good condition, and another new form of the same free flowering character named *S. Margaritæ*, with rosy pink flowers. It is quite distinct, and will make a charming companion to the crimson variety. Messrs. Sander and Co. showed *Dipladenia atropurpurea* in small plants freely flowered, also *D. boliviensis*, which is white, with a yellow throat. Half-a-dozen vars. of *Sonerila* varied and pretty in their leaf markings, *Eriocnema Sanderae* in good leaf colour, and a fine pan of *Dionæa muscipula* came from the same firm. Messrs. J. Veitch and Sons showed six very fine spikes of the rich yellow *Eremurus Bungei*, which were much admired. Messrs. Sutton and Sons, Reading, sent a good lot of *Nemesia strumosa* in wide range of colour, from pale yellow to rich crimson with numerous intermediate and indescribable shades. *Paneratium collinum* was shown by Messrs. Lewis, of Southgate, and an ugly double purple and white *Petunia* came from Mr. Beldam, The Lodge, Acton. A very fine seedling form of *Chrysanthemum maximum* was shown by Mr. Middlehurst, of Liverpool, and Messrs. Laing and Sons showed several good new *Begonias*. Mr. J. Forbes, of Hawick, sent a fine lot of *Delphiniums* which, however, did not bear their long journey very well, and a *Godetia* named *E. F. Fairbairn* was shown by Messrs. Fairbairn, of Carlisle. Messrs. Daniels, Norwich, showed a quantity of an Ivy-leaved *Pelargonium* named *Queen of Roses*, the trusses compact, the flowers large, very double and of a deep rose colour. A vote of thanks was given to Mr. G. F. Wilson for a fine flower of *Cereus Alice Wilson*, a lovely variety raised in America by Mr. C. M. Hovey. Mr. G. Paul showed several new *Roses*, one named *Bacchus* looking very promising as a garden variety. It is a Hybrid Perpetual, bearing rich velvety crimson flowers of medium size on long stems.

#### ROSES.

Special prizes were offered for *Roses* and some very fair flowers were shown, but the competition was not so strong as in an average season. Mr. Frank Cant was quite to the fore in the open classes, securing first prize for twenty-four distinct single trusses of Hybrid Perpetuals, and the same in another class for that number of Teas. For twelve of one variety of Tea Rose he was also first, Mr. B. R. Cant being second in all three classes.

For twelve distinct varieties of H.P.'s, three blooms of each, Mr. B. R. Cant was first, and Mr. G. Mount, Canterbury, second, and the same order obtained in the class for twelve single trusses of any variety of H.P., Mr. B. R. Cant showing a grand dozen of *Gustave Piganeau*, while Mr. Mount staged *A. K. Williams*. In the amateur classes for twenty-four distinct H.P.'s, single trusses, Mr. E. B. Lindell, Hitchin, was an easy first with a grand stand of fine flowers, Mr. T. B. Haywood being second. For twelve

distinct single trusses, Mr. J. Gurney Fowler, South Woodford, was first, and Mr. O. G. Orpen, West Bergholt, second. In the corresponding open class Mr. B. R. Cant was first, and Mr. Mount second. For six single trusses, amateurs, Mr. Langton, Hendon, was first, and Mr. K. H. Gifford, Streatham, second, whilst for six blooms of one variety, Mr. Haywood and the Rev. J. H. Pemberton were first and second respectively with A. K. Williams. Mr. Orpen had the best twenty-four Teas among amateurs, showing some fine flowers, and Mr. H. V. Machin was second. Mr. Langton showed the best six Teas, single trusses, Mr. C. J. Grahame, Croydon, being second, and for six of one variety Mr. Langton was first with Innocente Pirola, and Mr. Orpen second with Souvenir d'un Ami. We have not enumerated the best blooms in the larger stands, as they practically correspond with the selections made and to be found in our report of the Palace show.

#### Fruit Committee.

The exhibits at this meeting were numerous, very fine fruit and vegetables being staged, the Cherries from Gunnersbury House and the fruit in quantity from Messrs. Veitch, Chelsea, being most admired. Melons were again sent in great numbers, but only two found worthy of an award.

Awards of merit were given to—

**MELON EPICURE**, a round fruit, above medium size, flesh deep green, finely flavoured, with bright skin, the latter much netted. From Mr. Mortimer, Swiss Nursery, Farnham, Surrey.

**MELON NUGGET**, flesh bright scarlet, the fruit round, well netted and richly flavoured. This is so far the best Melon of the year. Also from Mr. Mortimer.

Messrs. Veitch, Royal Exotic Nurseries, staged a very fine collection of Cherries, Gooseberries, Currants and Raspberries. The Cherries had been grown on pyramids at their Langley nursery, and comprised the best varieties, no less than thirty distinct kinds being staged. Bigarreau Napoleon and De Schreken were very fine. Among the black kinds the Tartarian was specially good, also Elton, Royal Duke, Empress Eugénie and Governor Wood. Mammoth, a large yellow mottled fruit, was very good; also Reine Hortense (one of the Duke section), Archduke, Royal Duke and May Duke. Very fine fruits of Raspberry Superlative and Yellow Antwerp were staged, both growing branches and gathered fruits. The Gooseberries were also staged in a growing state from cordons, and comprised the leading varieties, the best being Forester, Early Red Hairy, Bright Venus, Early Sulphur, Golden Drop, Hedgebury, Green Gascoigne and Overall. Among the Currants the White Grape was very good (silver-gilt Knightian medal). Mr. J. Hudson, Gunnersbury House, Acton, staged three large boxes of Cherries, the varieties being Bigarreau Napoleon and Black Tartarian. The fruits were equal to the best fruits grown under glass. Growing branches were also staged to show cropping qualities, the shoots being heavily laden with fruit (silver Banksian medal).

Mr. E. Beckett, Aldenham House (Gardens, Herts), staged twenty-four dishes of vegetables in some eighteen varieties, every dish being specially good, well meriting the award given. Tomatoes Perfection, Chemin, and Polegate were very good, as also Walcheren Cauliflower, Snowball Turnip, Prodigy and Duke of Albany Peas, Canadian Wonder Beans, and three varieties of Potatoes (silver-gilt Knightian medal). Mr. W. Empson, Amptill House, Beds, staged a large collection of vegetables with nine dishes of fruit, but we do not think it adds to the value or appearance of the vegetables to stage fruit with them. Foster's Seedling and Black Hamburgh Grapes were good, as also Brown Turkey Figs, Waterloo Strawberries, and Superlative Raspberry. Early York Cabbage, Stratagem Peas, Snowball Turnip, and other vegetables were also well shown (silver Banksian medal). Messrs. Veitch, Chelsea, staged no less than thirty-six varieties of Peas. This was an instructive exhibit, and though the season has been

most unfavourable for this crop very good examples were staged. The most noticeable dishes were Stratagem, Invincible, Pride of the Market, Mainerop, Daisy, Masterpiece, Alderman, and Veitch's Perfection (silver Banksian medal).

Mr. Eckford, Wem, Salop, sent seven new seedling Peas of great merit, but as the cropping qualities could not be tested they were referred to Chiswick for trial. Mr. Ward, Longford Castle Gardens, Salisbury, sent a new Pea of nice appearance. This, too, was requested to be sent for trial. A new field Pea named Parish Councillor, large and good, was sent by Mr. A. Gray, Hertingfordbury Park, Herts. Messrs. P. Barr and Son, Covent Garden, had a collection of Peas and Lettuces, also nice examples of St. John's Day Cabbage. Mr. Gilbert sent a new Cauliflower named Burghley Pet, of compact habit and with pure white curd. A new seedling Cucumber came from Mr. Kneller, Malshanger Park, Basingstoke, a nice looking fruit. Mr. S. Groves sent nice looking fruits of Tomato Temple Favourite, with large smooth deep flesh of a dark colour.

From the Society's gardens came a very interesting collection of Red and White Currants, also fruiting branches of the same. The most notable were Fertile de Palluan or Red Cherry, Houghton Castle, one of the best Red Currants grown; the old Dutch Mallow-leaved or Raby Castle, a strong grower, fruit large, very acid; the cut-leaved De Verrier and Wilmot's Red, the same as the Red Dutch. The best white kinds were Large White, Cut-leaved, Macrocarpa and White Dutch. Mr. H. Becker, Jersey, received a cultural commendation for two varieties of Currants. Nice Pineapples and Humboldt Nectarines came from Mr. Kemp, Stoke Park, Slough. Some very long fruiting branches of Raspberry Papworth Prolific came from Mr. Papworth, Caterham, but the fruits were small. A new Raspberry, much like a Blackberry, was sent by Mr. Farini, Dartmouth Lodge, Forest Hill. Seedling Strawberries, crosses between several new kinds, came from Mr. Carmichael, Pitt Street, Edinburgh. Those sent were not in condition to test quality. Peaches Royal George and Noblesse were sent from the Horticultural College, Swanley, also Melons (Golden Queen, The Empress and Her Majesty. Mr. Smythe, Basing Park, Mr. Ashton, Glossop Hall, Derby, Mr. Richardson, Cheadle, Mr. Pettigrew, Cardiff Castle, Mr. Wythes, Syon House, Mr. Bishop, Wightwick Manor, and others sent seedling Melons, but none were deemed worthy of an award.

The lecture was by Mr. Francis Darwin, and dealt with "The effect of darkness upon the growth of plants." He was favoured with a good audience and much interest was manifested.

**Gardeners' Royal Benevolent Institution.**—We learn that the Worshipful Company of Skinners have given a donation of £10 10s. in aid of the funds of the Gardeners' Royal Benevolent Institution.

**The weather in West Herts.**—For the fourth time this year the highest temperature in shade has touched 80°, or exceeded it. The warmest days during the past week were the 7th and 8th, when the maximum readings were respectively 78° and 80°. The days lately have been hot, but the nights, on the other hand, cold for the time of year, which is usually the case in the type of weather recently prevailing. At 1 foot deep the temperature of the ground is at the present time 6° above the July average, and 5° warmer than at the same date last year. No rain, beyond that deposited by a passing shower, has fallen during the past nine days. The present drought may be said to have set in here on April 28, since which time (ten and a half weeks) the total measurement only amounts to little more than 1 inch, while no rain water at all has come through either percolation gauge for over six weeks. On the 8th inst. the air was again very dry indeed, the difference

between the readings of a dry bulb thermometer and one with its bulb kept constantly wet amounting to 20° at 3 o'clock in the afternoon.—E. M., *Berkhamsted*.

## PUBLIC GARDENS.

**Open spaces.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding, it was reported that St. Stephen's ground, North Bow, and some small grounds in Canning Town were being laid out; that the Friends' burial ground in Long Lane, S.E., would shortly be commenced; that the purchase of 10 acres in Hermit Road, E., for a recreation ground, towards which the association had subscribed, was almost completed; and that additional seats had been accepted for Hackney Churchyard. It was agreed to give the support of the association for the acquisition of Churchyard Bottom Wood, Highgate, and of a recreation ground for Barking Side, Ilford, E. Plans were considered for the laying out of St. James's Churchyard, Pentonville Road, and Christ Church Churchyard, Blackfriars Road, S.E., and progress was reported with regard to the efforts the association was making to acquire sites for recreation grounds at Putney, Walworth, and Deptford, in each case involving the collection of considerable sums of money, towards which contributions were asked.

## OBITUARY.

**Death of Mr. John Wills.**—Just as we are going to press we regret to hear of the death, at the age of 64, of Mr. John Wills, of Onslow Crescent, South Kensington. He had been in ailing health for a long time.

**Insects on Roses.**—Will you kindly tell me if this is a destructive fly among Roses, as my employer thinks it is the same that is so destructive to Roses in the south of Italy?—P. ELDER.

\* \* The insect you sent is one of the sawflies which attack the Rose, or rather it is their grubs which do so. The flies themselves are very harmless, but they lay their eggs on the leaves, and the grubs which are hatched from them are very destructive to the foliage. Picking them off by hand is the best way of getting rid of them. They are not very easily detected among the foliage, but as soon as you have found one or two, you will not have much difficulty in seeing the others.—S.

## BOOKS RECEIVED.

"Manual of Forestry." Vol. iii. Forest Management. W. Schlich. Bradbury, Agnew and Co., Ltd., Bouverie Street, London, E.C.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHIDS.

## ORCHIDS FOR GROUPING.

ALTHOUGH there are no plants so admirably adapted for grouping so as to get light and beautiful effects as Orchids, possibly there are none so frequently spoilt by flat uninteresting arrangement—a bank of flowering Orchids interspersed with Ferns and other fine-foliaged plants, kept high at the back, sloping regularly down to the front, and edged with creeping plants. How frequently this is repeated at our large exhibitions. There is a gorgeous wealth of blossom and enough material often to cover double the amount of space, but artistic or pleasing effects are wanting. With regard to trade groups there is the excuse to be urged that the space allotted is limited, and nursery-men wish to show as much as possible in order to give the public a sight of as many as possible of their treasures and connoisseurs an opportunity of comparing varieties. But with private growers, either at exhibitions or at home, there is not this inducement to crowding, and yet it occurs none the less. Respecting the arrangement of Orchids at home, there are very many places where a suitable structure for the purpose does not exist. Flowering houses (as usually understood) are built much on the same principle as those for growing, the only difference being a smaller amount of piping and a little different arrangement of the stages. An ideal house for the purpose is one without any staging whatever, but plenty of floor space, whereon the floral arrangements can be varied at will. The walls would have to be clothed with greenery of some kind, some of the hardier *Adiantums* and other Ferns that will thrive and look green in a moderately dry atmosphere being most suitable. A few larger-growing and graceful-habited kinds, such as *Woodwardia radicans* or *Microlepia hirta cristata*, should be planted to prevent a flat or formal appearance. The temperature must, of course, be kept mild and genial, and pipes would, if left bare, be unsightly. These should either run underneath the floor level or, if kept inside the house, be covered in some way. Rockwork is the means that at once suggests itself, and this, if prettily conceived and carried out, is excellent, and quite in keeping with a natural and pleasing mode of arrangement. An informal surface will be the first consideration, and in the construction plenty of outlets for the heat must be provided, these being kept out of sight by judicious planting. Niches must also be left for placing Orchids in when in flower. A somewhat subdued light is always to be preferred, as Orchid flowers of all kinds are better viewed in such than in a very light house, the lovely blendings and combinations of colouring being greatly enhanced. I know of nothing more charming or natural looking than the scendant scapes of such as *Oncidium macranthum* about the stems and under the leaves of Tree Ferns or Palms, and if a few healthy specimens of the latter are obtainable, the task of the decorator is considerably lessened. But these must not be placed at the back with plants hiding the stems, or the graceful curves of the foliage cannot be seen.

Coming to the front of an imaginary group, in conspicuous places mounds of varying height

and outline may be formed, the material, of course, differing according to the season and individual circumstances. *Masdevallias* of the brightly coloured species may peep out from amongst the fronds of Maiden-hair or dwarf *Asparagus*, these giving place higher up to the arching spikes of *Odontoglossum crispum* or *O. Pescatorei* very thinly disposed, the whole surmounted by a nicely furnished *Coccoloba Weddelliana* or similarly habited Palm. This would have a charming appearance, while further back upon a base of some trailing or low-growing plant the more erect varieties, such as *Oncidium Marshallianum*, *crispum*, and others, or *Calanthe Veitchii* or *C. vestita* might be arranged with telling effect. Brightly-coloured fine-foliaged plants, as *Crotons* or *Coleuses*, are, I think, totally out of place when grouped with Orchids, these garish effects being distinctly inferior to the restful and impressive combination formed by the simple greens of the Ferns in conjunction with the subdued tints of Orchids. The ever-green *Dendrobes* have a wonderfully fine appearance when tastefully arranged with *Cattleyas* and *Lælias*, or with the more simple flowering *Miltonia vexillaria*. Thus dozens of pretty combinations may be mentioned, but these will suggest themselves as the work proceeds, and must necessarily vary according to circumstances. The principal points to be aimed at are an undulating surface and a light graceful effect, nothing being crowded, and yet while not exactly balanced, yet seemingly wanting nothing to complete it. No other flowering plants should be introduced if it can possibly be avoided, Orchids having an appearance entirely their own and possessing certain qualities wherein no others can vie with them. If a display has to be kept up and Orchid flowers are scarce, the best plants to use are those with simple, though brightly-coloured flowers, such, for instance, as *Poinsettias*, during the winter months, or *Anthuriums* while these are in flower. These heighten the effect of the Orchids and do not suffer by contrast. Such plants as *Lilium auratum* and other richly marked species must be avoided. H. R.

**Cattleya superba.**—"R." writing on *Cattleya superba*, says: "Personally I prefer pots or baskets for this species." I have in a previous number of THE GARDEN stated my experience with this fine *Cattleya*. I quite agree with "R." that small plants are not worth the trouble of growing. My first experience with it was about twenty-five years ago, when I was feeling my way in Orchid culture, and I knew nothing at all about the requirements of *C. superba*. I bought six fine large plants, and was recommended by the late Mr. Domy to grow them in pots like other *Cattleyas*. This I did, and can truly say they had my best personal attention, but I could plainly see that they were not happy, and one after another died off until two only were left. I therefore cut two lengths of Tree Fern, each about a foot in length, and turned the two plants out of the peat and Sphagnum and placed them on the Fern stumps. They improved henceforth and flowered admirably every year. Mr. Pilcher flowered this species beautifully when gardener to the late Mr. Rucker at Wandsworth. It requires plenty of heat and moisture when growing and to be kept clear of thrips, which is its worst enemy.—J. DOUGLAS.

**Vanda teres.**—This is now beautifully in flower with me and grows like Willows, making growths a foot to 18 inches in length in about twelve months. It will stand as much heat, light and moisture when growing as any Orchid known to me and continues to do so. I grow the plants on a long upright raft of teak rods. The base of the raft is plunged in clean crocks and surfaced to the depth of 2 inches to 3 inches with chopped Sphagnum Moss in a fresh state. The base of the

rod-like stems is inserted in the Moss and the plants soon attach themselves to the rods by their roots. It is quite an aerial rooting species, as in some instances the roots in the Moss are quite dead, whilst those twisted in and out amongst the teak rods are fresh and vigorous. Now is the season of growth, or at least as soon as the flowering period is over. Keep the plants in free rapid growth close up to the glass, shutting up the house early in the afternoon to raise the temperature to 90° or 100°. When the growth is completed gradually reduce the temperature and winter the plants in the *Cattleya* house, keeping them quite dry at the roots.—J. D.

## PERISTERIAS.

NOT many species of this genus are really popular plants, but one—*P. elata*—deserves a place in every collection. They are all characterised by the large egg-shaped pseudo-bulbs and handsome leaves, which on healthy plants of the above species are frequently 2 feet 6 inches or upwards in length. Being extremely free growing and of a terrestrial habit they require a strong substantial compost, one in which loam predominates. Three parts of this to one of peat fibre or good leaf-mould will make a capital basis, and to this must be added a good sprinkling of crocks and chopped Sphagnum. In potting, the base of the leading pseudo-bulbs must not be buried, but just rest on the compost, which must be kept below the rim of the pot. Good drainage is essential, and this must be carefully protected by a layer of rough Moss until the roots have taken a good hold of the compost. After potting, which should take place just before growth commences in spring, the plants must be placed in a brisk heat and carefully watered till the roots are well on the move. A thin layer of Sphagnum over the surface does away with frequent watering and hastens the formation of roots somewhat. When in full growth *Peristerias* will require ample supplies of water, varying this with occasional doses of weak liquid manure as the pseudo-bulbs approach completion. This treatment will cause a vigorous and healthy growth, without which it is useless to expect them to flower freely. After the pseudo-bulbs are well finished the water supply must be gradually diminished until in winter only enough to keep the compost just moist will be required. The chief insect enemy to be combated is brown scale, but with ordinary care and a timely application of the usual remedies this is not much to be feared. A black spot or rot sometimes attacks the base of the pseudo-bulbs, but this is usually caused by too much water combined with too little heat during the resting season. The plants should not be taken from the *Cattleya* house all through the year unless when in flower.

**P. CERINA** is a remarkably handsome species bearing about midsummer short pendulous flower-scapes, the blossoms being clear yellow in the type, the var. *guttata* being dotted with purple. These are strongly scented and last long in good condition. The growth of this plant is stronger from pots than baskets, but in the latter the blossoms of course show to greater advantage. *P. cerina* was introduced from Mexico in 1835.

**P. ELATA.**—The well-known Dove Orchid is a free-growing, stately habited plant introduced from Panama in 1826. The flower-spikes spring from the base of the pseudo-bulbs and rise to a height of 3 feet or more, producing the blossoms most freely and continuously for five or six weeks. Each blossom bears a strong resemblance to a dove as it appears when about to alight with wings partly erect. The sepals and petals are simple in form, concave and pure white. It flowers from the beginning of July until September.

*P. PENDULA* is a distinct and handsome species from Demerara. The pendulous flower-scapes bear upwards of a dozen flowers, which are powerfully fragrant, yellow, suffused with rose and dotted with purple. This may also be grown in baskets, and though a shy flowering kind should be more grown. A variety of this plant, *P. p. Rossiana*, first flowered by an Italian Orchid grower, to whom it is dedicated, is a rare plant, differing in colour from the type which has been in cultivation since 1855.

#### SEASONABLE NOTES ON ORCHIDS.

THE weather is still of a tropical character, and the amount of damping and watering required is extraordinary. Indeed, it seems that the present season is likely to rival 1893, at least in this neighbourhood (Suffolk). Cattleyas of all kinds are showing, by their healthy-looking growths, how much they enjoy the bright sunlight. What a splendid grower *C. labiata autumnalis* is. I had quite given up hopes of seeing flower-sheaths on some newly-imported plants that were badly infested by *Cattleya grub* in the spring. Now, however, they are showing at nearly every growth. One can hardly help contrasting this with *C. gigas*, of which several grand growths that have been made without any check whatever are quite flowerless, even in this season. It is high time to warn growers to be on the watch with this latter species, and by any means in their power to keep it dormant after the flowers are past or the growths completed. *C. Lawrenceana* positively revels in the brisk heat and is making a splendid growth. Some fine growths of *C. guttata Leopoldi* I saw recently had gone off in a peculiar manner. The sheath first started to damp about half-way up the forming bulb, and from this the decay spread to the underlying tissues, the bulbs being at last so weakened that they snapped off. Nothing was amiss with it either above or below, and the plants were otherwise thoroughly healthy. They had not been syringed overhead, nor was the atmosphere kept unduly moist. The good old *Oncidium incurvum* is making a brave show as usual, the growths also being nearly complete. The removal of the plants to a drier atmosphere conserves the blossom, and also consolidates the new bulbs. *Stanhopeas* require great care in order to keep down red spider, the plants delighting in copious supplies of water now both overhead and at the root. *S. eburnea* favours us with a few flowers occasionally, and one plant has been almost constantly in bloom for over two months, the flowers, though very fleeting, being freely produced. Many of the species do not usually flower much the first season after being disturbed at the root for re-basketing, but this kind seems exceptionally free. *Thunia Marshalliana* is flowering rather irregularly this season, those plants with five or six shoots to each pot coming one at a time, thus showing the advisability of keeping to a smaller number. The plants when in flower may easily be grouped, and thus a better display made than under the former treatment. These are usually placed in a sunny frame after flowering, where later on the *Dendrobiums* will keep them company. The favourite *D. Phalaenopsis* seems equally at home either in pans suspended near the roof, in baskets or in pots on the stages, the chief requirement apparently being a very high, moist temperature, with not too much rooting space. The useful *D. Dearei* is also quite happy under similar conditions, and the pretty white flowers, with the faint tinge of green on the lip, are just now very attractive.

In the cool house *Disa grandiflora* is pushing up its flower-spikes and will soon be in full beauty. This plant requires an enormous amount of water when growing freely if the specimens are healthy. As long as this is the case insects do not usually trouble it, but once they begin to go back, either green fly or thrips or both pounce down on the plant and put an end to all hopes of flowering. Although the water supply must be lessened after flowering, at no time must this Orchid be really dry at the root, for though no top growth is apparent, an important work is going on below in the swelling up of the immature crowns and the production of offsets. These offsets, by the way, are often freely produced through the side of the perforated pots, and are a recommendation to this kind being used. The great heat has rendered it very difficult to keep *Odontoglossums* and *Masdevallias* in pits or frames cool enough, ventilation only making matters worse by causing a dry atmosphere. The nights are cool and refreshing, however, and the lights being left entirely off, the plants get the full benefit of what little dew there is. A shower of rain during the day is a great help, and they must be exposed to get the fullest advantage. Mats should be laid on the glass of the cool house in addition to the blinds and kept moist by syringing several times during the day. Where much syringing overhead is practised those plants that are finishing their growth must be kept apart or there is a danger of their starting again into growth to the detriment of the flower-spikes, these never being so strong when the new growths are pushing at the same time. Great care is necessary with *Odontoglossums* in flower at this season, the dry atmosphere of the flowering house being positively killing to them, in addition to the strain on the plants that flowering entails. If once the pseudo-bulbs begin to shrivel it takes months to restore them to a plump condition, and the subsequent growths are always weaker in consequence. It is yet too soon to diminish the shading on any of the houses, any plants that require more sunlight being preferably shifted to where this is obtainable without endangering the others. Continue to keep the growth clean and allow no check of any kind. Should damp weather set in a little fire heat would again be necessary, as it is important that a little ventilation should be kept in even the warmest houses by night as well as day.

***Epidendrum cochlearatum*.**—I have called in at the Chelsea nurseries of Messrs. James Veitch and Sons at various seasons of the year and cannot recollect not finding this rather pretty species of *Epidendrum* in flower. It is said to be the first of the genus that flowered in this country and is mentioned in one of the editions of Miller's "Gardener's Dictionary." The yellowish green sepals and petals contrast curiously with the lip, internally streaked with maroon, the outer surface being coloured rich maroon. Except in colour, it does not differ from *Epidendrum fragrans*, figured in *Botanical Magazine* (tab. 152 and tab. 1669).—J. D.

***Cypripedium concolor*.**—This species was sent from Moulmein by the Rev. C. Parish some thirty years ago, and flowered in the year 1865 with Mr. Rucker and Mr. Day. Sir Joseph D. Hooker writing about it says "It seems to grow and flower as freely, and to be managed with as little difficulty as the other Indian *Cypripedia*." Doubtless this was written after a year or two years' experience only, for it was soon found that this and allied species were much more difficult to cultivate than *C. villosum*. For instance, Mr. Parish was careful to state that he found *C. concolor* growing on lime-stone rocks. In 1870 *C. niveum* was imported, followed by *C. Godefroyi* and *C. bellatulum*. They are mostly

found on calcareous rocks. This, of course, gives one some idea of the treatment they ought to receive. They have been grown well in loam from the limestone formation, with plenty of small pieces of limestone mixed with it, the plants given plenty of heat and a moist atmosphere. The other day I saw it growing well in the Royal Exotic Nursery at Chelsea in nothing but nodules of tufa, which consists mostly of carbonate of lime. It was interesting to see the roots running healthily over the tufa, the plants developing healthy green leaves.—J. DOUGLAS.

## FLOWER GARDEN.

### THE ROCK GARDEN.

#### XI.

JUNE 22.—Rock gardens everywhere have donned their best and brightest summer garb. The prevailing flowers of the week are still the many varieties of *Dianthus* and *Campanula*, but as I have already mentioned these in my notes of last week, I will pass them by and enumerate others that have come into bloom during the last fortnight or so, and might be associated in such a way that their colours would blend harmoniously.

#### BRIGHT CARPETS OF FLOWERS.

Under this heading I will devote a few lines to such dwarf rock plants as are now in bloom, and are either of a prostrate habit or are adapted for massing together in such a way as to form a carpet over soil and stones on which here and there medium-sized and taller plants might be shown off to better advantage. The various forms of *Thyme* now in full blossom are useful. A very effective combination is formed by intermingled groups of the white *Thymus Serpyllum albus* and the so-called red *Thyme* (*Thymus Serpyllum coccineus*) contrasted against bright yellow flowers such as, for instance, *Genista humifusa* or *Coronilla iberica*, whose prostrate shoots would cover the stones as quickly as the *Thyme*. The woolly *Thymus lanuginosus* has not an attractive flower, but since its peculiar fluffy appearance is its greatest charm, this is of little consequence. It suffered severely during last winter, and in many places got killed altogether with the frost. *Aubrietias* have mostly passed out of bloom, but the finest of them all—namely, the purplish crimson *A. Leichtlini*—is still at its brightest, and associates well with the yellow *Cheiranthus alpinus* and the white *Gypsophila repens* or the prostrate double form of *Silene maritima*. A very beautiful rock plant of decumbent habit is the white *Antirrhinum glutinosum*, which should be allowed to droop gracefully over the stones and be associated with plants like the crimson *Epilobium obovatum*, the magenta *Callirhoe involucrata*, or the pink *Geranium cinereum*, all of which are now blooming profusely. *Alyssum spinosum* with white flowers is of not so spreading a habit as some of its congeners, and looks exceedingly well associated with blue *Campanulas* or the pink *Acantholimon glumaceum*. *Anthemis Griesbachii*, another white flower, much resembles *A. Aizoon*, but its leaves are a little broader; it associates well with *Gentiana cruciata*, now in full bloom, and also with the very dwarf yellow *Oenothera punila*. Very neat plants are the pink *Saponaria cespitosa* and the yellow *S. lutea*, while for a quick growing carpeting plant few can surpass *Silene alpestris*, with its bright green dense cushion of leaves and pure white flowers. The pretty alpine *Toadflax* with dark purple flowers and orange throat is flowering

profusely this year, and on a sunny bank goes well with the numerous Sedums and Sempervivums now in bloom. Its flowers, as well as its small glaucous leaves, form a most striking contrast to the dark brown rosettes of Sempervivum triste or the brown foliage and yellow flowers of Sedum rupestre. Of other Sedums and Sempervivums now in bloom I might mention Sedum kamtschaticum, with alternate green leaves and umbellate cymes of deep yellow flowers; Sedum spathulifolium, with glaucous rosettes and bright yellow flowers, and the well-known Sempervivum Gaudini, S. arvense, and S. Laggeri.

Before closing my remarks on dwarf plants I must not omit the numerous varieties of Iceland and alpine Poppies in their glorious shades of scarlet, orange, yellow, pink and white which are just now at their best. These Poppies associate splendidly with Campanulas, and a group of rocks reserved exclusively for Campanulas and Poppies at Newton Abbot has been a most ornamental feature for several weeks past, and will probably continue to be attractive for several weeks more.

I have suggested only a few of such combinations of plants as would be effective by way of contrast, but it will be obvious that the scope for artistic grouping must be practically unlimited.

MEDIUM SIZED PLANTS NOW IN BLOOM.

Without medium-sized, and even now and then tall, plants introduced in suitable positions, rock gardens would lose much of that peculiar wild charm which should be one of their most essential features. I will here mention such of the medium-sized plants as have been in bloom for the last fortnight or so: Heuchera sanguinea (red), Chrysobactron Hookeri (yellow), Anthericum Liliago (white), A. liliastrum (white), Oxytropis strobilacea (lilac), (Enothera marginata (white), Linum flavum (yellow), L. narbonne (blue), Armeria cephalotes alba, Aquilegia pyrenaica (blue), Scutellaria alpina (violet with white under lip), Erigeron philadelphicus (mauve), Erodium macradenium (pale mauve with purplish black veins and spots), Chrysanthemum Zawadskyi (pale pink, yellow centre), Scabiosa Webbiana (creamy white), Funkia japonica aurea, F. j. luteo-marginata, Polygonum Brunonis (pink), Veronica candida (blue), Prunella grandiflora (red), P. g. alba (white), Dianthus barbatus magnificus (armine) and Cynoglossum apenninum, with brilliant blue flowers. Last, but not least, I would mention that splendid Hawkweed, Hieracium villosum, with its large yellow flowers and shaggy leaves.

DWARF ROCK SHRUBS IN BLOOM.

Veronica Colensoi has escaped the severe winter and is now a mass of white blossoms. Helianthemums also are still in full bloom, most conspicuous being the scarlet H. venustum, the crimson Rosy Gem, and the bright yellow H. lunulatum. A very dwarf and compact shrub in full bloom at the time of writing is Spiraea bullata (crispifolia), and the bright crimson Alpine Roses, Rhododendron ferrugineum and R. hirsutum, though past their best, are nevertheless still attractive. Raphiolepis ovata has not suffered here from the frost, and its white blossoms are now as beautiful as ever. The tiny Fuchsia pumila and the elegant Hedysarum multijugum must also be mentioned as effective shrubs.

TALL PLANTS IN BLOOM.

Many of the taller kinds of hardy perennials form most effective backgrounds in the rock garden or as isolated specimens, and of these

I will mention the most suitable, according to their colour.

WHITE.—Anemone pennsylvanica, Lupinus polyphyllus albus, Campanula persicifolia alba grandiflora, Chrysanthemum maximum, C. semi-duplex, Epilobium angustifolium album, Anemone rivularis, Achillea The Pearl, Campanula macrantha alba, Bocconia cordata, Clematis erecta alba, and (Enothera speciosa.

BLUE.—Delphinium in great variety, Baptisia australis, Scabiosa caucasica connata, Platycodon grandiflorum, Echinops ruthenicus, Campanula Louis van Houtte and other Campanulas mentioned last week. Pentstemon ovatus, P. heterophyllum, Polemonium in variety.

YELLOW.—Centaurea macrocephala, Centaurea ruthenica, Genista tinctoria, Solidago virgaurea, Achillea aegyptiaca, A. Eupatorium, Scabiosa ochroleuca, Bupththalmum salicifolium, Inula glandulosa, Inula Hookeri, Gaillardia, Helianthemum pumilum, Lupinus arboreus, Senecio doronicum.

RED.—Pyrethrums of sorts, Lychnis chalconica, Geum coccineum, several Potentillas, Achillea Millefolium rosea, Papaver orientale in varieties.

PURPLE.—Erigeron speciosus, Geranium pratense, Geranium balkanum and Geranium armenum. The latter is of very compact growth and has large flowers of the brightest purple.

F. W. MEYER.

Ecce.

(To be continued.)

FLOWER GARDEN NOTES.

FOLLOWING up the notes lately made in connection with herbaceous and summer bedding plants as to those best suited for flourishing in such a prolonged drought as we have experienced in 1895, I may mention a few annuals that have come satisfactorily through the ordeal without any artificial watering. Cosmos bipinnatus in variety is a capital dry-weather annual. It is remarkable that the foliage should retain its healthy green, and that flowers of really good size and substance should be produced so freely from parched soil. Plants are nothing like so vigorous as in 1894, possibly no more than three-fourths the height, but the healthy appearance and free-flowing properties are well maintained. Exactly the same remarks apply to the varieties of Malope grandiflora, plants of which are at the present time flowering very freely. Individual flowers possess the merit of retaining their freshness out of water a considerable time; indeed, the bloom will show no signs of dropping even if the stalk is comparatively dry and withered. Both the above annuals are capital subjects for cutting, and it is, therefore, gratifying to chronicle their success in a season like the present. Gaillardias sown at the end of March, pricked out the end of April, and transferred to summer quarters as strong established plants, are also looking well and flowering freely. One has only to look at the profusion of Poppies in the corn fields to realise what capital dry-weather plants they are. Possibly no single flower has come more rapidly to the front for cutting than the various forms of Poppies, and a dinner table well done with judiciously selected colours thinly arranged among spreading panicles of Gypsophila paniculata is hard to beat. I said in last week's notes that herbaceous plants on dry borders were feeling the effects of the prolonged drought, and am sorry to say in such positions the Spiraeas have completely collapsed; good spikes of flower will be very scarce. Passing by some large clumps of Hemerocallis that have been naturalised in a fairly moist spot in the pleasure grounds, I had the curiosity to pick a single flower to compare it for size and substance with the blooms on herbaceous borders running through the kitchen garden, and found it quite one third larger in size, the individual petals altogether firmer and thicker. The obser-

vation thus made applies to all families liable to be affected by want of water, such as Lychnis, Phloxes, Pyrethrums, as well as the various forms of Lilies, besides the Day Lily above named.

TUFTED PANSIES.—Anxious to secure at any rate a small percentage of cuttings, I have this week gone carefully over the beds of tufted Pansies, removed everything in the way of seed-pods and dying blooms, pricked the surface very slightly with a small fork, and gave a thorough soaking of water. If this is not conducive to the production of cuttings that will be large enough to enable early insertion, it will at least encourage growth to warrant a more extensive splitting up in the later propagation by division. This latter style of propagation will have to be more generally adopted than is usually the case, at any rate on all light dry soils. Here for instance I strike all the stock for the coming year as a rule from cuttings, but a close inspection of many varieties at the present time fails to furnish anything like the amount required. It is useless inserting cuttings late in the season; there is not the time for the making of good plants, and they dwindle away on the approach of severe weather. Given well-rooted plants, the proportion of loss is, on the other hand, phenomenally small whether they remain through the winter in the cutting frame or are transferred to permanent quarters some time in October. Personally I should always advocate autumn planting alike for tufted Pansies and summer-struck Carnations, Pinks, &c. Writing of Carnations reminds me that the grass has come on wonderfully in the last fortnight, and preparations for layering must be pushed forward, as the chances are that the flowering season will be comparatively short. Our losses on the Carnation beds were much heavier than usual, about one in twelve failing, but those that remained have done remarkably well, being large plants and throwing a fine lot of flower. Countess of Paris, Mrs. Reynolds's Hole, Goldfinder, Sir Beauchamp Seymour and Murillo are at their best; other sorts grown, as Ketton Rose, Raby, and a pink deeply serrated Clove, are yet to come out. The different forms of Clove suffered more than the others, possibly owing to the more succulent grass.

POLYANTHA ROSES.—Some three years ago a border in the flower garden running under a north wall that had been cleared of a lot of old shrubs was planted with Polyantha Roses in variety, and in a season like the present we have no more beautiful or useful bed. It is not that they are so much more free; all the families have flowered well, but the position is answerable for a long retention of individual trusses and flowers, a rather unique experience for 1895.

E. BURRELL.

Claremont.

Chrysanthemum lacustre.—I have now in full bloom at my seed grounds at Bedford a broad line of this plant 20 feet or so in length. A more showy white-flowering hardy plant for border decoration at this season of the year, or for cutting from, I do not know. It was sent to me a few years ago by an old Lancashire botanist, Mr. James Percival, Smithy Bridge, Rochdale, as the true Chrysanthemum lacustre, it being his way of protesting against a statement which appeared in one of the gardening papers that C. lacustre is but a synonym of C. latifolium or maximum. Really it is more closely allied to C. leucanthemum, of which I regard it as a glorified form growing about the same height, and, like it, very free of bloom. In habit of growth it represents C. leucanthemum, but is more robust. I notice that on page 455, Mr. E. Burrell writes of C. maximum as an "autumn flowering perennial Marguerite." I have plants of it in several positions, and where they are most favourably placed they are only just commencing to throw up their flowering stems. C. lacustre is now in full bloom and appears likely to be at the end of it almost before C. latifolium is coming into flower. I notice that Mr. Burrell states C. maximum, which I take to be the same as C. latifolium, requires annual removal on a light dry soil. I have C. lacustre on both light and heavy ground, and it does admirably in each, growing into

larger plants and not in any way needing annual removal. On referring to Messrs. Barr and Son's recently issued list of herbaceous perennials, I find they make *lacustre* a synonym of *C. latifolium* and as flowering in September and October. In Nicholson's "Dictionary of Gardening," neither *lacustre*, *latifolium* nor *maximum* find a place as species; so it would seem as if a great deal of confusion exists among the different forms. Messrs. Barr and Son give *leucanthemum grandiflorum* and several varieties of *maximum*, the time of blooming of the last being from June to August.—R. D.

### ONOSMA TAURICA.

(GOLDEN DROP.)

This is one of those choice subjects which in the majority of gardens does not attain to a very great age. In the ordinary course, plants of a few years old die off quite suddenly and without apparent cause, but upon examination the collar is generally found in a state of decay. One of the best positions in which it can be planted is on a slightly raised rockery with a deep root-run of soil without manure. If possible plant it on its side, the under-side resting on a piece of rock, so that the growth may emerge therefrom, and cover the upper surface also with a piece of stone. The plants are invariably longer-lived when planted between two pieces of rock. It is a good plan to root a batch of cuttings each year and, instead of potting them, insert them in small fissures of the rock where there is soil sufficient for them. Such plants make more rapid headway in the open border during the first season, but with the greater vigour of growth are more liable to succumb to our average winters. The only way I know of increasing this plant is by cuttings, as the plant cannot be divided and seeds are not obtainable. Cuttings may be inserted at any time during July, which month I regard as the best in the whole year. To secure the cuttings intact it will be necessary to strip them carefully from the old plant with a heel attached, and insert them firmly in very sandy loamy soil in well-drained pots. Some little care will be necessary to make the cuttings stand erect, owing to the short nature of the growths; indeed, I have upon more than one occasion found it necessary to tie some of the shortest cuttings to small pegs of wood to fix them in position. It is also important that the heart of the cutting is not covered with soil, but this is easily avoided by using the wooden pegs above noted. I never make use of the knife in preparing these cuttings, but insert them just as they are removed from the old plant. While in the cutting state nothing seems to suit so well as a hand-light in a cool shady position. Artificial heat should never be employed; it is fatal. If fresh young growths about 4 inches long are secured at once and inserted quite firmly around the inside of some 5-inch pots, there should be little trouble in obtaining a good batch of young plants. I prefer the earliest made growths of the current season, or where the plants have flowered there will be some cuttings about the base of the flower-stem that will prove excellent. While yet in the cutting state, any after-watering that may be needed should be carefully done. By watering thoroughly over-night and allowing the light to remain off till the following morning no damping will be likely to ensue. When it is intended to pot the rooted cuttings this should be done as soon as possible, avoiding a rich soil. A sandy loam with broken brick rubbish added, together with a small proportion of peat in small nuggets, suits the plant well. If

at hand, charcoal nuts with loam and leaf soil form a good mixture, this with firm planting invariably securing good results. Pot plants should never be wintered in a low, close, stuffy frame or pit, but by keeping dry at the root, near the glass, and clear of frost the plants will be much safer. Large specimens of this *Borage-wort* in the open border are rare, but upwards of twenty years ago I saw a large plant in the long herbaceous border at Hale Farm Nurseries, Tottenham. This was fully 18 inches across, and a dense tuft of growth. E. J.

### HYACINTH NAMES.

Why do so many distinct varieties bear the same names? These synonyms are not only ridiculous, but increase errors, and puzzle and disappoint buyers. Really these duplicate names ought to be changed. The following list includes the leading duplicate names; No. 1 is that by which the variety is most generally known, the others ought to be suppressed:—

- { 1. Charles Dickens, single dark blue.
- { 2. Charles Dickens, single rose-pink.
- { 3. Charles Dickens, single pale striped lilac.
- { 1. Gœthe, double light yellow.
- { 2. Gœthe, double rose.
- { 1. Grand Vainqueur, single white.
- { 2. Grand Vainqueur, double white.
- { 1. Grande Vedette, single white.
- { 2. Grande Vedette, double blue.
- { 1. Grand Monarque, double white.
- { 2. Grand Monarque, single rosy white.
- { 1. Heroine, single yellow.
- { 2. Heroine, double white.
- { 1. Jenny Lind, double white.
- { 2. Jenny Lind, single white.
- { 1. Lady Derby, single white.
- { 2. Lady Derby, single light blue.
- { 1. L'ami du Cœur, single red.
- { 2. L'ami du Cœur, single blue.
- { 3. L'ami du Cœur, single violet.
- { 1. Lord Wellington, double blue.
- { 2. Lord Wellington, double rose.
- { 1. Shakespeare, double red.
- { 2. Shakespeare, double blue.

D. GUIHÉNEUF.

### EVERGREEN BORDERS OF HARDY FLOWERS.

The plants of the older kind of mixed border were—like the Grasses of the meadows of the northern world—stricken to the earth by winter, and the border was not nearly so pretty then as the withered Grass of the plain or copse. But since the revival of interest in hardy and alpine flowers and the many introductions of recent years, we have a great number of beautiful plants that are evergreen in winter and that enable us to make evergreen borders. The great white blanket that covers the north and many mountain ranges in winter protects also for months many plants which do not lose their leaves in winter, such as Rockfoils, Stonecrops, Primroses, Gentians and Christmas Roses. The most delicate of alpine plants suffer when exposed to our winter from excitement of growth, to which they are not exposed in their own home, but it is easy by good choice of beautiful things to make delightful borders wholly or in greater part of evergreen hardy plants.

These are not only good as evergreen, but they are delightful in colour, many of them covering the ground with carpets of delicious verdure, many being beautiful in flower and having also the charm of assuming their most refreshing green just when other plants are losing their leaves or dying down. Along with these numerous alpine and herbaceous plants we may group a great many shrublets that come

almost between the tree shrub and the alpine flower—little woody evergreen creeping things like the dwarf Partridge Berry, Canadian Cornel, hardy Heaths, Sand Myrtles, and the Thymes.

Between these various classes we have plenty of material for making evergreen borders, and this is important, because, while many might object to the rawness of the ordinary border made of herbaceous plants as being too much in evidence near the house or in other favoured positions, it is quite a different thing with borders of evergreen plants, which may be charming and natural in effect throughout the year. It is not at all necessary that borders should be entirely devoted to the evergreen plants in order to get their good effects, because many of them, like the dwarf Rocky Mountain Phloxes and the evergreen Candytufts, make pretty dwarf edgings and masses, which vary ordinary mixed borders in a very effective way.

Of garden pictures, there are few prettier than Crocus, Snowdrops, or Scilla coming through the green, Moss-like carpets in these evergreen borders, far better for those who love quiet and natural colour than more showy effects. These quiet green borders also contrast well with richly stored, handsome borders, and are good near the house. Often narrow evergreen borders are the best things that can be placed at the foot of important walls (meant for climbers), as the common fashion of allowing Grass to go right up to the walls and houses is a foolish one, and often leads to injury to the trees. A narrow border (18 inches will do), cut off with a natural stone edging from the Grass or walk, is best: even a border of this size may have many lovely things, from early Cyclamen to the rarer Meadow Saffrons in the autumn. Besides the flowers already named, we have Violets, Periwinkles, Yuccas, Carnations, Pinks, white Rock Cress, Barren-worts, charming in foliage, purple Rock Cresses, Omphalodes, Iris, Acanthus, Indian and other Strawberries, Houseleeks, Thymes, Forget-me-nots, Sandworts, some Gentians, Lavender, Rosemary, hardy Rock Roses, and many native and other hardy evergreen Ferns in all their fine variety; these are an essential aid in the making of hardy evergreen borders.—*Field*.

**Lavatera trimestris.**—From a packet of seed of this I get especially bright and pale rose forms as well as pure white. Where the plants are employed in the summer bedding arrangements it is well to have the various colours in separate packets. I employ the rose-coloured forms for mixing with white and yellow Marguerites. These along with blue Cornflowers make a pretty and effective summer display.—E. M.

**Asclepias cornuta**, a vigorous growing plant, though hardly good enough for a border of choice flowers, is effective when rightly placed, and arrests attention by its distinctness. We saw a mass of it at Broxbourne, the tall leafy stems bearing great umbels of sweet purple flowers, which have a great attraction for bees. It could easily be naturalised in a light free soil, and one would enjoy it more by seeing it holding its own among the natural vegetation.

**The single Hollyhock.**—The disease and other troubles that attend the growth of choice double Hollyhocks have brought them into disrepute, but we think the single Hollyhock is worthy of more attention as a garden flower, because it can be so easily raised from seed and treated generally as a hardy biennial. The single forms have all the stately majesty of those with double flowers, and they could be used most effectively in gardens. We have seen some lately in cottage gardens in Hertfordshire and Essex, and their beauty was great.

PHORMIUM TENAX AT FOTA.

As will be seen from the engraving, the New Zealand Flax is growing on the edge of a pond, a situation which it enjoys with its roots running into the water several feet. Phormium tenax and its several varieties—tenax variegatum, Veitchi, Coleensoi and atro-purpureum—are planted largely here, and most of them on the edge of shallow ponds or land that has been reclaimed from the sea. The compost in which they grow and thrive is chiefly mud and fish shells. This mud has been brought in by the tide, and as the water recedes a deposit is left behind. By building sea walls and banks to keep out the sea water the land has been covered with a sub-tropical vegetation, including New Zealand Flax (Phormium tenax), Arundo conspicua, A. donax, Pampas Grass, numerous Bamboos, Gunnera manicata, G. scabra, &c.

Fota.

W. O.

TURK'S-CAP LILIES.

By Mr. Baker the genus *Lilium* is divided into five sections, that containing the greatest number of species being the sub-genus *Martagon*, the members of which are characterised by drooping blossoms with gracefully recurving segments; hence the term Turk's-cap, which is applied to many different species belonging to this section. One of the commonest species—and that which gives its name to the group—is *L. Martagon*, of which there are several varieties in cultivation. The common *Martagon* has flowers of a dull purplish or lilac-purple tint, with dark coloured spots on the inside. Though extremely graceful the flowers of this are, at best, dull. A well-marked variety is *dalmaticum*, whose blossoms are of a deep blackish-purple hue, that is when a good form is obtained, for in colour individuals vary a great deal. In direct contrast to this we have the white variety, perhaps the most striking of all the *Martagons*. The flowers of this are white, tinged with green on the exterior towards the base of the petals, and a charming outdoor Lily it is. The term "outdoor" will apply to all the forms of this species, as the blossoms have such a heavy, unpleasant scent that by many they cannot be tolerated in a confined space. This feature is also very prominent in a Lily commonly known as the Yellow *Martagon*, which is, however, a distinct species, viz., *L. pyrenaicum*, the first of all Lilies to flower in the open ground. The stem of this is very sturdy and plentifully furnished with narrow leaves, which are not disposed in whorls, as in the true *Martagon*. The flowers of *L. pyrenaicum* are of a greenish yellow tint, but there is a variety, *rubrum*, with reddish blossoms. This has more than once been made to do duty for *L. pomponium*, which is quite different, the flowers being of a rich sealing-wax red. It is more slender in growth than *L. pyrenaicum*, and can be distinguished from all others when but a few inches high by the dark green leaves having a narrow white margin. *L. pomponium verum* is the name under which this is generally known. The scarlet Turk's-cap is *Lilium chalcedonicum*, whose bright vermilion-red blossoms are not borne till July. It is particularly valuable as being one of the last of this group to flower, and derives especial interest from the fact that it is one of the parents of the distinct nankeen Lily (*L. testaceum*), *L. candidum* being the other. Other species belonging to the Turk's-cap group are *L. Hansonii*, a native of Japan, with leaves in whorls as in the common *Martagon*, and yellow flowers dotted with brown. This is particularly fine during the present season, especially at Kew, and it was also well shown at the meeting of the Royal Horticultural Society on June 25. At the same time an award of merit was bestowed upon a very curious and most interesting hybrid—*L. Dalhansonii*, whose parents (as indicated by the name) are *L. dalmaticum* and *L. Hansonii*. *L. monadelphum*, or *L. Szovitzianum*, as it is often called, belongs also to the same group as

the preceding. The drooping blossoms of this are for the most part of a primrose tint, spotted more or less in the interior, but in colour this Lily varies considerably. Others are the Indian *L. polyphyllum*, of a whitish ground with purple spots; *L. tenuifolium*, something like a miniature pomponium; *L. Leichtlini*, one of the most graceful of Lilies, the flowers of which are of a straw-colour plentifully dotted with reddish brown; and *L. testaceum*, of a pleasing nankeen tint. This is a Lily that should be far more frequently grown than it is at present. All of the above succeed best in a deep loamy or ordinary garden soil, and they are all impatient of removal; indeed, many of

very generally grown. These last are all natives of North America, and another very showy species is *L. Humboldtii*, which comes from the same continent. A sandy loam suits the requirements of this Lily best. H. P.

**Hardy flowers at Forest Hill.**—These are now largely grown by Messrs. Laing and Son in the nursery at Forest Hill, and when there recently we made note of several things in the open quarters that were enduring the drought and making a good display of colour. *Achillea Eupatorium* and the equally sweet, but less grown *A. filipendula* were both

of our wild *A. millefolia* is not to be despised. *Malva moschata alba* was flowering freely, and *Delphiniums* in great variety were also conspicuous. *Helenium Bolanderi*, an early and showy dwarf kind, made a bright group, and *H. pumilum*, equally dwarf and free, promised a long succession of flowers. A mass of *Pentstemon barbatus* was bright. It is a pity that more do not plant this, as a good group yearly can be ensured by pulling off the side shoots, potting them up for a few weeks, and planting them out again when well rooted. The plant is worthy of this little care; whereas, if left alone, as most hardy plants are, it is less satisfactory. *Chrysanthemum maximum* in several varieties we saw in large quantity, and there is no better flower of the present time for cutting. Among many alpiners growing in pots we noted *Campanula garganica* in trailing masses covered with flowers, and a variety of this species named *hirsuta* equally free flowering, the leaves and stems alike clothed with short hairs. *C. turbinata* was also conspicuous. There are few better dwarf *Campanulas* than this for the rock garden.

**Notes from Oakwood.**—*Meconopsis nepalensis* is doing very well at Oakwood. It is grown in partial shade and in rather a damp, very sheltered place. There is something very pleasing about this *Meconopsis* when in really good condition. *Coronilla varia* is a very free-growing, profuse-blooming species with soft pink flowers. It is one of those things that should have plenty of space and an open position. When it forms a mass some feet through it has a very pleasing appearance. What a dainty little flower is *Primula scotica*, growing some 2 inches in height, with mealy foliage and purplish blooms! It is, I believe, difficult to please, in southern gardens at least, but appears to have come to stay at Oakwood. *Arenaria loricifolia*, with white flowers and narrow leaves, is a pretty species; it is one of the best of the family. In a damp, rather shady place *Galax aphylla* is doing remarkably well. The spikes of white flowers thrown up boldly above the prettily formed leaves and the very compact habit render this *Galax* one of the most distinct of hardy flowers. It evidently enjoys moisture both at the root and in the air, and presumably dislikes hot sunshine. *Nerophyllum asphodeloides* is decidedly handsome, and worthy of a place in any collection of hardy flowers. If this could be had in sufficient quantity and would thrive under ordinary culture, it would be a capital thing for dotting among dwarf-growing bedding plants. A mass of the large Cranberry (*Oxycoccus macro-*

The New Zealand Flax at Fota. Engraved for THE GARDEN from a photograph sent by Mr. Smith, Clarence Lodge, St. Luke's, Cork.

them frequently fail to flower the first season after being transplanted. Where they are doing well it is advisable to leave them alone. *L. chalcedonicum* (the Scarlet Turk's-cap) is sometimes met with associated with *L. candidum* in fine masses in old-fashioned cottage gardens.

A very distinct section of the sub-genus *Martagon* consists of several species with curious rhizomatous bulbs, which succeed well in a peaty soil, though it is not absolutely necessary to their well-doing, for I have seen good examples in loam. The best known of these are *L. pardalinum*, *L. canadense*, and *L. superbum*. They are all beautiful species, and *L. pardalinum* in particular is now

of the best of the family. In a damp, rather shady place *Galax aphylla* is doing remarkably well. The spikes of white flowers thrown up boldly above the prettily formed leaves and the very compact habit render this *Galax* one of the most distinct of hardy flowers. It evidently enjoys moisture both at the root and in the air, and presumably dislikes hot sunshine. *Nerophyllum asphodeloides* is decidedly handsome, and worthy of a place in any collection of hardy flowers. If this could be had in sufficient quantity and would thrive under ordinary culture, it would be a capital thing for dotting among dwarf-growing bedding plants. A mass of the large Cranberry (*Oxycoccus macro-*

carpus) growing in a boggy place has a nice appearance. *Azalea rosiflora*, growing in company with *Rhododendron Assamæflora* in a sheltered position, passed safely through last winter.—J. C. B.

**Campanula persicifolia alba.**—It will be generally admitted that the white varieties of this group of Bellflowers are among the most useful of hardy perennials. Quite recently I was looking round a border of hardy perennials where Phloxes, summer-flowering Chrysanthemums, Roses, Dahlias, Christmas Roses, Clematis, Aubrietias and other things were to be seen, but just at the time to which I refer nothing could compare with the snowy purity of some masses of the *Campanula* named above. It was just in its prime and constituted the plant of the hour. Indeed, but for this particular plant, which was arranged in large clumps at intervals, there would have been an overwhelming presence of greenery in the instance referred to. The white varieties of these Bellflowers in common with the majority of the genus are readily increased. Where quantity is needed, and that quickly, it will be found much the best plan to select a good-sized clump in the early spring and, pulling it to pieces, pot the divisions, or at least those having roots attached, singly into 3-inch pots. These may then be placed in a frame or at the base of a shady wall to become established, and when this happens plant out in beds or masses as required. A fair depth of quite ordinary soil with some manure added is all that they require, and when planting do it firmly. Where only a few clumps are required the usual methods of division and firm planting will answer well. These white Peach-leaved *Campanulas* have, however, quite a special merit of their own, and with advantage may be planted in many spots in the foreground of shrubs, producing a fine effect. There are at least three distinct white kinds apart from that named above, which is the white form of the type, namely, the great white Peach leaved Bellflower (*C. p. a. grandiflora*), a taller plant with very large white bells; *C. p. alba plena*, the well-known double white, and *C. p. alba coronata*, a kind by no means common, yet one of the most beautiful of the group. With four such excellent varieties there need be no lack of pure white flowers in the herbaceous borders in early summer. With the exception of *grandiflora*, which attains 2½ feet to 3 feet high, the others are usually about 2 feet high when established.—E. J.

#### CARNATIONS AT CHELSEA.

There is plenty of evidence that the Carnation is a good town flower, and the tufts of the old Clove along the Embankment Gardens when gay with flowers prove this. Messrs. Veitch annually have a good display of Carnations at Chelsea, which is the more creditable, because considerations of space compel them to follow the usual custom of wintering the plants in frames, planting them out where they are to flower in early spring. There are advantages in favour of this plan, for whilst gaps are decidedly too frequent in plantations made last autumn, those of the spring months have fewer blanks. Some of the self-coloured kinds are very good at Chelsea this year, and we note with pleasure that not a few of them are recent varieties of English origin, and possessed of all the essential qualities that are necessary in a good garden Carnation, namely, that they are robust, vigorous, and bear fine non-splitting flowers of clear and decided self colours and pleasant fragrance. This last most charming attribute of the flower is unfortunately too often absent, but the variety *Cantab*, one of Mr. Gifford's raising, is, we should think, next to the old Clove, one of the sweetest garden Carnations. A bed of it at Chelsea was very bright. *Duchess of York*, also raised by Mr. Gifford, was very good, the flowers of a pale flesh tint. Mrs. Frank Watts, a variety from the same raiser,

was in good form, the flowers numerous and not bursting. Mrs. Fred growing beside it is also a very good white self, which finds most favour among those who show, being of the form so dear to the florist with its regular and smooth petals. The varieties Mr. Martin Smith has raised were very prominent. *Aline Newman* is one of the first, but not yet surpassed in its special shade of soft cerise-red, whilst the plants were as vigorous in growth as they were free-flowering. Mrs. Audrey Campbell was strong in growth, with extra tall flower-stems carrying fine, rich yellow blooms. *Hayes Scarlet*, brilliant in colour, perfect in form, and robust in growth, is all that can be desired, and *Mephisto* is quite its counterpart except in colour, this being a dark shade of crimson, rich and striking. *King Arthur* has an immense flower as large as that of a *Malmaison*, yet good in form, held up erect, and of a bright red colour. *Duchess of Fife* was very good, and *Lady Nina Balfour* remarkably fine, as it carries its flowers well on a strong stem and they are of the softest flesh-pink shade. It is undoubtedly a grand new Carnation. *King of Crimson* and *King of Scarlets* were both good in their respective colours, and *Oxonian*, a fine dark crimson self, we noted as being distinct and effective. *Cara Roma*, dark maroon-purple, was free-flowering and very fine, of a dark and pleasing hue. Among older kinds several were very conspicuous, especially *Joe Willett*, which stands the bright hot sun well, and a large bed of this variety alone was very showy. *Rose Celestial* was unsurpassed in its special shade, and the old buff-yellow *Florence* we have not seen for a long time so free and good as here. A bed of *Alice Ayres*, too, was without a blank and as effective as any self variety.

#### PICOTEES

were very good, although the differences in the varieties are so small, that they are nothing like so important as the selfs for effect in the garden. *J. B. Bryant*, a well-known crimson edged variety, was good, also *Brunette*, which has a broad edging of crimson, and *Ganymede*, edged with dark crimson. Among varieties of a lighter tint, *Favourite*, also a well-known kind, was first-rate, the petals having the merest line or edging of light rose. *Edith Donbrain* and *Mrs. Sharpe* were good. These are rose-edged varieties of a deeper and heavier character. *Lorna Doone*, a pretty rose-flaked kind, was seen in good form and colour, but doubtless owing to the heat and drought a large percentage of the flaked and bizarre varieties are producing self-coloured flowers.

#### A BATCH OF SEEDLING CARNATIONS.

In the warm summer two years ago I was fortunate to save some Carnation seed from various sorts—*Countess of Paris*, *Redbraes*, a fine pink and purple-striped one of good habit, *Germania*, Mrs. S. Reynolds-Hole and some others of less note, also a large heavy scarlet called, I think, *Danger*. I separated all the *Countess of Paris* seed from the rest; I am sorry I did not separate every kind, as it would have assisted study.

The batch from *Countess of Paris* numbers fifty-five plants. In habit they are all strong and similar to the parent, or stronger (of course young seedlings are always strong), but in bloom they differ most remarkably. I was told by an old florist friend that the *Countess* repeated itself very much. I find not one blooming anything like the parent; one or two, perhaps, have nearly as nice shaped flowers, but the colour is pink-striped, crimson and purple. The extreme colour-sensitiveness of the variety is remarkable; one single and one double follow *Redbraes*. They will all bloom. Two or three are of a soft red

or scarlet, much reduced, only six are single Jacks; fifteen are purple or crimson, derived from other purple sorts that bloomed close by; eighteen or more are frightful bursters. I infer from this that it is a fine stock to work from, for by crossing it with any coloured sort, you will be sure to get it in the seedlings; but though you may expect a good habit you will have to take your chance of the shape and quality of the flower. Now for the mixed batch.

There were here about sixty plants of much more dubious constitution; in fact, the constitution of the parent is again generally repeated, but the colours are also much better followed; some are copies of the parent, but some again have evidently gone off in habit. The seedlings of *Germania* are yellow, but clouded with red. One, I think, will have yellow flowers, but it is weak in constitution. The entire batch shows scarcely any outside influence, and thus there is no purple, as in the *Countess*. The seed of *Danger* is one single and one poor double, but a soft inferior red has yielded several still poorer than itself. Mrs. Reynolds-Hole seems to have yielded a number, all poorer in every way than the parent. The tall pink-striped one has given one like itself somewhat, one beautiful single of a charming shade of red-pink, and one glorious white on long, separate stalks, and another tall pale pink one, each about 30 inches high. More single Jacks occur in this lot and still more have refused to bloom; thirty-six bloomed, twenty-three failed to bloom. They all wintered very well indeed, far better than any of the cultivated plants.

The general inference is to take seed only from plants of strong, good constitution and habit, and the particular point is that some sorts are far more colour-sensitive than others. I should think that *Countess of Paris* scientifically crossed with others would yield excellent sorts in every shade. Of course, our English climate is very bad for this work, yet potted plants in a house which is never closed at the sides will probably secure the result aimed at.

A. DAWSON.

*Godalming.*

#### **Begonia Worthiana in the flower garden.**

—I do not know of any variety equal to the above for the flower garden, and though the hot dry weather has prevented it making as free growth as usual, the mass of flowers is charming and a relief from the general run of bedding plants. Not only is *B. Worthiana* very free flowering, but the colour is none too plentiful in the flower garden. The plants are readily propagated by cutting the tubers with an eye to each shoot just when starting into growth. I prefer cuttings to seed, as they flower more profusely, are ready to plant earlier, and are more regular in height. When we consider what little trouble such plants as these give during the winter and their ready means of propagation with their beauty at this season, they are invaluable for the flower garden. I think *B. Worthiana* the best of the small-flowered section. The newer *semperflorens* is also very effective and readily raised from seed. Indeed, I like seedlings better than cuttings in this section. The white variety makes a charming edging to the *B. Worthiana*.—G. W.

**Pinks from seed.**—At the middle of the summer of 1893 I sowed some seed of laced Pinks from a fine collection and was rewarded with a number of seedlings. These were planted out in the spring of 1894, but scarcely one attempted to bloom. They were allowed to remain all the summer. They passed through the last winter, though I lost many of the named varieties, and this season they are blooming grandly, and among them are several good varieties. The plants had grown into larger clumps and they have borne remarkably heavy heads of bloom. Planted out in a heavy loam, which has baked very hard on the surface, they stand the heat well, and I presume the roots have gone down deeply into the soil. It is in this fact we recognise the importance the grower of laced Pinks attaches to autumn planting in order

that the plants may become well established by the time they flower in the spring, and it also shows that two-year-old plants are the best to throw a mass of bloom. A florist who grows for exhibition would naturally prefer plants from cuttings or layers of the previous summer, because it requires only two or three good blooms on a plant, disbudbing freely in order to secure them. Seedling Pinks are full of interest provided seed of a good strain can be secured, a matter of some difficulty. I notice that among some 120 plants in bloom there is scarcely a self white.—K. D.

ORCHARD AND FRUIT GARDEN.

GRAPE GROS GUILLAUME.

Those who have been fairly successful with Gros Guillaume speak highly of it, while those who for various reasons have either never grown it or have not succeeded in producing presentable bunches are ever ready to condemn it. A middle course would perhaps best meet the case. A really serviceable Grape it is not, but there are good qualities that ought not to be lost sight of. It is one of those Grapes that may be said to need special culture. In a house of mixed late varieties started into growth early in March Gros Guillaume is very liable to fail—at least, such is my experience, and I hold that to have it at its best it ought to be started a month earlier and treated as a midseason variety. Grown in a house with Black Hamburg and Madresfield Court, these ripening in June and July, the variety under notice would form an admirable succession to these popular varieties—that is to say, would be quite fit for use in September and October. Some think the flavour is considerably improved by keeping, say to nearer Christmas, but I have found the larger clusters keep badly when ripened thus early, and the quality has never been found fault with in September. Well grown it is a crisp refreshing Grape, and at that time of year only excelled by the two other varieties named when at their best, Muscat of Alexandria excepted.

Authorities are unanimous as to the desirability of grafting or inarching the Gros Guillaume on to the Black Hamburg stock. On its own roots it is apt to grow too rank to be productive; whereas the Hamburg stock has the same restraining influence as the Quince stock has upon the Pear. It unites very readily with that stock, and I have never known bottle grafting to fail. Fine rods are formed on the Hamburg stock, and if these are thoroughly well ripened, failures to show plenty of bunches are rare. It is the soft pithy wood that fails the most often, though there are other causes of non-fruited to be noticed. Gros Guillaume is principally grown in gardens where sensational bunches are desired. If we can be content with a few of these, all well and good; but if we leave enough of them on the Vines to overtax their energies, not only will the berries be small and foxy red in colour, but the chances are few or no bunches will appear the following season. Growing the variety on what is known as the long-rod system, young canes being laid in every season and those that have fruited once cut out, is to a certain extent a remedy for non-productiveness, but I fail to see the necessity for this. If over-cropping is avoided and very close pruning never resorted to, the old rods will continue to produce fine bunches for many years. Instead of pruning the laterals to the first bud it is better to sacrifice neatness of spurs and think more of what is of greater importance, viz., productiveness. Prune to a plump bud, whether

this be 2 inches or 4 inches away from the old wood.

If very large bunches are wanted, then, as before hinted, be content with three or four of these on a strong rod 12 feet or more in length. Take every pains with these, letting a fair amount of daylight and sunshine reach them, this, coupled with the maintenance of a buoyant atmosphere, ensuring a good set of berries. Under favourable conditions the bunches develop surprisingly, the uppermost shoulder resembling and equalling in weight and form an average bunch of Black Hamburg. There should be little or no thinning of berries at

That is by no means a clumsy, ugly bunch, while the berries could almost have passed as those of Black Hamburg, a thinness of bloom, and which is always apparent, being the only marked difference. Handsome, solid bunches weighing 3 lbs., or rather less, could always be had as thickly on a rod as good clusters are seen on Black Hamburg rods if only we could make up our minds to pinch off the larger "shows" that are produced nearer the spurs or canes, as the case may be. Should, however, no more than one bunch show on a lateral, it could soon be seen which promised to be large, and which moderately so, or only comparatively

small, and the selection be made accordingly. Much improvement might be effected in the shape of a bunch with the aid of a pair of Grape scissors, with these snipping off long, thin points and straggling shoulders. Any that are to travel to exhibitions, or to be packed for other purposes, must be fairly solid, otherwise they present but a sorry appearance when at the end of their journey; hence the necessity for a certain amount of trimming and also for very careful thinning out of berries, doing the latter piecemeal or as it is plainly seen what berries can best be spared. Remember also that medium-sized to small bunches evenly furnished with large well-coloured berries free of blemish will always surpass others double their weight, but lacking in other essentials. Labelling huge but badly coloured clusters "Barbarossa" will not mislead anyone. It may answer very well while yet they are hanging, but will have no favourable effect when experienced judges are called upon to adjudicate upon their merits.

Grape Gros Guillaume. From a photograph by Mr. J. Cooper, Jun., Frome.

first, but every shoulder and large division of bunch ought to be brought up to a horizontal position and kept so by means of strips of raffia. When finished there would be quite a network of ties, and this, in addition to giving the bunches an imposing appearance, also obviates the necessity for much thinning of berries, only the smaller berries, or enough to allow those furnished with three or more stones to develop to a large size, being cut out. As it happens, bunches 8 lbs. and upwards in weight are not of a serviceable character, and those nearer 6 lbs., such, for instance, as that represented on this page, are more to the purpose.

Muscat of Alexandria—and my best bunches have been produced in a Muscat house—abundance of air, or more than the Muscat may require, should be admitted at that end of the house, leaving a little front air on all night through. Give the same treatment as answers well in the case of Muscats, and foxy red berries, such as also result from over-cropping, will most probably be the outcome. I once saw twenty large clusters of Gros Guillaume ripening on a single Vine grown on the extension system, not one of which was ever good enough to send to the owner's table. Yet that Vine was raised from a reputedly good

stock, this showing that it was the cultivator's fault those bunches were of so little value. As a proof of this I have only to add that the same Vine, only less heavily cropped and also subjected to less heat, has produced bunches equal to taking prizes anywhere. If the bunches are to hang on the Vines late, then I prefer to have the roots confined to an inside border, but would rather have them rooting outside, when they can be started early and the crops cleared off before November. They stand plenty of feeding in either case. W. IGGULDEN.

**Apple Emperor Alexander.**—"W. G. C.'s" description of this fine-looking Apple is a faithful one, as he does not omit to mention its somewhat shy-fruited propensities. I quite agree with him that it requires careful cultivation, and instead of being rigidly pruned in, thinned out when young and shortened just a little at the winter pruning. Even under this treatment it will not thrive in all districts, and the fruit, though fine and beautifully coloured, is very soft and unfit for market, except when the sale place is near home. After seeing a magnificent dish of Alexander some years ago at Lincoln November show I was induced to plant it in espalier and horizontal form, but while the trees grow well enough and several moderate crops have been borne on the cordon, the espalier has never borne a single fruit. Perhaps time may remedy this barren condition, as I trust it may.—J. C.

**Gooseberry Leveller.**—This fine yellow Gooseberry belongs to the yellow show section of Lancashire varieties, and is, unlike many of its class, a most profitable sort to grow, even for a poor man. On our somewhat light soil Leveller fruits heavily, ripening about the end of July, and is then delicious for dessert. It hangs better than the majority of the large Gooseberries, which are so apt to split in changeable weather. If duly thinned out when young and a good mulch given to the roots, the same being well soaked several times with liquid manure, it will prove itself one of the best exhibition varieties in existence. Those who are fond of large Gooseberries, and would like quality combined, should certainly plant Leveller.—J. C.

**Two good Raspberries.**—The dry summer and the severe winter have again shown which are the two best Raspberries in what may be termed a poor, light soil. The two varieties alluded to are Hornet and Superlative, and if only one sort is grown I would certainly give Superlative the preference, as though Hornet is equally free fruiting, it is not so continuous a cropper. Some of the older kinds of Raspberries were destroyed, but the strong-growing kinds of the newer section are bearing splendid crops. The canes are a little shorter than usual, but this is compensated for by the quantity of bottom growths bearing freely; indeed, there is no loss, as the canes are furnished with trusses to the base of the plants, and will thus crop later than when the fruit is produced on the tops of tall canes. Now is a good time to assist the plants and strengthen next year's canes by giving a liberal mulch, in poor soils giving liquid manure. It is well to reduce the suckers to the quantity required, so as not to rob the plants.—G. WYTHES.

**Ronald's Late Duke Cherry.**—Many varieties of Cherries fail to crop well or grow in a satisfactory manner when grown as bush trees, but the above is an exception, as it will produce excellent crops of large fruit late in the season when grown in bush form and worked on the Mahaleb stock. Some contend that the Mahaleb stock is of little value, as trees worked thereon are soon worn out and have to be rooted out. In such cases it is not always the fault of the stock, but is owing to the lack of nutriment within reach of the roots, which, not extending far away, quickly exhaust the supplies. At the same time there are some sorts that will not succeed as bush trees on any stock, as they

gum and die back until they are an eyesore in the garden. The above variety appears to be well suited for growing as a bush, seldom showing any indications of gumming, cropping freely on heavy and light soils, its large red fruits being very acceptable. It must, however, be well fed if continuous crops of large fruit are desired.—W. G. C.

**Strawberry Latest of All.**—In many gardens the British Queen fails, and where such is the case I would advise a trial of Latest of All. It was awarded in 1894 a first-class certificate by the fruit committee of the Royal Horticultural Society for lateness and good qualities combined. I am planting the Latest of All largely, doing away with British Queen, which fruits only sparsely and suffers badly in severe winters in low, damp localities. For several seasons I grew Waterloo, but it does not possess the flavour a good dessert fruit should do and it was discarded. Jubilee was grown for two or three years and did well, being an enormous cropper, but this was soon ousted by Latest of All on account of its fine flavour. I admit it does not ripen well at the point. This is a defect in the British Queen, but it is far more vigorous, the fruit being very fine, solid, wedge-shaped, and freely borne. Young plants of Latest of All bear freely, and it will, I am sure, become a great favourite when better known. Latest of All is a seedling from British Queen, crossed with Helene Gloede, a large fruit of good flavour. To show the long cropping qualities of Latest of All, I have been gathering it for ten days from a north border and the plants will produce fruit for a week longer. It not only does well on a north border, but forces grandly. This spring I tried it for a late lot, and as forced in frames was much pleased with the result; the foliage is firmer than that of the Queen, and, being harder, is less subject to red-spider. This variety has now been four years before the public, and the more it is known the better it will be appreciated. It cannot be propagated freely, as it makes but few runners. From strong runners planted at the end of August last year I am at this date (July 9) gathering nice fruits.—G. WYTHES.

#### GOOD EARLY NECTARINES.

In answer to the courteous criticism by "Fruit Grower" on page 6, I think he has somewhat misunderstood my note on the above. I have not the issue by me in which I mentioned Early Rivers and Cardinal, but I have no recollection of ever naming Lord Napier, as it is an old favourite of mine. At the same time, I must state that with me it has proved at least ten days later than Early Rivers grown under exactly similar conditions, and one year it was nineteen days later. Again, this year, in a house started at the new year, Early Rivers came in just right for the Ascot week and realised a high price, as the fruit was ordered by a leading fruiterer some weeks beforehand. Lord Napier not being ready until after that event was over did not fetch half the price, though equally large and well finished. Both varieties were grown in the same house, proving that Early Rivers possesses an advantage in earliness. "Fruit Grower" will admit that a space of ten days or even half that time sometimes makes a very considerable difference in the value of fruit in the market, and I can assure him that when a man has to provide for a fair-sized establishment and sell produce to pay garden expenses, it means a good deal. Although I saw the group of Nectarines grown in pots, I somehow missed the basket of Cardinal and the small tree in a pot referred to by "Fruit Grower," so was not impressed by any difference there may have been between the two. What really did impress me was the statement made by Messrs. Rivers' representative that the trees staged were not started until after Christmas, and then grown in a rather cool house. I have grown many varieties of Nectarines, but could never boast of such success, and I think Early Rivers and Cardinal are the only two sorts that would accomplish the

feat under similar conditions. As to why the latter has not been sent out, is a question beyond my power to answer. I heard nothing against its character until I saw in a contemporary that it was not recommended for outside culture. If the variety is sent out I hope to give it a trial for forcing, as it apparently answers that purpose admirably. Like "Fruit Grower" I have no interest whatever in either of the varieties beyond their value for early forcing, and if I see anything likely to pay better than older varieties, I make a note of it for future benefit. While admiring "Fruit Grower" for sticking up for an old friend like Lord Napier, I must praise him for the polite way in which he does it. Just a line as to Nectarines casting their buds on our light, hot sandy soil. Hardwicke, Elruge and Dryden always cast some buds, both inside and out, in spite of every attention to the roots and the trees being kept entirely free from insect enemies, and no other reason can be given than that the soil is unsuitable.

W. G. C.

#### SUCCESSIONAL MARKET STRAWBERRIES.

WHENEVER a new Strawberry makes its appearance one of the first questions asked by many is, "Will it travel well?" as when the over-plus fruit from so many private gardens is sent to market, it matters little how good a cropper or how richly flavoured the variety may be, few care to plant it unless the first-named qualification—"firmness"—is present. The lack of this is the one great drawback with Noble. Like the old Keens' Seedling, it is too soft for sending to a distance unless packed carefully in single layers, which it will not pay the market grower to do. If the market is close at hand, then these two heavy and certain croppers may be grown and made the best of, but for consigning to a long distance by rail packed in bulk they are next to useless, the money returned from the salesman, after his commission has been deducted, being often inadequate to pay for labour, to say nothing of a margin for actual profit; and what is true of Noble and Keens' is equally so of all soft-fleshed varieties from a market point of view. Taking cropping powers, flavour, and solidity combined, I find Competitor in the front rank for first early supplies. This Strawberry is very firm and distinct in flavour, which is rich for an early sort. It is also very hardy and vigorous in growth, and, what is perhaps as important as anything, it produces fruit over a very long period. Following this, that old and well-tried variety, Vicountesse Héricart de Thury, must still rank high as an all-round profitable sort, for although the individual fruit is somewhat small, the crop which may be secured from well-managed plants is enormous. Those who are thinking of planting for market, and who have not what is termed a good Strawberry soil, should certainly include Vicountesse for very early work. Royal Sovereign will doubtless take a prominent position as a market Strawberry, but the price of runners at present proves, of course, a barrier to growers of small means. I have previously expressed the belief that Gunton Park will eventually become one of the principal main-crop Strawberries. It comes into use just when the best fruit of Royal Sovereign is over, is as large as that variety, of a much darker, richer colour, while the flavour is good enough to please even the most fastidious. As a firm, good travelling Strawberry Gunton Park is about the best I have ever handled. Another very good point in its character is the one so noticeable in its relative, Lord Sutfield, that of yielding its fruit on bold, stout stems, which do not easily fall about and

allow the fruit to rot through contact with the wet ground. Sir Joseph Paxton must still be included in the list of market Strawberries, for although there are gardens in which it refuses to fruit, as a rule it does well, the fruit firm and of good colour and flavour. On our light soil Sir Joseph Paxton is not at home, for although the plants grow freely enough, not more than two or three in a long row yield fruit. I therefore abandoned its culture, and substituted a Hertfordshire raised variety called Premier, much like it in general appearance, and a very fair cropper. President, now much grown for the London and other markets, is none too firm for travelling, and as it ripens simultaneously with Gunton Park, it will, I expect, be less and less grown as that fine variety becomes better known. Sir Charles Napier is a profitable Strawberry where it succeeds, possessing every good quality needed to make a good market sort, but unless on good land, retentive of moisture, it is often very disappointing, the plants dying off wholesale. On our light soil it will not grow at all. For following on, Lord Suffield will take a leading place in fields and market gardens generally, as its habit is good, having ample foliage to shield the bloom from late frosts. It crops enormously, and the fruit when ripe is almost as dark as that of Waterloo, the flavour is delicious, making a splendid preserve. Newton Seedling, still later, should be included in the list, being very free both in growth and cropping, and most useful for preserving. Finally, Latest of All is indispensable for prolonging the season from ten days to a fortnight after other sorts are done. The fruit is large, handsome, and of extra good flavour, well repaying good cultivation.

The above list of good market Strawberries might be lengthened, but I see no need for it, as the foregoing varieties are all and crop in rotation over the whole of the Strawberry season.

J. CRAWFORD.

**Cherry Governor Wood.**—I do not think there is a better cropper than this, and as regards quality it is difficult to beat. My note as regards its cropping qualities is as a wall tree on a favourable aspect. I have very fine trees on a west aspect and they never fail to bear freely. This variety, of American origin, is also known under the name of Dr. Kirtland, and is said to be the best bearing Cherry of its kind. It possesses several advantages over some of the Bigarreau type, as the tree does not canker or gum and succeeds indoors or out. When given a wall in a cool house it is very fine. This season I gathered the first fruits on June 15, and have continued to do so daily since. I have no knowledge of its behaviour as a bush or pyramid.—S. H. M.

**Thinning Apples.**—In many parts there are very heavy crops of Apples, and unless some of the fruit is thinned out early, the fruit will be small and of comparatively little value when ripe. On standard trees it is not an easy matter to thus thin the crop, but a large number of dwarf or low-growing trees can be gone over in a short time, and all who have had much experience in marketing Apples know the trees that have been relieved of a portion of their burden swell up the fruit that is left until it attains a large size, and realises a high price when sold. My practice for a number of years has been to go over the dwarf trees about this time and remove any fruits that are badly shaped, blemished by insects, or otherwise detached, sending them at once to market, and I find the practice pays handsomely. At the same time it is advisable to state that it pays to sort the Apples into two sizes, placing all the largest fruit in one set of hampers and the small ones in others; the former sell very well for cooking and the latter are eagerly purchased from the salesman by jam-makers, so that there need be no waste at all, for, though no fancy prices can be

expected, there is a return that more than pays for the labour and freight charges, to say nothing of the benefit received by the fruit remaining on the trees. Again, when marketing the crop there is no trouble in grading the Apples, as all the inferior ones have been taken off; in fact, it would be difficult to estimate the value of the early thinning of heavily cropped trees. In some places all the largest Apples are picked immediately they are of a good market size, the smaller ones being left on to grow large. After trying that system against the one first mentioned, I found it far from remunerative, as the small ones that had been left never attained a really good size, and somewhat low prices prevailed for the same from beginning to end. But by the method advocated, such prices are realised for the Apples when finally gathered as should convince the most sceptical that they will pay well in this country for cultivation in spite of all competition from abroad.—W. G. C.

**Fig Osborn's Prolific.**—At page 5 "J. C." notes the good qualities of this well-known Fig. He finishes his note with the remark that some of the earlier forcing Figs which have been introduced since the advent of Brown Turkey are rather small, Osborn's being the reverse and most prolific. I do not quite agree with the remarks as to the newly-introduced varieties being small, as I am inclined to think that what is lost in size is gained in quantity and in earliness as well as freedom from dropping, while they are equally, if not more prolific. For the last few years I have had some twenty varieties on trial, but do not find I have noted Osborn's as one of the best; but, of course, much depends upon the mode of culture and the season at which the fruit is required. Doubtless for dishes at this date or the end of June, Osborn's may be all one can desire, but if you require Figs in March or April I certainly would not despise the newer, though somewhat smaller, varieties. For general culture, planted out, Osborn's comes large, and is of excellent flavour, and a grand Fig for cropping at this season, but for early forcing I do not think it can be compared to White Marseilles, Pingo de Mel, or St. John's. In Mr. Barron's excellent article on Figs and their culture at Chiswick he gives but little notice to Osborn's Prolific; indeed, he classes it as synonymous with Brown Turkey. We all know how prolific the Brown Turkey is—its value for second cropping and its fine fruit when well grown—but I am inclined to think there are some distinct kinds of this variety, as I have trees in the same house quite different in every way, one being very similar to Osborn's; indeed, when the fruit is quite ripe it only appears a little rounder in shape. For early forcing I would advise "J. C." to give Pingo de Mel a trial in pots. It is a fine Fig and of splendid flavour, earlier than Osborn's, and equal in quality.—FIG GROWER.

**Currants.**—Two very fine Currants from Jersey presented to the fruit committee at the last Drill Hall meeting, one white, the other red, and under new names might very well have passed as new and distinct, were there afforded no means of comparison with other varieties. Fortunately, there were present at the meeting not only several varieties finely fruited, shown on branches by Messrs. Veitch and Sons, but further, Mr. Barron had brought up from Chiswick quite a considerable collection, covering no doubt all the varieties in cultivation, and these even showed in several cases distinctness in leafage only, the fruits being almost identical. Of the Langley varieties, Red Cherry, Fox's Large Grape, La Fertile and Victoria were the finest reds. The last is the best late variety, and a capital one for walls or bushes to net up to keep into the autumn. The whites were White Transparent, very pale; White Crystal and White Dutch. Of the Chiswick collection a few of the finest were Wallace's Seedling, Mallow-leaved, Red Grape and Red Cherry, also White Dutch and White Cut-leaved. It was easy enough to see that with these varieties there was ample likeness to the two sorts from Jersey; hence we were saved from additions to an already

too large list of Currants, as the distinctions between many are so very minute. The Mallow-leaved and the White Cut-leaved are very distinct in foliage and both carry very fine clusters of fruit, and they are varieties that well merit notice.—A. D.

#### STRAWBERRIES.

In spite of the long drought the crop has been a fairly good one where mulching was done early, with an occasional soaking of water since. At the same time some varieties have greatly excelled others both in crop and size of fruit, though grown under similar conditions on the same quarters. Royal Sovereign confirms the good opinion already expressed by many practical men, and I believe this variety will become as popular with market growers in the future as Sir Joseph Paxton has been for so many years. It was one of the first to ripen its fruit, and has continued in bearing for as long a period as any sort that I grow, the fruit being large, firm, and of excellent quality. La France has done remarkably well this trying season, being only second to Royal Sovereign in cropping, size of berry, and firmness, and equal, if not superior, in flavour. The foliage is somewhat scanty compared with that of many other varieties on our light soil; consequently the plants would suffer in a dry time unless well mulched, but treated as an annual, and done thoroughly well, it is a very fine variety. Helene Gloede, though not so richly flavoured as the preceding varieties, has run them closely in weight of crop, and appears to withstand drought better than any other sort, the foliage keeping very fresh and green, forming a good shade to the berries. Sir Joseph Paxton, Sir Charles Napier, James Veitch, La Grosse Sucrée, and Auguste Nicaiss have proved about equal in bearing, the two last named, however, surpassing the others in flavour. President set a splendid crop, which swelled to a nice size, and then the plants suddenly collapsed, and the fruit was useless. It should be stated that the plants had been mulched and given several thorough waterings. It would be interesting to know if President has behaved in a like manner in other places, as I never recollect its failing so completely in former dry seasons. Vicomtesse Héricart de Thury always succeeds admirably, and for home use is one of the most reliable varieties that I know, being as valuable for forcing as in the open air. Latest of All is, I think, one of the grandest late Strawberries in cultivation. Wet or dry seasons seem to have little effect on its constitution or bearing powers, and the size of fruit and delicious flavour make it worthy of a place in every garden. Grown as an annual the fruit is very fine and abundant; if allowed to stand more than one year on our hot soil, the berries are much smaller, and, in my opinion, suffer in flavour as compared with those from one-year-old plants. Waterloo I had to root out a few seasons ago, as my employer had a decided objection to the mulberry colour of the fruit, but where this is no detriment the variety is well worth growing. It is of no use to try to obtain full crops of Waterloo from plants one year old; for several years I tried it on that system by the side of other sorts, and found it would not succeed under two years. I had a few choice varieties sent me late in the autumn of last year, but, owing to the severe winter and present drought, I have had no opportunity of proving their merits, and it would be unfair to criticise them now, but I hope to give a few notes on them another season.

Although mulched and well watered, our plants are making scarcely any runners: if this

is general, there will be some difficulty in securing sufficient young plants to make new beds shortly, and in such cases extra attention should be given to those beds already formed, by supplying plenty of moisture not only to the roots, but overhead as well, thus enabling the plants to mature bold crowns for the future, and also warding off that enemy so common this year, viz., red spider. On all sides we hear of this mite infesting hardy fruit trees of all kinds, and, unless treated as suggested, Strawberry plants will not escape, if not already attacked. A thoroughly good washing two or three times a week with the garden engine will not only assist to keep the plants clean, but also act as a check to the enemy on fruit and other trees. W. G. C.

## ROSE GARDEN.

### ROSES AT CHESHUNT.

THE present season has not brought out any Rose of Continental origin worthy of mention so far as we have seen, but most Rose growers regard Kaiserin Augusta Victoria as a good variety. Several promising new varieties of the Hybrid Perpetual section are now flowering with Mr. G. Paul, all of his own raising and each in sufficient quantity to give a very good indication of its merits generally. T. B. Haywood is one of them and bears fine full flowers of a light crimson shade, in form resembling those of Alfred Colomb. They are sweetly scented and the growth of the plant is robust. Haileybury is also a fine Rose which received an award of merit at the last meeting of the Royal Horticultural Society. It is even stronger in growth than T. B. Haywood, has fine flowers of a most distinct shade of rose, which deepens into rosy crimson in the outer petals. Both of these are up to the exhibition standard, and may therefore be safely tried by all growers. Bacchus attracted our notice at the Palace show, where Mr. Paul had a bunch of it in a class for Roses in bunches of not less than seven trusses. It should make a very good garden Rose, being of vigorous growth, and, judging from the successional buds developing, a true perpetual bloomer. Its beauty is in the bud state, and if free it will make a gay bush or give abundance of flowers for cutting. The buds are long and pointed and of a rich velvet crimson. The colour becomes duller as the flower expands, but even with all the wealth of red Hybrid Perpetuals there is room for Bacchus, with its bold rich buds, that can be cut with long shoots. Alan Cheales is a distinct variety, with a globular flower of a soft rose colour, the inner surface of the petals a bright shade of rosy cerise, which gives a pretty glow to the centre of the flower. Paul's Early Blush, though not new, may be mentioned as one of the acquisitions of recent years, charming in its tender colour, but above all most valuable for the quality implied by its name—that of earliness. It is by a long way the earliest of light-coloured Roses, and Mr. Paul is preparing to plant a very large breadth of it solely for furnishing cut flowers, its earliness adding to its value for this purpose. We might remark here that Paul's Early Blush and Mrs. Harkness are synonymous.

A series of beds filled with some of the very best

### ROSES FOR GROUPING

was an instructive feature, as one could see their merits at a glance. Mme. Chedane Guinoisseau was beautiful, each shoot crowned with a cluster of sweet and bright yellow buds. This Rose

has been in the country now more than ten years, but not being up to show form, it has remained in comparative obscurity; yet, in common with Mme. Charles, Mme. Falcot and others, it is just the Rose to make a gay group of lasting beauty. Gustave Regis, Mme. Pierre Cochet and Mme. Pernet-Ducher are all of similar character and certain to give a pleasing effect to those who break away from the conventional plan of planting single plants and have a bold mass or group of them. Camoens, now well known, was very good, and we have its counterpart in another colour in Marquise de Salisbury, a recent addition that has been much praised and merits all that has been said in its favour. Cheshunt Scarlet is evidently one that must not be overlooked. Its flowers are brighter than those of Marquise de Salisbury, larger, borne erect in clusters and brilliant in effect. La Fraicheur also makes a pretty free-flowering group, most distinct in its shade of pink; and Augustine Guinoisseau, in pale blush, makes one of the longest flowering and certainly one of the sweetest groups of any Rose.

### MULCHING ROSES.

ON paying a second visit to Colchester on July 2 I found a further secret of the success of some of the Rose growers in the application of a surface mulch of sewage, which I have found in a long practice one of the most useful and powerful stimulants for Roses. I happened to drop in whilst the last liquid mulch of the season was being applied by Messrs. Prior and Sons to large plantations of Roses, and amongst the extremely vigorous plants and forests of advancing buds it was difficult to realise that zero frosts, scorching drought and whipping winds had prevailed on each side of these sloping banks of Roses throughout the year. Some may object to designating a sewage dressing a mulch, but I like the phrase. House and town sewage has, as a rule, sufficient solids in suspension to form a scum or deposit on the surface of the land, and if this is broken up or mixed with the soil by hoe, rake, or harrow, a surface covering or mulch of a very valuable sort is provided. Such feeding mulches as town or other sewage, however, should not be applied to Roses too late in the growing season, as such powerful stimulants continue growth and bloom too late in the year, and thus render the plants easier victims to winter or spring frosts.

Roses, however, on poor or shallow soils may be greatly benefited through their period of semi-dormancy by liberal dressings of sewage. It is important to bear in mind that Rose roots are seldom or ever at rest unless frost-bound, and likewise that there is often a serious loss of sewage in winter which might be utilised in the nourishment of the root runs of our Roses.

The other mulch in general use through the great Colchester Rose grounds is 2 inches or so of loose soil. Neither water nor sewage is available in the majority of the Rose gardens; the soil in most of these may be described as a loam leaning to heaviness rather than friability—in fine, a Rose loam. This soil, improved by liberal and deep culture and alternating crops of roots and corn, proves a sure and certain antidote to Rose sickness, and lays the foundation of success deep and strong.

Other mulches, such as those of solid manures in various stages of decomposition, straw litter, chaff, tan, cocoa fibre refuse, ashes, burnt earth, &c., are also used. But few have sufficient of these to cover acres of ground. Neither are they needful, as is proved by the present vigorous growth and crowded blossoms on the Roses around Colchester after months of parching drought. To keep the moisture in the soil and the parching heat out, gangs of men with sharp hoes are constantly among the Roses keeping down weeds, uprooting suckers, and forming a surface tilth almost invulnerable to the entrance of drought from

above or the escape of moisture from below. So soon as they get to one side of the field of Roses they return to whence they started, and so on and on whilst the drought lasts, strengthening, through hoeing, the surface mulch of earth. D. T. F.

**Rose Emperor de Maroc.**—One so seldom meets with this old Rose, that I thought it had been discarded to make room for newer kinds. In Messrs. Jackman's Woking nurseries I saw a large batch of it. The flower is very dark, probably the darkest crimson of any Rose. The flower does not grow to a large size, nor is the form up to the standard required by exhibitors, hence its scarcity, yet the plant is free-blooming and a fine Rose for the garden.—S.

**Rose Mrs. Anthony Waterer.**—This is a new Rose that has been raised by Mr. Anthony Waterer, Junr., of the Knap Hill Nursery, by crossing *Rosa rugosa* (syn., *R. ferox*) with the well-known Hybrid Perpetual General Jacqueminot. The result has been to produce a very beautiful Rose of free and graceful habit, with flowers of exceptional fragrance. The foliage, whilst quite different from that of *R. rugosa*, is suggestive more of that parent than the other. The leaves, consisting of five or seven leaflets, are firm in texture, serrated, and not so much wrinkled as in *R. rugosa*. The petioles and the branches are armed with small decurved spines, stouter and less needle-like than those of the parent species. The flowers are semi-double and of a rich crimson colour, the outside of the petals having a rosy tinge. They are, I think, equal in the sweetness and strength of their fragrance to any other Rose, and the profuse flowering character of this hybrid may be judged by the fact that this year between seventy and eighty flowers, each measuring from 3 inches to 4 inches across, have been produced on a single branch of last year's growth. In habit it is more spreading and elegant than *R. rugosa*.—W. J. B.

## GARDEN FLORA.

### PLATE 1023.

#### THE BAHAMAS MALLOW.

(WITH A COLOURED PLATE OF SPHERALCEA ABUTILOIDES.\*)

THIS plant belongs to the Mallow family which is most familiar to us in gardens by the Hollyhock and Abutilon. Although it was singled out by the artist as a plant worthy of a place among the portraits in the "Garden Flora," the plate would not give one the impression of the plant being such a beautiful one as it really is, though the elegance of a flowering spray is admirably shown. It appears to be an old garden plant, having been introduced from the Bahamas 170 years ago, and re-introduced to Kew a few years since, from whence we hope it will be again distributed to English gardens. It is a greenhouse plant, or rather should be grown in a warm greenhouse. Its chief value as a garden plant lies in the fact that it blooms in winter, when it is specially welcome. The specimen figured would lead one to suppose it to be of straggling growth, but herbarium specimens at Kew show it to be very robust. It is a wild plant with Abutilon-like leaves twice the size of those drawn, and flowers freely on stout stems. Probably it would prove more valuable for winter flowering if it were planted out during summer. Well-flowered plants of it in midwinter are unusually attractive, the deli-

cate colour being effective, as in the temperate house at Kew, while the plants last in bloom a long time.

There are many Sphæralceas, but only a few seem to be suitable as showy garden plants. In turning over the specimens at Kew I came across some very fine species, which appear to be all Mexican and South American. Besides *S. abutiloides*, the others of a similar character are *S. umbellata*, with fine heads of large flowers borne in an umbellate way and broad palmate leaves; *S. nutans*, with very large Abutilon-like flowers and also Vine-like foliage; *S. vitifolia*, with leaves like the common Vine and large showy flowers. Both *S. umbellata* and *S. nutans* are, I believe, in cultivation, and there is a fine specimen from Mr. Gumbleton, in whose garden in Ireland the plant appears to grow with native vigour. These Sphæralceas I have named are not merely of botanical interest, but really fine plants that one should be able to obtain in the best nurseries, and it ought not now-a-days to be a difficult matter to obtain seeds from their native habitats.

W. G.

## THE WEEK'S WORK.

### HARDY FRUITS.

**STRAWBERRIES.**—In spite of the drought in most parts of the kingdom, the plants, when well treated in the way of food and often renewed, have given good crops. The cultivator will now be making preparations for another season. There is considerable gain by growing young plants in such seasons as this and 1893, as being more robust, they are better able to resist drought, the soil can be more highly cultivated, and the return is much better, the fruits larger and of better quality. Another point often lost sight of is that young plants are less subject to insect pests and stronger. The soil for future crops should now be prepared by deep digging, or trenching if required. Strawberries may with advantage follow crops that have not been a long time in the soil, but even then ample supplies of food are essential, as it must be borne in mind that quick growth and large and well-matured crowns are necessary. In shallow soils it is useless to trench; deep digging will suffice, feeding from the surface afterwards. No matter what position be given, much depends upon the plants, mode of planting, and after-management. At this season it is well to take into consideration the value of new varieties. To plant these wholesale is not advisable, as it is well to see how they thrive in the soil. From most quarters a very good account is given of the new Royal Sovereign, and as far as my own experience goes I consider it a good variety for all soils where earliness, size and quality are considered. For late work the useful Latest of All is well worthy of a trial. Whatever kinds are planted it is important to get strong runners and to plant as early as possible.

**LAYERING FOR PLANTING.**—When the layers of new varieties or others are procured from a distance, it is well to get them sufficiently strong for planting. At times they are sent none too strong, and it is well to pot up such into small pots, placing under a north wall or shading for a short time. In this way no time will be lost, as if planted as received there are losses and much labour in watering. Small runners may also be planted in lines rather closely, and put out early in the spring they make fine material for another year, but should not be allowed to fruit the same season as planted. When plants are secured from home-grown stock, they should be layered as soon as possible. I do not think small pots can be beaten, although equally good results may be secured by placing some good soil in the rows between the plants and firmly pegging the strong runners into the new soil, taking away surplus growth and keeping the runners watered

daily. Another older, but still good method is to chop square pieces of turf and plunge in the alleys, layering the runners into the turf.

**PLANTING STRAWBERRIES.**—Firm planting is most important, as unless the plants are well trodden in in light land growth is not robust, and in winter the frost lifts the plants out of the earth. It is a good plan to draw drills in light soils, this allowing of watering freely. The distance between the plants depends upon the variety and the space at command. There is no gain in crowding; 2 feet is none too much between the rows, and more should be given for plants fruited more than one year, 18 inches being allowed between the plants. For such varieties as King of the Earlies, Black Prince, or Alpine these distances do not apply, 12 inches between the plants being sufficient if not left too long in one place. I only allow one crop of fruit, and requiring many runners for forcing I plant at 2½ feet apart in the row with 12 inches between the plants, planting at the end of July or early in August strong rooted runners. These soon attain a good size, and are not allowed to fruit the first season after planting. When the runners are obtained, every other plant in the row is cut out and the beds left to fruit the following season. In planting it is well to spread out the roots so that the top roots are well covered, but not to bury the leaves or the centre of the plant, and to give ample moisture in dry weather.

**EARLY STRAWBERRY BEDS.**—Those who can devote a small space on a south or raised border would do well to plant specially for early fruits. Many can devote a small space in front of fruit houses on borders with the Vine or Peach roots inside, and in such a position may gather fruits ten days in advance of the open quarters, as it is easy to protect a small plot and to thin the early fruits. A few dishes in advance are valuable and greatly prolong the Strawberry season. In late springs or cold weather such quarters may readily be covered with a few spare lights or hand-glasses. For this purpose Noble answers well; it may not be all one may desire as regards flavour, but it comes large, is of a bright colour and very early. Planting may be done at 2 feet or even less if grown for one year's fruit, and for this purpose it is not wise to fruit longer, early and large fruit being secured from young plants.

**LATE BEDS** are almost as important as very early ones. A north border is a good position for the late lot, and the heavier the soil the better. I have noted the importance of Latest of All, a new variety for late use, and which so far surpasses the Pine section, and will thrive where British Queen fails. Oxonian, Waterloo, and Elton Pine are all suitable for north borders. To these should be added Aberdeen Favourite, superior in flavour to Oxonian, and a valuable late variety. The same cultural details are necessary as advised for the earlier crop, but if possible more space should be given to allow of mulching and keeping the plants clear, the growth being more robust. For late fruit I do not advise a sloping border, as the moisture so necessary for the plants is drained away. Plenty of space is required between the rows to prevent mildew being troublesome in wet seasons and to allow the fruit to dry freely.

**RASPBERRIES.**—To prolong the crop, which in this district is a heavy one, it is well to mulch freely, using partially-decayed manure, as the latter will retain the waterings which will be required and assist the new growths at the base to grow freely. In light gravelly soils this fruit soon fails if not given moisture. It is well to reduce all suckers, as these absorb the moisture so necessary for the plants, and though a few of the best or strongest suckers will be necessary to grow on, these should now be selected, and not more than six left at each stool, finally thinning to three or four when the crop is cleared. The strong kinds, of which Superlative is one of the best, are more vigorous than older kinds, and should not be crowded. After the crop of the early kinds is cleared the old fruiting canes should be cut out, thus throwing all the vigour into next season's fruiting canes.

**AUTUMN FRUITING RASPBERRIES.**—These, where at all thick, may be thinned if very fine fruits are desired, and in some places it is necessary to tie out the canes to admit light and air. The same remarks apply as regards mulching, but of course the reverse treatment as regards sucker growth. To induce plenty of fruiting spurs from strong canes it is well to top the last-named, this causing a much better set, and in seasons of drought or in light soil a good watering with liquid manure is well repaid.

G. WYTHES.

### THE KITCHEN GARDEN.

**LATEST CELERY.**—In most places rain has now fallen, and it will be well to get out late-raised Celery. If pricked out in warm nooks and corners at the time advised and kept well watered it will now be fine stuff, not at all liable to run to seed either in late autumn or early spring. With a favourable autumn this very late batch will often grow to a respectable size, quite fit for table use and to mix in the salad bowl. If not, however, it is always useful to use for flavouring and soups, the main lots being spared for more important purposes. The trenches need not be quite so deep as usual and the plants may be rather closer to each other. When planting is completed, if a good mulch of old Mushroom manure is spread down each side of the rows and one good soaking given, it will generally take care of itself until freeing the sticks from suckers and the first earthing up are done. If the two varieties Leicester Red and Standard-bearer are grown as advised at sowing time, there will not be one in a hundred that will perish through rot, be the winter ever so wet, as sown and brought on in quite a cool temperature their constitution is so hardy.

**COLEWORTS.**—The present is the best time for making the principal sowing of the good old hardy London Colewort. Purchase the seed from some reliable house, as there are inferior strains of this vegetable which run out coarse and flavourless. I usually sow mine on a south-east border from which early Potatoes or Peas have been cleared. This I prefer to a due south one, as the young seedlings are more easily kept moist and they do not come on so rapidly. The beds are simply marked out and the seed sown broadcast, scuffling it in beneath the surface with a small rake, finally treading and levelling. I always net my Colewort beds as soon as the seed is sown, as if postponed the seed often comes up before one is aware of it, and the chaffinches get them all. My dates of sowing are the 7th of July and from the 15th to the 20th; the latter sowing often proves most serviceable if the autumn is very warm and the first batch grows away too speedily. There are still very many gardeners who do not grow Coleworts, but all should do so, as nothing equals them for hardness and flavour.

**CABBAGES.**—I am not an advocate for extra early sowings of spring Cabbage, as frequently in very mild autumns the plants grow so rapidly, that should very sharp frosts occur in December, they get such a check that they heart in at that season when the Coleworts are plentiful and preferable, and thus time and labour are lost. In large gardens, however, where ground is not an object a sowing may be made about the 10th or 12th of the month, but not of the very earliest varieties, these being more susceptible to the evil above referred to than the larger varieties, such as Enfield Market. Of course, in northern, cold districts the above date may be chosen for the main crop sowing, otherwise from the 25th to the end of the month will suit best. I make a second sowing the second week in August to follow the first batch of Ellam's, Cocoa-nut, and Earliest of All, and for putting into frames for winter protection a small sowing should be made about the 20th of August. Do not confine yourself to one or even two sorts; three or four should be grown, bolting and other failures being thus guarded against. Early Offenham, Mein's No. 1, and Early Rainham, which some think identical with Ellam's, are all capital Cabbages of very rich

flavour. Sow on the level in preference to raised beds and protect from birds. The red pickling Cabbages may be sown with the second batch of spring varieties, and a little seed also with the latest for wintering in frames.

**CUCUMBER HOUSE.**—Plants which have been bearing fruit since March will in many instances show signs of semi-exhaustion, and must be treated accordingly. If others, either in houses or in pits, are now bearing, it will be well to allow the first-named lot a partial rest. Thin out the wood freely, leaving only that which is more robust and free from spider. Give a good rich surface-dressing and feed liberally twice a week. Keep the foliage well syringed, close early, and allow no fruit to swell off for three weeks or so; if a little freedom in growth is allowed instead of close tying in it will aid the plants to grow out of their weak state, and the growths can be tied in when the plants are again allowed to bear more fruit. I have previously spoken in praise of Perpetual Bearer both as a house and frame variety, and this season my high opinion of it is strengthened. It has a grand constitution, the fruit grows rapidly and in great numbers, the quality being good. If wanted for exhibition it may be had 26 inches long, with the flower still on the end. This would make a capital Cucumber for market. In surfacing Cucumber beds always use plenty of opening material, such as mortar rubble, so as to allow of the copious waterings passing away freely. Much harm is often done to Cucumber plants that have been bearing for some time by allowing the fruit to hang on too long, thus unnecessarily robbing the plants of their vitality. The fruit should be cut as soon as ready and placed in cool quarters, the stem end being laid in damp Moss. Cucumbers that are the least aged should not be used in the salad bowl, as they impart a bitter flavour to the salad and are not wholesome.

**BLANKS IN WINTER STUFF.**—Owing to the protracted drought during June, a good many blanks have occurred in quarters of winter greens, especially Brussels Sprouts, these having taken the disease commonly known as "finger and toe." The foliage then rapidly changes from a green to a sickly bluish colour and generally becomes infested with insects. These blanks should now be made good from the seed-beds, and if the young plants are at all overgrown, take out a good sized hole and make the soil about the roots very moist; they will then go away. It is useless pulling up these extra large plants in the usual way and planting with a dibble, as thereby all the principal rootlets are ruined. Of course, where any extra late sowings of sprouts and Kale were made, the plants from these beds may be used, as with a fine autumn they will yet make good-sized stems and be extra valuable on account of yielding their sprouts later. If any healthy plants of late Broccoli, such as Late Queen, Methven's June or Model are still in the seed beds, they may be planted on a north border, if such can be spared, from which some other crop has been cleared, no further disturbance of the ground being advisable. In such positions Broccoli often stands the winter better than in more open sunny ones, growth being more gradual and less sappy, the hard root-run assisting this. J. CRAWFORD.

**Notes from Holme Lacy.**—A great feature of the place is the immense Yew hedges surrounding the flower garden. Some idea of the size and extent of these hedges may be formed when it is stated that it takes two men six weeks to trim them once. The flower garden is well protected from cold winds by the high thick hedges, and at the time of my visit (end of June) presented a gorgeous appearance, two Tropaeolums—Mrs. Clibran, a splendid yellow, and the better known Vesuvius—being very fine. Herbaceous plants are grown in two long borders backed by the Yew hedges. The drought apparently had not affected the plants in the least, as they all looked remarkably healthy: one plant of *Lilium giganteum*, with eight flowers on a spike, was particularly striking. A short distance away are the lakes, well stocked

with Water Lilies. The clear water, large green leaves and great quantity of charming white flowers produced a picture that my pen fails to do justice to. In the shrubberies the frost of last winter has made no unsightly gaps, and not a tree or bush has required cutting back. Roses also escaped injury, and the Teas in the Rose garden were covered with very fine blooms and buds. Carnations are very extensively grown in nearly all known varieties, Mrs. Reynolds-Hole, Miss Joliffe, Uriah Pike, Andrew Campbell, King Arthur, and Miss E. Terry being extra good. Sweet Peas are grown in great variety and quantity, as they are so much appreciated for room decoration: in fact, all flowers that will travel well are largely grown. In the kitchen garden the crops looked remarkably well for such a trying season. The fruit at Holme Lacy has long been famous, and is now well kept up to its past standard of excellence. Pears of all sorts are particularly fine, the well known cordons on the wall being especially good. Apples and Plums are bearing profusely; some standard trees of Blenheim Orange are bending down now with the heavy crop. Melons and Tomatoes are grown in quantity and their general condition left nothing to be desired.—W. G. C.

## KITCHEN GARDEN.

### CABBAGE FOR SPRING SUPPLIES.

THOSE who require early spring Cabbages must now make preparations. In giving advice at this season it will be necessary to take into account localities, soils and varieties. It is most difficult to draw a hard-and-fast line as to the exact date for sowing. Every grower has a certain date for sowing, but those who may have failed previously will be guided by the growth of the plants and sow accordingly. On the other hand, I do not advise undue delay, as small weak plants do not winter well. I do not rely upon one sowing. Much depends upon the variety, as a large coarse Cabbage raised too early invariably bolts, whereas such kinds as Ellam's may be sown at any date from July 10 to July 20, and will not run if there is no check in planting out or crowding in the seed bed. I need scarcely refer to the value of spring Cabbages. Few crops are more valuable, and few vegetables more appreciated after a long winter. To obtain a good breadth of Cabbage as early as possible in the spring the grower must be on the alert at this date and select a variety that will not run, and the earlier it turns in the more valuable the crop. I am writing from a private grower's point of view, as for market much larger heads may be necessary. Still, even for that purpose I fail to see the gain, as smaller kinds with compact folding leaves winter best, do not run with extremes of weather, and being planted more closely together there is a larger number, which, with earliness, makes up for size.

Ellam's Dwarf is, in my opinion, the very best for first crop, owing to its hardiness, earliness, and freedom from running. Out of many thousands this spring, after a severe winter, not one plant bolted. I commenced to cut the third week in April (a little later than usual), but taking the winter into account, not a bad record. Mein's No. 1 is also very similar, but with me Ellam's turns in first. It has the same good qualities as regards hardiness and freedom from running, and on heavy clay land, I think is superior to Ellam's, being stronger. Veitch's Matchless is another good early form, with small leaves and compact growth, somewhat like Mein's No. 1, but broader, not so conical, most desirable for autumn sowing, and of delicate flavour. The above varieties may

be relied upon in all soils and localities. Mein's No. 1 should be grown in exposed positions or in wet clayey soil. For light land Ellam's is the most reliable if well treated and sown at the proper date, with plenty of room for the plants to develop.

### SOWING

is an important detail, but, as previously stated, is ruled by the locality. I sow on July 10 and 20. The reason for two sowings is that if the plants from the former are too large, those from the second are mostly planted. Generally the first sowing is a small one; only a limited number is planted and the plants are treated differently. They are planted in deeply-dug, heavily-manured land, and in a mild season are fit to cut early in March, but if otherwise, such plants suffer severely and are little earlier than those from the chief sowing ten days later. The plants sown at the later date are planted in large quantities and mostly on hard land. Drills are drawn in the ground just cleared of the Onion crop, no digging or forking being done, and the growth is hard, sturdy, and able to resist frost. There are no losses, and though growth may not be so luxuriant in the autumn, the plants are not injured so much and start away freely as the days lengthen. It may be asked, why make two sowings if the later is so superior? But should the winter be favourable there are two strings to one's bow. Kales and Brussels Sprouts run so soon in the early spring, that the first-sown Cabbages are most valuable, and if a fortnight earlier than others, worth the little trouble. Thin sowing should be practised, and a large bed for the seeds is necessary. A flat surface in the open should be prepared, giving ample moisture before and after sowing in dry weather. I also advise sowing broadcast, well covering the seeds with soil, in light soil treading the beds before sowing to give a firm root hold. Early planting is advisable, not allowing the plants to get large. Should the ground not be ready to plant it is better to prick off into lines for a time, lifting into the permanent quarters later on, and planting with a trowel. Assistance may be given in the way of protecting the stems. My plan is to well firm the plants early in December by treading down each side of the row, afterwards moulding up well. This preserves the stem and protects from east winds, so injurious after frost. It is advantageous to feed early in the year in mild, showery weather with guano or liquid manure.

G. WYTHES.

**Late French Beans.**—It frequently happens that runner Beans are cut down by an early frost even in September, and if a few plants of a dwarf kind are grown specially for late dishes, they may be given protection. I have grown both the runner and dwarf varieties for this purpose, but the dwarfs are the best for the latest supplies. If the runners are grown they require to be topped at 15 inches from the soil and to be sown in rows, so that they may readily be covered. The new climbing French Bean is well adapted for late use if stopped, as it produces so freely and is of excellent quality. For late sowing Ne Plus Ultra and the larger Canadian Wonder are the most productive; the latter variety, if given a few sticks to support the tops, may be readily covered with canvas or mats. Many shifts can be made to have a late supply. It is not necessary to grow under walls unless frames or span-lights can be afforded to cover the crop. I find that by sowing in the open on a raised border the plants dry sooner in dull weather and frost is not so injurious. I have for years sown this crop after the first early Potatoes, and a fine return the plants give. Whatever position is afforded them the ground

should be well worked, as a good root-run is essential. If the soil is dry it is well to draw the drills and saturate the soil before sowing, also repeating the watering after the seed is covered, thinning out early, and not crowding in any way.—G. W. S.

**Pits and frames.**—These where used for growing early vegetables should now be cleared of all Pea haulm and other refuse, the soil turned up so as to admit plenty of sun and air and to receive the rains so as to be in a fit state for Endive, Lettuce, Cauliflower and other similar subjects in autumn for winter protection.—J. CRAWFORD.

#### CLUB IN CABBAGES.

Is there a fertiliser with which Cabbages, &c., might be watered two or three times a week as a preventive to the club? Do you consider that watering in the hot weather would increase the growth of the plants and be a check to this pest?—E. T. H.

\* \* \* Root disease would appear to be more prevalent than usual this season, and the blanks created among breadths of Cauliflowers, Cabbages, and such like are very annoying. Where trouble in this direction has previously been experienced, preventive measures ought always to be taken. In many instances the roots of plants in the seed beds will have commenced clubbing before they are large enough to put out. Sometimes it is caused by the grub of a small beetle or weevil, and occasionally the maggot of a midge or fly is responsible for the mischief. A free use of soot and lime, forking it into the surface of the bed before sowing the seed, has a deterrent effect, and so also has sand soaked in petroleum, the surface of the bed being dressed with this every week or ten days. Before planting examine the underground portion of stem of each plant, and cleanly cut away every small excrescence or wart there found, following this up with the old-fashioned remedy of puddling the roots of all the plants. Form a puddle with clay, soot, lime and water, a wineglassful of petroleum being also added with advantage, and drag the roots through this so as to thoroughly coat them and the lower portion of the stems with the puddle. Thus treated, they seem to feel the check of removal less than when not puddled, and are seldom interfered with by either maggots or wireworms afterwards. It is on stale, indifferently cultivated ground that grubs most often gain the ascendancy, and "E. T. H." will do well to do all he can towards promoting a vigorous growth of plants by way of prevention of club root. Newly-slaked lime at the rate of one bushel per rod ought to be forked into the surface of the previously well-manured ground, and after the plants have been put out, all being carefully fixed, clear water should be given for a time, or for the first week or so, afterwards giving liquid manure frequently. Nitrate of soda or that in mixture with superphosphate of lime, dissolved at the rate of one ounce to a gallon of water, would be the best form of fertiliser for the purpose. Apply at first round the plants, but when the latter are growing strongly draw mould up to the stems and pour the liquid manure freely along the furrows. Petroleum is one of the best insecticides ever discovered, and in extreme cases of club root I would advise soaking sand in it and mixing the latter freely with the soil in which the Cabbages are planted.—W. I.

**Defoliating Tomatoes.**—Mr. Iggulden's notes on this subject bring vividly to my mind an incident that occurred in an Essex garden some years ago. Tomato growing on open walls was more safe and profitable than now, and in the garden in question the crop on plants growing between the Peach trees on a south wall was very heavy: the foliage also was very dense, and in order to expose the fruit somewhat to the action of the sun, the gardener instructed one of his men to go over the plants and remove a leaf here and there and to shorten others. Instead of

this, however, he all but entirely defoliated the plants, to the great annoyance of the gardener. In the course of a few days a neighbouring gardener came over, and on seeing what had been done said nothing, but went home and gave orders for his plants to be similarly treated. Shortly after this the first named gardener paid him a visit, and on his expressing surprise at the way the plants were mutilated was met with the reply, "When I was in your garden a few days ago I saw yours had been similarly treated, and I thought that as you were a good gardener the practice must be right." The occurrence afforded a little amusement at the time, but it is almost needless to say that neither of the crops of Tomatoes was in the end satisfactory either in point of weight or quality. I quite agree with Mr. Iggulden that under certain circumstances a partial thinning out and shortening of leaves are necessary, but that excess in the matter does more harm than good.—J. CRAWFORD.

— I quite agree with W. Iggulden respecting the bad habit of defoliating Tomato plants; I have always considered it a barbarous method. I also quite agree as to the fault of planting too closely, which is a common error. Some three years since I had 7000 plants under glass, and although some of the foliage was shortened and the side-growths pinched off, I never allowed the plants to be cut up into scarecrows; indeed, at some places where they are planted 1 foot apart each way scarcely a leaf is to be seen.—EDW. BENNETT, *Jyne, Chertsey.*

**Tomatoes for Christmas.**—By sowing a few seeds now there is no difficulty in having a good supply and of fair quality at Christmas. A pan of seed should be sown now in a warm house, and when the seedlings are well above the soil removed to a close frame, potted off into small pots and grown near the light, potting again into 6-inch pots when large enough. Expose during the night and merely shade during the hottest parts of the day after repotting. These will make strong plants fit to place in pots two or three sizes larger by the end of August. Stand the plants on a hard bottom fully exposed and keep all lateral growths removed. Plants grown thus will set fruit all up the stem by early October. If placed in a warm house with a free circulation of air, and well fed, the fruit will soon swell and give a good supply through November and December. In sowing for this crop I have found none to equal Conference and Conqueror.—S. H. B.

**Tomatoes not setting.**—My experience is that, as a rule, the corrugated varieties of Tomatoes set better than the smooth ones. There are, however, exceptions to this rule, as in the case of Ladybird and Webb's Regina; both of these comparatively new sorts set most freely, and that, too, on the bottom clusters of bloom. Both of these Tomatoes are of medium size only, but most useful for private gardens, especially where the fruit is eaten in a raw state. Of the ribbed varieties I do not think there is a better than the old dwarf Orangehead when obtained true. Certainly there is no better cropper or better flavoured sort, but we seldom meet with it nowadays, its ungainly shape, I suppose, telling against it.—J. C.

**Marrows in the open.**—In forward localities these will now be in free growth and showing fruit. Where, however, a supply is being had from frame plants it will be advisable to case the open air plants for a little while thereby strengthening them for future work. If the plants are healthy and fairly vigorous, do not be induced to feed too liberally, as should the weather turn humid and sunless with cold nights disease will be likely to lay hold of them. The old-fashioned plan of growing Marrows on manure heaps is fast dying out, and rightly so, as the system had nothing to recommend it. A gross sappy growth often results, and if the summer is extra hot some good Marrows may be cut, but in opposite seasons a fruit here and there is the general rule, the majority of blooms fail to set at all or the fruit turns yellow in quite a young state. Younger

batches of plants must be encouraged to grow freely by plenty of root moisture and a good mulch of short litter. The longer the plants can be kept in a fruitless condition, provided they are not rampant, the better, as they will then be in good form for following the first lot and keeping up the supply until cut down by frost.—C.

#### JUNE IN SOUTH DEVON.

THE mean average temperature of the past month has been 57.8°, or 1.7° below the mean average for the last sixteen years, but exactly the same as that for the much duller month of June, 1894. On five days the thermometer on the grass fell below 40.5°, the lowest reading being 39° on the 16th and 20th, the highest reading in the screen being 78.0° on the 24th.

The rainfall for the month has amounted to .98 of an inch against 2.56 inches last year, and an average for sixteen years of 2.38, the total amount registered since January 1 reaching 11.76 inches against 14.96 inches in 1894. Sunshine, 273.5 hours, has been considerably above the average, which is 225.5 hours, and still further above that registered during the corresponding month of 1894, which amounted to but 184.3 hours, though in June, 1893, the sun shone for 293.65 hours, thus exceeding by over 20 hours the past month's record. The wind throughout the month has been light and variable, a very different state of affairs from June, 1894, which was phenomenally windy. The midsummer month is prodigal in the matter of flowers, Lilies, Irises, herbaceous perennials and annuals vieing with each other in their profusion of bloom. The first June Lily has been *L. davuricum*, the erect flowers of a clump of twenty bulbs forming a patch of orange-scarlet and following hard on the May-blooming *L. pyrenaicum*. Then came in order the slender-stemmed *L. tenuifolium*, its blooms spots of vivid red in the shaded Lily bed; *L. Martagon* with its dull purple Turk's-caps and the lovely white variety (*L. M. album*); then *L. croceum*, its strong 4-feet high flower-stems shooting up through the foliage of herbaceous Peonies; and lastly, *L. pardalinum*, one bulb of which more precocious than its fellows produced its blossoms during June. Many other Lilies are to come, the tallest, *L. giganteum*, already 9 feet in height and 10 inches in circumference of stalk at the ground level, missing by a few days being classed among the June flowerers. Irises of the Spanish and English sections planted in large clumps of decided colours have made a brilliant display. Care should be taken to procure good named varieties at the outset and to keep them separate, the effect of a group of mixed tints being patchy and unsatisfactory compared with the breadth of colour obtained if the varieties are kept distinct. Of Spanish Irises, Golden King is a fine orange; Yellow King and Canary Bird, seemingly synonymous, are good light yellows; Snow Queen the most satisfactory white that I have tried, and Celestial, a pretty light blue. Of English Irises, the common blue and the white Mont Blanc or La Grandesse, both being equally good, make a perfect contrast. Spanish Irises should have a lighter soil than is necessary for their English relatives, which do well here in heavy loam.

*I. Kämpferi*—since I was aided by "C. J.'s" note (p. 521, vol. xlvi.) to the effect that it should be grown in leaf-mould and well-rotted manure—has done grandly, the large clump flowering superbly during the past month. *Iris ochroleuca*, *I. aurea* and *I. Monnieri*, planted close to a little streamlet, opened the first blooms during the last week of June, their tall flanged leaves and flower-spikes rising through an undergrowth of *Spiraea japonica* and *S. filipendula*, both at the perfection of their feathery inflorescence. In another portion of the garden a large plant of *S. aruncus*, nearly 6 feet high, has been a mass of flower, and *S. arifolia* will be in full bloom by the end of the present week.

The double white Rockets have flowered throughout the month, and *Gladiolus Colvillei* The Bride with *G. insignis* have borne their white

and red spikes in close proximity, The Bride being a few days the earlier of the two. Masses of pure white *Antirrhinum* grouped with scarlet *Lychnis chalcidonica* have also been very effective, and, associated with low-growing subjects such as *Phacelia campanularia*, (*Ethiopia Youngii*, *Agathaea cœlestis* and *Tradescantia virginica*, which flower at a like time, save the borders from the appearance of formality that is unavoidable when the occupants are all of similar height. Here and there irregular patches of *Alstrœmerias* have mingled their delicate gradation of tints with the white of the double *Campanula persicifolia* and of the border Pinks. *Campanula grandis* and its white variety, with *C. latifolia*, light blue *Delphiniums* and white *Foxgloves* lifted their spires of bloom above the clumps of autumn-flowering perennial *Sunflowers*, herbaceous *Phloxes* and *Michaelmas Daisies*. The June sunshine hastened the display of the *Canterbury Bells* (purple, white and pink), *Coreopsis lanceolata* and scarlet *Zinnias* in the open beds; while in cool, shady spots the white *Violas*, *Forget-me-nots* and hybrid *Aquilegias* still continued to flower in scarcely diminished loveliness; and in a damp depression of the ground, close to the water's edge, *Mimulus variegatus* sent up a thicket of stems fully 2 feet high, crowned with a wealth of showy golden and blood-red blossoms. The large fringed orange blooms of *Inula glandulosa* expanded in unwonted profusion, and the creamy heads of *Thalictrum aquilegifolium*, composed of countless flowers individually inconspicuous, attracted at noon-tide an even larger host than usual of bees. The last of the herbaceous *Pœonies*—*Leonie*, a white, shading into delicate blush—has been one of the most beautiful, and the flowers of *Canna Ehmanni iridiflora*, though perhaps not possessing quite the brilliance of tint attained in the new dwarf race, added a striking note of colour but seldom met with in the garden. This *Canna*, which flowers until cut by the autumn frosts, when well grown will often reach a height of 6 feet, and produce leaves that are almost as handsome as those of the *Musas*. Over a pergola, fashioned from rough Larch poles, a white *Jasmine* has wreathed the leaves and tendrils of the Vines with which it is covered with white odorous clusters of blossom. At the base of a support by which one of the Vines is planted, an Ivy-leaved *Geranium*, *Souvenir de Charles Turner*, in a grey-green old *Lucca* oil jar, has perfected quite a quantity of large brilliant-tinted trusses that show up well against the celadon of the jar and the tender green of the climbing Vine.

Roses have been most beautiful, but very short-lived, basketfuls cut each morning, to be succeeded ere evening by another flower harvest. *Teas* and *Hybrid Teas* are the favourites here, *Viscountess Folkestone* with shell-pink, loosely folded petals being considered to bear the palm as a decorative variety, but where all are exquisite, judgment is as difficult as was that of *Paris*, and, swayed by no temptation to be unduly partial, the guerdon—"For the most beautiful"—remains unawarded. The *Austrian Copper* and yellow *Briers*, *Harrisoni* and *Persian Yellow*, when planted thickly are most effective, a hedge of the different varieties which separates the flower from the kitchen garden having been a marvellous revelation of vivid colouring. Before leaving the subject of *Roses* I must admit to having been sadly disappointed by *Crimson Rambler*. It may be effective at a distance, but to my mind it is over-rated. I am aware that in this opinion I shall, judging by the flourish of trumpets with which this *Rose* was received, be at variance with the majority, and that by my confession I lay myself open to the reproach of being a person of bad taste, but this knowledge does not shake my conviction.

The *Weigelas* and *Syringas* have blossomed well, a tall bush of the latter large-flowered *Philadelphus* 10 feet in height, with graceful sprays smothered in starry cups, and its beauty enhanced by the green background of the shrubbery at the edge of which it stood, seeming in its white array the very bride of June.

Despite the drought of the last two months, the young *Apple* trees are looking remarkably healthy and making satisfactory growth, the foliage being dark green and very free from blight and insect pests. S. W. F.

### HANDLIGHTS.

THE accompanying illustration shows a very nice handlight which was once made and perhaps put into the hands of dealers and nurserymen, but of that I cannot be sure. It was made, I believe, under Sir Joseph Paxton, for Chatsworth, and, besides Chiswick House, it is the only other place where I have seen it. The bars are extremely light for cast iron, not more than one-eighth of an inch thick anywhere, and it has features which ought to be recorded as suggestions to others interested. The most noticeable of these is a peculiar way of chamfering or sloping upwards the top of the body

A useful handlight. From a drawing by Mr. A. Dawson.

section with a corresponding internal chamfer on the lower edge of the top piece. This is repeated also on the lower edge of the body, and as a consequence it is easy to pile up these bodies two or three stories high before adding the top piece.

Suppose you wish for seed from a fine *Pink* or other plant. By having one or more of the body sections either partly glazed or without glass, then all the needful air will pass through and the flowers will be kept dry and produce seed, as I can testify.

I think for packing, two modifications would greatly improve them. In the cover I should do away with the handle and put a hole for the finger instead. This hole is always useful to let steam out; the lights can then be packed like cloches. The body portion may be advantageously divided into two opposite angles with tabs to join them. They will then pack into each other. The tabs or clips should be outside, or they will

break the glass on being nested. They ought also to be made of ordinary brass, although the rigidity of the cast iron is a help when a crack occurs, for it is yet stiff enough to stand. D.

### CHRYSANTHEMUMS.

#### SEASONABLE NOTES ON CULTURE.

THE present is a busy time amongst *Chrysanthemums*, as they are growing fast and require much attention. Plants grown with a limited number of stems, with the idea of producing large blooms, are generally looking well this season, having made, so far, vigorous growth, furnished with abundance of thick, fleshy leaves. Owing to their extra vigour, numerous side shoots are being pushed from the axils of the leaves; these should be promptly removed, as they are quite superfluous and rob the main branches of that support they ought to be storing up for developing the future blooms. Towards the end of the month some of the most difficult of varieties to manage will be showing a flower-bud at the point of growth. *Mrs. Alpheus Hardy* is one that is seldom seen in really good condition. Buds formed at the period named develop into satisfactory flowers. Instead, then, of removing the buds with the object of inducing fresh growth to be made, the shoots that cluster about the already formed buds should be pinched off to induce the buds to swell freely and well. Many varieties, like the *Queen of England* section, for example, are now forming buds. By pinching them out and restricting the number of shoots still to three on each plant, these same shoots will set flower-buds again at the end of August, the same developing into desirable blooms. With the present growth so promising, it is not necessary to give manurial stimulants at present. Clear water, with a weekly dose of soot water, will provide all that is necessary for another three weeks at least. As in all cases there may be exceptions, as, for instance, plants growing in extra small pots and that have been potted sufficiently long to have exhausted all the manurial properties of the soil, in such a case weak applications of liquid manure would be an advantage. By this means plants are kept growing sturdily and receive no check. The plants require regular attention in watering. They should be examined at least twice daily; dryness at the roots for any length of time means a loss of the lower leaves at a time when the plants can least spare them—I mean when the buds are swelling during September and the early part of October. In all cases rain or soft water is best; that coming from water companies' pipes or wells should be warmed by exposure in tubs. Syringe the plants daily during hot and dry weather in the evening and also early in the morning, when night dews are scarce, to create a humidity in the atmosphere about the plants.

The *Celery fly* (*Zephritis onopordinis*) is and has been very troublesome of late to the leaves of the plants. The maggot can easily be seen under the skin of the leaves where it secretes itself and quickly destroys the tissues, giving a serious check to the plants. Hand-picking persistently followed is the only efficacious remedy I know. Either squeeze the part of the leaf where the maggots are seen or pick them out with the point of a knife. Earwigs are beginning to be troublesome this season. The usual trap of *Broad Bean* stems or pieces of cane cut into lengths of 1 foot thrust amongst the leaves of the plants, and occasionally ex-

amed, will rid the plants of many of these pests.

Mildew, too, is making an early appearance on the lower leaves, especially where the plants have been given cold water during the recent hot and dry weather. Dust flowers of sulphur upon the parts affected at once; neglect of this may prove troublesome afterwards, as it is not easy to cleanse the plants of this parasite when once they are attacked on the underneath part of the leaves.

Plants intended for specimens should have their shoots topped for the last time to induce them to push forth additional growths until they make their natural break in September. Keep the branches secure from breakage by wind or other causes by securing the shoots loosely to stakes of a temporary character. Abundance of space between each is a desirable detail of culture. To have them standing thickly together, each robbing its neighbour of air and light, is not the way to ensure success; ample light and air ought at all times to be provided.

E. MOLYNEUX.

### CHRYSANTHEMUM NOTES.

A HOT, dry season suits the growth of the Chrysanthemum by hardening the leaves and wood, thus forming the foundation of a like solidity in the blossoms, as well as enhancing their colours. Such weather as we are now having means a large amount of routine work, like watering, which, however, must be done if success is to follow. It is found needful to examine the whole collection quite three times daily, for such thoughtless practices as giving water all round will not do in the case of the Chrysanthemum. This is a gross-feeding plant, but the growth is as likely to be crippled by soddening the earth as it is by allowing the latter to become dry. In each instance the roots suffer.

Where care and thought have been exercised the plants are looking exceedingly well, though a trifle more yellow in the leaves than in some seasons. This may perhaps be expected, as nothing in the way of liquid manures has yet been thought of. I have noted cases where the leaves have assumed a sickly yellow hue and the bottom ones have decayed, a far different matter, and caused by the too free use of fertilisers at the time of final potting. Rational modes of culture are always advisable. The idea that if an ounce of some strong concentrated manure is beneficial, double or treble the quantity must be more so, has not yet left growers of plants. Some, too, will start giving liquid manure almost before the roots have obtained a hold of the new soil, to the detriment of healthy growth. A matter that will very soon engage attention is

#### BUD TAKING,

that is, selecting the buds which are to remain on the plant. It is orthodox not to retain a bud on any of the autumn kinds during July, but those who cultivate the Chrysanthemum for large blooms cannot be guided by general rules. Individual varieties must be studied. Thus we find that W. G. Hewitt, The Queen, and a few other Japanese sorts are so late in bud-formation, that it may be advisable to select the one bloom-bud on the single stem and be satisfied with that number to a plant, and in the case of the well-known sort E. Molyneux, we have a choice of evils. The variety may be said to be handsome "when caught right." Generally it is most unsatisfactory from a late bud, and from an early one the colour is poor. But I would rather secure buds towards the end

of July and obtain blooms of the latter character than run the risk of getting flowers with one or two outer rows of petals and a large yellow eye. Sunflower, again, owes not a little of its popularity because of the gracefully drooping habit of its florets. To obtain this desirable form buds must be selected early, and even as early as the end of July I have found a better time than allowing the plants to make other growths upwards and taking the buds about five weeks later, a period which would not give a variety requiring a long time for development sufficient to bring out the proper characters. The ways of most of the older kinds, however, should now be pretty well known, and I will note a few of the more popular of recent introductions. The handsome light yellow Duchess of York is a variety that must have a long period for bud development, and should, therefore, be "taken" early. M. Panckoucke has a long drooping blossom and requires early bud selection for show purposes. L'Isere and Mme. Carnot, on the other hand, are not satisfactory from early buds. In the case of these fine white sorts the second bud from the first natural break is a good one to select. The fine white Niveum, unfortunately, has this season a habit of giving premature buds, but from early selected ones the sort does not develop pleasing blooms. Commandant Blusset should be allowed ample time to perfect its blooms. This sort, then, may be manipulated early. Louise is an early sort. Personally, I do not care for it when from late buds; its colour has a sickly look and is far more pleasing in its blush white tint obtained from early buds. Souvenir de Petite Amie is not satisfactory from late buds. Wilfred Marshall must have a long time for development, and President Borel comes best from late buds. Golden Gate, a fine late variety, is not obtainable in early autumn by forward bud selection. This, as well as Miss Dorothea Shea, comes of bad shape and faulty colour by adopting the plan. Mrs. W. H. Lees gives flowers with drooping florets, but I think the most desirable ones are had when the buds are taken early. Eda Prass is a very fine variety and the buds take an unusually long time to fully extend. Rose Wynne is the prettier, if not so huge in size, from buds formed late. R. Dean, again, is of the Mrs. Falconer Jameson type, requiring, therefore, early bud selection. Miss M. Blenkiron is of a similar habit. M. Ch. Molin should come from early crown buds, or it is small for show purposes, and a like remark applies to Mrs. E. G. Hill. It is hardly necessary to extend the list of Japanese sorts, as examples of most of the types have been given. Early formed flower-buds will in the case of most sorts give the larger flowers, and late ones the better coloured. For instance, Vivian Morel produces blooms of a dirty white from early buds to a satiny mauve from late ones, and the true character of many a sort is lost by not paying the necessary attention to this phase of Chrysanthemum culture. Varieties of American origin will generally be found to require longer for bloom development than do the sorts from France.

Incurved varieties may be dealt with more easily. The group known as the Princess family, including Mrs. Heal, Mrs. S. Coleman, Miss M. A. Haggas, Violet Tomlin, and Lucy Kendall must be dealt with in July. This time, however, is too early for all of the other well-known kinds. The new white sort, J. Agate, requires early bud formation, that is the crown bud should be taken. The same with the neat Globe d'Or. Robert Petfield, at the best uncertain, should be left somewhat late. The period likely to suit other classes of

Chrysanthemums, such as the Anemone-flowered, pompon, and single, is early September. At this time the terminal buds are prevalent, the last formed being the more sure in bringing out the true characters of the types mentioned. H. S.

### SHIPPING CHRYSANTHEMUMS.

UNDER the heading, "The Past Season," Mr. Michael Barker draws attention in the "American Chrysanthemum Annual" to a point of vast importance to all foreign raisers and growers of new Chrysanthemums. He says:—

There has been much complaint about the despatch of new varieties from America so late in the season, that nothing of value can be done with them in foreign countries until the following year. This means serious disappointment to the purchaser, and ultimately perhaps a great loss to the distributor.

No one without some knowledge of the English method of cultivation can properly estimate the importance of this complaint. Time after time when ordering plants for friends who have desired something new and novel from abroad have I impressed upon the growers the absolute necessity of despatching the plants in February or March, so that they can be treated in such a way as to bloom in proper form the following autumn, yet in a great many cases this request has been ignored, and small rooted cuttings have perhaps arrived in the month of June when the purchaser's collection is finally potted up into the flowering pots, and consists of strong growing plants that cannot be overtaken by the new-comers.

The practical result of this is that these new varieties stand no chance when autumn comes. There is such a multitude of new seedlings grown every year by English importers, that it is only those that succeed fairly well the first year that find a place at our floral meetings and at the trade displays. The late arrivals are all behind and, of course, may do well the following year, but time is valuable in these days of keen competition, and space cannot always be spared two years in succession for the same novelty. Hence the plants that are sent over late have to make way for the following season's novelties, and unless they find their way into the hands of a small private grower of considerable ability are seldom or never seen or heard of again.

It is, therefore, of the highest importance if a foreign raiser wishes his seedlings to compete on fair terms with those of other growers to make it a fixed rule that his novelties shall be propagated and ready for distribution by February or March at the latest. It would be easy to mention the names of several raisers who entirely disregard this plan. The result is that their names are but little known here and the majority of their flowers still less so.

One would think that one of the essentials in commerce would be to ascertain the peculiar needs of one's customers and provide accordingly. Without some such adherence to business principles foreign raisers must not expect to rank high in our estimation, nor should they complain that their seedlings are not so good as those of other growers when they themselves have been the cause of their flowers not having the chance of being properly tested. C. H. P.

**New Zealand seedlings.**—Most readers of THE GARDEN will remember the despatch by Mr. John Earland of some colonial-raised seedlings, which were exhibited at an early flower show of the National Chrysanthemum Society a few years ago. From a report of the Wellington Chrysanthemum show held last April I gather that the work of seedling-raising is still going on, and some novelties were staged, to which the

judges made special awards. The names of the new seedlings are not given in the report, but the principal growers appear to be Mr. S. Bolton, of Nelson, Mr. John Earland, of Wellington, Mr. McLeod, of Napier, and Mr. F. Cooper.—C. H. P.

#### CHRYSANTHEMUMS IN NEW ZEALAND.

ONE of the most enthusiastic and successful colonial Chrysanthemum societies I know of is that at Cambridge, Waikato, N.Z. At their exhibition held in April last some very fine blooms were staged in the classes for thirty-six, half Japanese and half incurved, distinct varieties, and twenty-four Japanese distinct. The winning stand in the first-named class was set up by Mr. T. Wells, the chairman of the society, and four judges from Auckland, who examined his stand in the twenty-four class, and which was also awarded first prize, declared that it was the best twenty-four they had ever seen.

It may be interesting to record the names of those which had such a high encomium passed upon them, and from the report the following is quoted:—

They were staged as follows, reading from left to right. The figures denote diameter in inches, except Mrs. B. Findlay and Eda Prass Japanese incurved, in which the depth is also given. Back row: Mrs. Bruce Findlay 7½ by 7, Golden Wedding, Vivian Morel 10½, Mrs. Langtry, Miss Dorothy Shea 12½, Mlle. Thérèse Rey, Thunberg, Mrs. E. D. Adams 12. Middle row: Eda Prass 7 by 6, Viscountess Hambleton 8, Jennie Williams, Chas. Davis, The Queen, Harry May, Lucrece, Mrs. Libbie Allen. Front row: Grandiflorum, Beauty of Exmouth, R. C. Kingston, Bryden, jun., O. P. Bassett, Miss A. Hartshorn, Fred. Dorner, Florence Davis. Of the new varieties in this stand, Mlle. Thérèse Rey unquestionably comes first, and fully maintains its English reputation of being "the finest white in existence." The Queen is an American introduction. It is very large and handsome, and is the queen of American whites. Mrs. E. D. Adams as shown was the perfection of beauty, being white, suffused pink, with very long curling florets; Miss Dorothy Shea is a true Japanese with long (fully 6 inches) broad florets of terra-cotta colour; Viscountess Hambleton is a Japanese incurved, large and handsome, silvery pink. Of the new yellows, Mrs. Libbie Allen is the best of this season. Mrs. Bruce Findlay was a mammoth ball of a pink incurved Japanese, as high as broad, and solid enough to be tossed across a room.

In several other classes the names of the flowers are given, which show that the New Zealand growers are keenly alive to the necessity of keeping pace with the times and importing all the newest and best European and American novelties as soon as it is possible to procure them.

There were forty-two classes provided for in the schedule, all of which were well filled, there being in some cases ten, twelve, and even fourteen entries. A gratifying feature of the Cambridge show is the competition for school children consisting of bouquets and floral designs. There were 381 entries in these classes alone.

CHRYSANTH.

### TREES AND SHRUBS.

#### DOUBLE-FLOWERED CHERRIES.

OF the numerous flowering trees and shrubs that adorn our gardens in spring and early summer, the double-flowered Cherry is one of the most valuable, for nothing could be more beautiful than the long snowy white wreaths with which the tree is crowded from top to bottom. There are two or three kinds, but the best is the one of which the accompanying is an illustration. The semi-double variety, although less beautiful, possesses the advantage of flowering earlier than the true double kind. No lawn ought to be without a tree of the double kind, and beautiful groups might be made by planting a selection of the double-flowered Peach and Almond, scarlet Hawthorn, Ame-

lanchier, and Chinese and other Crab trees, all of which flower in spring and have a handsome habit of growth. Mr. Spooner, of Arthur's Bridge Nurseries, Woking, writing to us in reference to the illustration, says:—

The branch of the double-flowered Cherry is from a tree of a very fine variety growing in my nursery here. It is a great improvement on the old sort, being much more free in its growth and producing finer blossoms. At the time the photo was taken (May 6) the tree was a mass of pure white. For planting in borders, &c., it would be hard to beat, as it comes into bloom very early, when there are few other plants in flower.

**Philadelphus microphyllus.**—This delightful little Mock Orange—from which the hybrid *P. Lemoinei*, described a short time ago in THE GARDEN, derives so much of its charm—is now fully in flower with us. *P. Lemoinei* is just out of bloom, and this makes an admirable succession plant to it. Of dwarf, compact habit, and having thin wiry stems, with leaves half an inch long, it differs entirely from every other species of *Philadelphus*. Its small proportions and neat shape render it well adapted to a rock garden where small shrubby plants are admitted. A bed

The double-flowering Cherry. Engraved for THE GARDEN from a photograph sent by Mr. W. Spooner, Arthur's Bridge Nurseries, Woking Station, Surrey.

of it 10 feet across and rather thickly planted is now a mass of white flowers, whose delicious Pine-apple-like perfume is perceptible many yards away. It strikes freely enough, and there is no reason that it should remain an uncommon plant, except that its good qualities are not generally known. A glance at plate 824 (THE GARDEN, September 26, 1891), which in no way exaggerates the charms of this shrub, will perhaps be the most effective way of recommending it. Of its cultivation nothing need be said, except that it flowers most freely when grown in the sunniest possible positions and planted in deep, fairly rich loam. It is a native of New Mexico.—W. J. B.

**Embothrium coccineum.**—This has flowered most profusely here this season. Its beauty is just fading. I never saw it so brilliant as this year, showing how much it enjoyed the almost tropical heat and dry season we have had. It is a pity such an ornamental tree or shrub should be so difficult to establish, and when established kept in health for any length of time. When it has reached the height of 20 feet or 25 feet it generally dies without any apparent cause.—W. OSBORNE, *Fota*.

**Spiræa Bumalda.**—As the season advances and flowering shrubs become scarcer the value of this *Spiræa* is always appreciated. Commencing to flower about the beginning of July, it keeps on blossoming (if the old flower-heads are removed)

until frosts set in. The variety sent out from the Knap Hill Nursery and called Anthony Waterer is the best of all the forms of *Bumalda*, and as it is just as easily grown and propagated as the ordinary form, it should have the preference. The flowers are borne at the ends of the branches in dense, flat corymbs, about 4 inches across, the colour in the typical variety being carmine, which in the variety *A. Waterer* deepens into a much more crimson shade with nearly all the purple eliminated. Both this and the type produce variegated leaves—a whole branch sometimes having all its leaves white—even if struck from the greenest shoots, so the so-called var. *variegata* sometimes offered for sale may be passed over. *S. Bumalda* is a native of Japan, and belongs to the japonica set, to which also the plants known as *callosa* and *ruberrima* belong. All of them are of neat, dwarf habit and thrive in any fairly rich soil.—B.

**Pterocarya caucasica.**—In answer to the query on page 448 as to whether the above tree is growing in the immediate neighbourhood of water I must reply most decidedly in the negative. It has always seemed strange that this particular specimen (probably the largest in England) should flourish in so wonderful a manner high and dry in our light soil when, as Mr. Wythes says, its native habitat is in the moist valleys that are

found between the Caucasian range. A friend who visited me the other day said he had seen the tree frequently in France, but individual specimens were not more than half the size of this tree. It wants cutting back some 10 feet or 12 feet on three sides out of four, but I cannot as yet muster up courage to touch it with knife or saw.—E. BURRELL.

**Genista virgata.**—This is one of the finest Brooms in cultivation, and it is somewhat singular if it be a native of Madeira that it should be so little injured by the severe weather experienced during the early part of the present year. My reason for suggesting any doubt as to its native country is that there have been so many conflicting accounts of this particular Broom, that one additional error may easily creep in. At Kew it was grown for many years under the name of *Genista elata*, but it is now changed to *G. virgata*. Then, referring to the "Dictionary of Gardening," matters are still further complicated, for there *G. virgata* is said to reach a height of 3 feet to 4 feet, while at the time that work was compiled the large bushes at Kew would be in some cases at least nearly 12 feet high. Clearly two separate plants are here intended. It should be easy to prove if this *Genista* is really a native of Madeira, for the manner in which it passed through the last winter raises a certain amount of doubt, more especially

when the conflicting character of its nomenclature is taken into consideration.—H. P.

**Spiræa arifolia.**—This beautiful shrubby Spiræa is now lovely. A tall bush covered with white panicles of bloom, some with the minute flowers fully expanded hanging in downy plumes, some on the point of opening their blossoms, is charming. An isolated position should, if possible, be chosen for this Spiræa, that its graceful form may be seen to the best advantage. Too often it is relegated to the shrubbery, where, though it exists, it is shorn of half its beauty. It is not particular as to soil, but grows to the greatest size and perfection in damp situations. It is easily propagated by division of the roots, and when once established increases in size rapidly.—S. W. F.

**Erica ciliaris alba.**—The plant referred to by "E." under the above name in THE GARDEN of June 29 (p. 458) must surely be wrongly named, and I should imagine it either a white variety of *E. cinerea* or *E. tetralix*. *Erica ciliaris* is a late flowering and very handsome hardy Heath, by no means common in gardens, and, so far as I am aware, there is no white variety of it in cultivation, although a white form would be a most desirable plant. The fact that the plant alluded to was in profuse bloom points to its being something else, as *E. ciliaris* if in flower at all would not have many blooms out so early.—H.

**Azalea occidentalis.**—The chief value of this species consists in its flowering later than the ordinary Ghent Azaleas, thus lengthening the Azalea season by several weeks. Compared with some of the best of the earlier flowering sorts—whose tints, however, can scarcely be rivalled among outdoor shrubs either in softness or brilliancy—it cannot be described as showy. The flowers are, nevertheless, produced abundantly and in good-sized trusses; each bloom about 2 inches in diameter and, with the exception of a pale yellow blotch on one petal, pure white. Their sweet fragrance adds not a little to their charm. The species has already been taken in hand by Mr. Anthony Waterer, of Knap Hill, with a view to the production of a race of Azaleas which shall at once extend the season of these shrubs and possess some of the delightful colouring of the earlier flowering varieties. Judging by the specimens he has already exhibited, we may confidently expect a large measure of success.—B.

## STOVE AND GREENHOUSE.

### TILLANDSIA DURATI.

THIS *Tillandsia* (one of the finest, if not the finest, of the southern Bromeliads) is one of the few species of the genus which have sweet-scented flowers. Nearly all the plants of this family are scentless. In tropical regions the only species, perhaps, which is known to have scented flowers is *Tillandsia fragrans*. This species, which has fragrant white flowers, I have collected in Ecuador, where it is found growing at an altitude of 2500 metres. On the other hand, some of the species found in La Plata, such as *Tillandsia Durati*, *T. xiphoides*, &c., have deliciously scented flowers, and it would appear as if the perfume was a kind of compensation bestowed upon those species which cannot boast of handsome foliage, striking stature, or brilliant bracts and flowers. These poorer forms of a family which in Brazil, on the Andes, in the Antilles, and in Mexico is so richly endowed by Nature, nevertheless present special attractions. In the first place, wherever they are found growing they are generally very abundant. *Tillandsia* (*Anoplophytum*) *stricta*, *T. microxiphion* and allied forms cover the branches of trees to their smallest twigs, and the effect of their diminutive rosettes of reddish and olive-green leaves

is enhanced by the brilliant setting-off of their bright pink bracts and blue flowers. *T. xiphoides* and *T. Arequitæ* carpet the rocks with their foliage and pretty white flowers, while *T. xiphioides* and *T. crocata* are covered with flower-spikes of a fine yellow colour.

Frequently, also, their felt-grey or nearly white leaves, looking like a strip of cloth, are twisted like a cork-screw or like the main-spring of a watch, and, although less attractive, perhaps, in appearance, the numerous slender stems of *T. usneoides*, hanging like sails from the branches of trees, and the multitudinous dense tufts of *T. recurvata* impart to the landscape an element of picturesqueness of the highest order, the ashy-grey tint of their foliage serving to bring this out more effectively by contrast with the surrounding verdure.

With respect to their culture, for a long time every importation of these "Flowers of the Air" (*flores del aire*, as they are termed in La Plata) was a failure. Most of the plants scarcely grew at all, and those that did hardly ever flowered a second time. At the present day, by following a very simple mode of treatment, one may have these plants in bloom almost every year. All that is necessary is to fasten the plant with iron wire to a piece of wood or cork without any soil or Moss, and during winter to hang it up to the glass (near the ventilator) of a temperate house. In May the plants are to be brought out of doors and hung upon the branches of trees in the full sun. During the whole summer up to October (when they are to be brought back to the house) they require no watering. Having formed some aerial roots and also young shoots in the moist atmosphere of the house prior to their removal into the open air, the growth of the rosettes of leaves takes place under the friendly influence of the sun, whose warmest beams these plants never find insupportable.

In this way year after year I treat that part of my collection which includes *Tillandsia Arequitæ*, *T. xiphoides*, *T. Unca*, *T. Myosura*, *T. dianthoidea*, *T. stricta*, and *T. microxiphion*, the plants after they are taken back to the house coming into flower in the course of the winter, and continuing to bloom until spring. During the summer it is rather a curious sight to see the pieces of wood covered with rosettes of leaves, without any appearance of roots, suspended from the branches of *Hibiscus syriacus* growing in a flower-pot, the suspended plants receiving no water except what comes from the skies.

*Tillandsia Durati*, which flowered with me last year at Lacroix, is a native of Uruguay and the Argentine Republic. Found by the English botanist Tweedie in the same localities on the Salto, Uruguay, from which I brought it away with me in the year 1890, it had been previously found in Brazil by Auguste de Sainte-Hilaire, in Bolivia by Weddell, and in Southern Peru by C. Gay, Miers, and others. The species, however, is rather rare even in the wild state. The plant forms a more or less dense tuft of stems, which are sometimes short, but may be elongated, prostrate, or twisted. The leaves are linear-lanceolate, from 10 inches to 14 inches long, and are covered on both sides with small whitish scales. Flower-stem erect and rigid and from 1 foot to over 2 feet in height. Flowers of a pale mauve-violet colour with a white centre, and produced in longish panicles; they commence to bloom at the bottom of the panicle, and continue in a fresh and unfaded condition for several days, giving out a very pleasant penetrating odour, which suggests a combination of the scents of Stocks, Primroses, and Jasmine.

When the tufts are of pretty large dimensions (like one which I brought away with me in 1890, and which measured 2 feet 4 inches in diameter, with a dozen flowering stems), the plant becomes very ornamental, and when suspended in a plant-house presents an appearance which is both novel and attractive. The whole secret of getting it to bloom well is by treating it as I have described above.—ED. ANDRE, in *Revue Horticole*.

**Nerines** (*F. L.*).—These should now be kept dry at the root, and until the flower spikes or growths appear. When the flower-spikes appear give water more freely. The Guernsey Lily proper (*N. sarniensis*) is about the first to come into flower, being followed by *N. Fothergilli* and its major variety.

**Calla Elliottiana.**—This we saw at Chelsea recently carrying fine rich yellow flowers, and strong crowns give them in succession in the same way as the old white kind, some of the plants having seed nearly ripe from early blooms and fine fresh flowers as well. The rich yellow colour is very showy and the leaves are prettily mottled with white. No doubt it will become popular when plentiful.

**Streptocarpi.**—A very good illustration of the long-flowering character of these is furnished by a batch we saw at Chelsea the other day. The plants were those that made such a fine display at the Temple show, and yet when we saw them they were still flowering as freely as in May, while crowds of buds were still to open. Having regard to the wide range of colour they now embrace, it is scarcely necessary to give them distinctive names and awards of merit, as has been done of late.

**Gesnera longiflora.**—In the spring of 1888 a coloured plate of this very distinct *Gesnera* was given in THE GARDEN, at which time, though an old plant, it was but little known, and even now its merits are not sufficiently recognised, as it possesses many desirable qualities. It is an erect growing plant, reaching a height of a yard or more, the stem and branches being clothed with a kind of rusty tomentum. The greyish tinted ovate leaves are also hairy. The flowers, which are borne on the upper part of the stem, have a long narrow tube and a widely expanded mouth. They are of a pure white tint and agreeably scented. It is a native of New Grenada and succeeds best with intermediate house treatment. For grouping and similar purposes it is extremely useful, as the long slender stems often serve to break up any undue formality. It is a plant of easy culture, succeeding, like most of its class, in a rather light open soil, and while growing it is greatly benefited by occasional doses of liquid manure.—H. P.

**Oxalis Bowieana.**—Among the many members of this extensive and variable genus, one of the best—regarded from an ornamental point of view—is *Oxalis Bowieana*, which has the largest flowers of any of the stemless forms. It is a free-growing kind, with large trifoliate leaves and blossoms, each about 1½ inches in diameter. They are borne in loose umbels on a stem that reaches a height of 6 inches to 8 inches. The colour of the blossoms is an exceptionally bright rose-red. When grown in pots, or planted at the edge of a stage to form a margin thereto, as is done at Kew, this *Oxalis*, and, in fact, several other members of the genus, are very beautiful, as their loose style of growth just fits them for such a position. This species is a native of South Africa, and was introduced therefrom in 1824. The pretty little Chilean *Oxalis lobata*, with golden yellow flowers about the size of a shilling, only reaches a height of 4 inches or so, but it forms quite a mass of its brightly coloured blooms. A distinct species that, if treated as a greenhouse plant makes a goodly show during the spring months is *Oxalis cernua*, a tuberous-rooted kind, with trifoliate leaves and beautiful clear yellow flowers, each about three-quarters of an inch across. They are borne in a many-flowered umbel on a stout stalk that

reaches a height of from 6 inches to 8 inches or thereabouts. This is a native of the Cape of Good Hope, from whence it was introduced about the middle of the last century, but it is very rarely met with.—H. P.

## BOOKS.

### A VAGABOND IN SPAIN.\*

THIS is the record of a journey or foot from Burgos to Gibraltar, via Biarritz, Pamplona, Zaragoza, Valencia, Madrid, Toledo, Seville, Granada, and the Alhambra, &c. The object of M. Luffmann's journey, as set forth in his passport, was to obtain an insight into the conditions and methods of agriculture in the Iberian Peninsula in the parts traversed by him, for the purpose of giving an account of the same in a book or pamphlet. This being so, it is surprising and somewhat disappointing that only the most passing reference is made to agricultural matters in the entire three hundred and odd pages of which the book is composed. The author's impressions of the economic value of Spain are easily summed up—a poor country and a poor people. He says: "Ours is a struggle for existence," sadly observed an intelligent native in conversation with M. Luffmann; "we can never hope to advance. 'Our internal growth,' as you call it, is in proportion to our national resources, and what are they? Here for ages we have carried on the most intense system of cultivation, and we have exercised rigid economy. We have had few endemical disasters. Yet with all this we are just where we were centuries ago."

M. Luffmann went as a tramp (he did not act the character), and if he sometimes had a tramp's welcome, he found the natives, generally speaking, hospitable and kindly. "No one can complain of the Spaniard's lack of friendliness," he says, "if once they take to you. There is a peculiar hardness in the character of many Spaniards, but take them all round I believe them as humane as any other men." The Basque women impressed him favourably. If he has little to say about agriculture, he tells us a good deal about the churches—"the commonest objects in Spain, and yet not common." His remarks on this head, however, are like those of the average Briton who has been bred in the shadow of Exeter Hall. Thus, of the cathedral of Toledo he says it contains thousands of beautiful things, "but the collection is marred by the presence of incongruous and ridiculous gimeracks, just as if it were a museum or a bric-a-brac shop. But in spite of faults of taste and flippancy of style, which are somewhat frequent, the book is not at all dull reading. One feels, however, that it is superficial. The Spanish knife, it seems, is a "bogey." The Spaniard is not quarrelsome, but he excels in the use of expletives. A bluff old colonel of engineers told the author frankly he knew nothing about Spain. "It is easy for you travelling penny-a-liners," he went on, "to say what we are and what we are not, but to what end and purpose do you prattle and complain? Let us be fair. We ask you for nothing. Do not rob us of what we have now—the greatest thing in the world." "What is that?" M. Luffmann asked. "Peace," answered the colonel. "We," the author goes on, "agreed that Spain was not worth fighting for, and that, being hard bound by natural conditions, she could never advance and keep pace with the rest of the world. Then, having pacified the old warrior by the adoption of all his opinions, I bade him good-night and went off to the Teatro Verano. I did not enjoy the performance, for the actors could neither play nor sing; but a Spanish crowd is always entertaining." In Ciudad-Real he met a reverend canon who "loved the English on account of the riches they have given to his library." This must

\* "A Vagabond in Spain." By C. Bogue Luffmann. John Murray, Albemarle Street.

have been a different stamp of ecclesiastic from the one whose library Gil Blas became the fortunate legatee of, as "Shakespeare, Milton, Bacon, and Ben Jonson were his intimate friends." He delighted also in Bulwer, Dickens, and Thackeray, and considered the Brontë sisters and George Eliot the greatest women of genius in the history of the world. But his idol, M. Luffmann adds, is Byron. After this who shall say that the Spanish clergy limit their reading to dusty theological tracts. It is laughable to think of a dignitary of the English establishment discussing books with a professional tramp. But Spain is still in many respects the country Le Sage described it. There are, it appears, 600 priests in Cordoba. Nevertheless, "Cordoba is bankrupt, nothing less; but it tries to keep its head up and indulge in light loves. It pays for big toros and keeps scores of cafés and gaming houses going, and the patrons of these resorts claim to be highly respectable and very much alive," and so on in the same strain the whole book. We could wish M. Luffmann had shown less of the tramp and more of the traveller in his pages. People with a taste for light literature will not be disappointed with "A Vagabond in Spain."

### A HAND-BOOK TO THE GAME BIRDS.\*

THIS is another of the useful series edited by Dr. Bowdler-Sharpe, and known as "Allen's Naturalist's Library," and in some respects the most interesting. Mr. Ogilvie-Grant's work in connection with the zoological department of the British Museum and his own wide reputation as an authority on game birds are guarantees of scientific accuracy. The author's aim has been to provide a useful hand-book for sportsmen in all parts of the world. The style of the book is clear and concise without sacrificing anything which gives breadth and local colour to descriptions of the birds in their native habitats. These descriptions are vivid and picturesque, and the personal experiences of men in search of game among the mountains of India, Thibet, of North America, Mexico and Borneo are pleasant to read. Among the sportsmen and naturalists who have contributed their experiences we note the names of Mr. A. O. Hume, C.B., author of the "Game Birds of India," of Captain Bendire, who wrote a "Life History of North American Birds," Mr. W. T. Blandford, Mr. J. G. Millais, Col. Legge, author of the "Birds of Ceylon," as well as of authorities like Heuglin, Abbé David, Baldwin, Wilson and others.

The present volume includes the sand grouse, willow grouse, ptarmigan, capercaillies, Canadian grouse, sharp-winged grouse, American capercaillies, pinnated grouse, other kinds of grouse (red-legged and others), snow cocks, quails (painted and others), the francolin, the tree partridges, the spur fowl, the stone, bamboo, blood, horned, Moonal, fireback, eared, wattled, Kalig and Kohlass pheasants.

### GARDENING A LA MODE.†

THIS little manual with its ridiculous title is intended for the use of amateurs, and gives the results of the author's own experiences. "When we came to live in the country," she says in the preface, "we were such cockneys, we knew absolutely nothing about gardening." In the present day, when so many people are alive to the improved use of garden vegetables, it was a good idea to include in a manual of this kind the best ways of cooking them. But, unfortunately,

\* "A Hand-Book to the Game Birds." By W. R. Ogilvie-Grant. Vol. I. W. H. Allen and Co., Ltd., 13, Waterloo Place, S.W.

† "Gardening à la Mode." (Vegetables.) By Mrs. de Salis. Longmans, Green and Co.

it is very imperfectly carried out in the present instance. Thus, to take one example, the Belgian way of cooking Brussels Sprouts is omitted, and the Brussels Sprouts which are mentioned as "the best" are the coarse English kinds, crossed with Cabbages and having nothing to do with the true Brussels Sprouts. Again, there is only one recipe given for cooking so important a vegetable as the Cauliflower. In the chapter on the cultivation of Mushrooms, the following passage (p. 67) relating to a patent system of cultivation by M. J. Nepp, of Leipsic, occurs: "*His beds are artificially prepared in such a way that indirect pulsation and aspiration are provided, and the growth stimulated by the chemical bed and the regulation of the temperature.*" This is one of the most absurd statements we have ever seen in a book.

However, as the book is not intended to be more than a manual for amateurs, it may answer its purpose well enough, so far as amateur cultivation of vegetables goes, provided they will take care to observe the motto of the book, which is *experientia docet*.

## SOCIETIES AND EXHIBITIONS.

### THE LONDON PANSY AND VIOLET SOCIETY.

EVERYBODY interested in these useful and popular flowers agreed that the exhibition held at the Crystal Palace on the 6th inst. was a very satisfactory and attractive one. It had been thought the dry weather would have affected it and that there would be but few flowers, but there were many. The northern growers came up bringing their superb fancy Pansies grown in the cool, and moister districts of Lancashire and Scotland, and the Violas in sprays were very numerous and extremely pretty. A considerable space of staging at the foot of the orchestra was quite filled.

In the open division there was but one collection of Pansies and Violas, but it was very fine and quite a show in itself. It came from Mr. S. Pye, Garstang, Preston, and consisted of twelve boards of fancy Pansies, each containing twenty-four blooms, and four large panels of Violas, each containing forty sprays. To Mr. Pye's great credit, be it stated, all the flowers were named. It was most deservedly awarded the gold medal of the society. The names of the leading varieties composing this fine exhibit will be found set forth in the following classes.

There were five exhibitors of forty-eight fancy Pansies, and here Mr. J. Sutherland, Lenzie, N.B., took the first prize with some finely developed blooms. Chief among them were Col. J. S. Stirling, Mrs. W. Watson, Miss Stirling, Maggie McPhail, Jas. Irvine, Miss Patterson, Tamworth Yellow, Mrs. Fleming, Mrs. Sherrard, Marmion, Geo. Stewart, W. H. Clark, Bernard Doulton, Mrs. M. Cuthbertson, Dr. G. McKay, Jessie Russell, Celtic Gem, Jenny Lawson, and Princess May. If any reader of THE GARDEN wishes to have a choice selection he will find it in the foregoing. Mr. M. Campbell, Blantyre, was second, and Mr. John Smellie, Busby, N.B., third. With twenty-four varieties, Mr. A. Lister, Rothesay, was first. A few of his very finest varieties will be found in Col. R. G. Buchanan, B. Doulton, Tamworth Yellow, Edward Kellett, Miss Stirling, Mrs. W. Watson, William Watson, David Russell, and Mrs. D. Johnstone. Mr. J. Smellie was second, and Messrs. Paul and Co., Bridge of Weir, third. With twelve varieties, Mr. John Smellie took the first prize and Mr. J. Lister the second. Twelve fancy Pansies in one variety is always an interesting class, and here Mr. J. Sutherland was first with Marmion, a soft pinkish-tinted flower that is very attractive. Col. R. G. Buchanan and George Stewart, both very fine varieties, were also shown. The class for unnamed seedlings is one which may be left out of the schedule.

## NOTES OF THE WEEK.

In the amateurs' division there was a good competition. In the class for twelve fancy Pansies, Mr. J. McFarlane, Glasgow, was first, his leading varieties being Maggie McPhail, Annie Knowles, Mrs. D. Johnstone, and Mrs. W. Watson. Mr. Thomas Naden, Alveston, took the second prize. With six blooms, these exhibitors occupied similar positions. With twelve of one variety Mr. Naden came first with fine blooms of Tamworth Yellow, and Mr. McFarlane came next with Maggie McPhail.

The Violas were delightful, and the method of showing them in sprays on plush or velvet-covered stands seems to show them off to the very best advantage. As a matter of course not a few of the most attractive of the exhibition varieties may be useless for the flower garden, and that is one of the main reasons why it is desirable there should be a thorough trial of the leading Violas to test their value for bedding.

With twenty-four sprays Mr. J. Smellie came first with a charming lot, chief among them being Border Witch, Craigie, Mrs. C. F. Gordon, H. A. Stewart, Beautiful Snow, Lucy Ashton and Mrs. Hay. Messrs. J. Cheal and Sons, Crawley, were second, they having, as distinct from the foregoing, beautiful sprays of William Niel, Countess of Wharnclyffe, Duchess of Fife, Lord Elcho and Countess of Kintore. With twelve sprays Messrs. Paul and Co. were first, having Iona, pale blue and black, very novel; Edina and Lemon Queen, as distinct from those already named, Messrs. J. Cheal and Son being second. With six sprays of rayless varieties Mr. A. J. Rowberry, South Woodford, came to the front; he had charming illustrations of A. J. Rowberry, a fine new yellow; Blush Queen, Christiania, Border Witch, Vestal and Blue Gown, a good half dozen in this section, the same exhibitor being first with six sprays of the miniature section, having Marginata, Violetta, Emily, Olivetta and two seedlings. There were other classes for Violas among the amateurs, in which there was generally a good competition.

The best fancy Pansy in the open classes was George Stewart, and the best spray of Viola Florizel. The best fancy Pansy in the amateurs' division was Mrs. D. Johnstone, and the best spray of Viola, Christiania.

Messrs. Dobbie and Co., of Rothesay, sent a very large group, comprising show, fancy, and tufted varieties, including all the newest and best known kinds. They were a fresh and charming lot considering the unfavourable weather we have had for these flowers.

**Royal Horticultural Society.**—The next meeting of the R.H.S. will be held on Tuesday, July 23, in the Drill Hall, James Street, Victoria Street, London. At 3 o'clock a paper by Mr. P. Brotherston on "The Carnation in Scotland" will be read.

**National Carnation and Picotee Society** (Southern Section).—I beg leave to remind your readers that the eighteenth annual exhibition of the above society will be held at the Crystal Palace on Wednesday, the 24th inst. Upwards of £150 are offered in prizes. Amongst special prizes may be mentioned the Martin R. Smith prizes for border Carnations, the flowers "to be cut from plants which have been wintered without protection in the open border, and staged without dressing exactly as they are cut from the plants." The Turner Memorial trustees give a very handsome silver cup, value £5, for the best stand of Carnations, bizarres and flakes, distinct, and twelve Picotees, distinct (amateurs only). Another special prize—not in the schedule of prizes—will be given by M. Ernest Benary, of Erfurt, Germany. The Ernest Benary memorial prize—a large silver-gilt medal—is given by the firm in memory of the late much-regretted founder of the firm (M. Ernest Benary) for the most meritorious exhibit, either of plants or cut flowers, by an amateur.—J. DOUGLAS, *Hon. Sec.*

**Cytisus capitata** is a pretty and late flowering species, of which handsome bushes are now in bloom in the University Park at Oxford. It bears its flowers, which are yellow, tipped with bronze, in a clustered head at the top of the shoots. The growth is decidedly erect and profusely clothed with trifoliate hairy leaves.

**Tropical Water Lilies** are well grown by Mr. Baker at the Oxford Botanic Garden, and at the present time they are very beautiful. The forms of *N. Lotus* are very good, and the new *N. Sturtevantii* does well here. It flowered last year. *Sagittaria montevidensis* is represented by a great mass luxuriant in leaf growth, and flowering freely as well.

**Campanula pumila.**—This little tufted Harebell is a popular plant about Banbury, and we were pleased to see masses of it in gardens on the outskirts of the town. In one place it was a special feature, forming a broad edging about a foot wide to a long narrow border extending from the road to the house. It made a perfect edging of pale blue.

**Michauxia campanuloides.**—This fine biennial is worthy of more attention by those who have deep warm soils that suit it. We have lately seen some noble specimens that reminded us of its stately character and noble beauty. Some of the finest were nearly 8 feet high, much branched, and clothed with lovely flowers from bottom to top.

**The scarlet-berried Elder.**—This beautiful sub-alpine shrub has berried freely in my garden this year. As it has a bad habit of seldom doing so in these islands, I should like to hear whether any of your readers have observed the same thing. One would like to know whether the drought and heat have any effect that can be directly traced. I had no berries in 1893.—J. C. L., *Kent.*

—This is one of the most brilliant berry-bearing shrubs we have, but, unfortunately, not often seen in gardens. At Eynsham Hall, near Oxford, it is now magnificent, several large bushes being laden with berries, which hang in thick clusters all along the shoots, weighing them down in a graceful arching manner. The situation is partially shaded and perhaps favourable, but we have never seen this shrub finer.

**Oxfordshire wild flowers.**—With all the country round parched and bare the beauty of the water flowers is doubly welcome. The streams that intersect the meadows in Oxfordshire are now in many places very gay with a tangled, but lovely mass of flowering Rush, Arrowhead, Water Plantain, giant Buttercups, Loosestrife and Meadowsweet rising out of carpets of Forget-me not and white Bedstraw.

**Campanula carpatica Robert Parker.**—This fine white-flowered dwarf Bellflower deserves to be better known. Mr. G. Paul says it was the last plant that he received from the late Mr. Robert Parker, whose name it fittingly commemorates. Although *Campanula carpatica* is easily raised from seed and gives much variety in this way, a form so fine as this, with its large expanded bells, is not likely to occur very frequently.

**Clematis Davidiana** has now established its reputation as a hardy species, and it is one of the sweetest and most beautiful of the herbaceous kinds. At Broxbourne it is already in bloom, and the plants, though quite in open quarters, are as strong and healthy as in previous years. Although it does not make a mass of bright colour, its clusters of flowers are very pretty, last a long time, coming in succession for many weeks, and their scent is delightful.

**Rubus odoratus** is a fine-flowering species to associate with the Rocky Mountain and Nootka Brambles. It most resembles the latter in habit of growth and broad, handsome leafage. We

noticed a fine group of it flowering in the Botanic Gardens at Oxford, the flowers of a deeper shade of rose-purple than usual, although this may have been the result of the shaded position in which the plants were growing. As the name implies, the flowers have a delightful scent.

**Physoategia virginica alba.**—A pure white form of *Physoategia virginica* we saw at Cheshunt is a good hardy flower that many should grow. The type itself is very pretty, lasts long in flower, and is most useful for cutting, and this white variety should be even more valuable. The large open-mouthed flowers are thickly disposed on a long spike, which grows nearly 1 yard high. The type itself is in cultivation under a number of names.

**Verbascum Blattaria**, a pretty Mullein not often seen, is at present in flower in the Oxford Botanic Garden. At a casual glance one might mistake it for *V. phoeniceum*, to which it bears a striking resemblance, especially in its delicate blush and pale tinted forms. The yellow-flowered variety, however, is especially distinct and charming, and serves to distinguish it from *V. phoeniceum*, as we do not get this colour in that variable species.

**Spiræa flagelliformis.**—A bush of this *Spiræa* 6 feet through, growing on a bank, has been a fine sight during the latter part of June, the long curving shoots, which give it its name, simply smothered from end to end with rosettes of white Hawthorn-like flowers, having a very unique effect. Though not possessing the graceful beauty of *S. arifolia* and *S. Lindleyana*, it is when of large size a very striking shrub, which is less grown than its merits deserve.—S. W. F.

**Lathyrus latifolius.**—The common Everlasting Pea is a familiar garden flower, but we never before saw it so picturesque as it is at Broughton, in Oxfordshire, where beside the village school and on a high bank a number of plants are growing in a perfectly natural way. They creep over the ground, which is hidden beneath mounds of blossom, whilst here and there a few shoots have climbed into shrubs near at hand. The picture is a delightful one and suggestive to all who have gardens.

**Eryngium amethystinum.**—Sea Hollies are lovers of the sun, and the present season must have been very congenial to them. A large break of this kind we lately saw in Messrs. Paul and Son's nursery at Broxbourne was very fine, and we have rarely seen it so fine in colour. A charming feature might be made by planting a group of this in association with the silvery white *E. giganteum*. The picture would only be for one season, as unfortunately this latter kind perishes after flowering.

**Eryngium Oliverianum.**—This Sea Holly is at the present time a valuable plant in the herbaceous border, possessing as it does a colour almost unique in the flower world. Its light electric blue shows out in striking contrast to the green foliage of the Phloxes and the many-tinted flowers of the *Alstremerias* by which it is growing. As a subject for indoor decoration it is much in request, a few sprays rising out of a bowl of Love-in-a-mist (*Nigella*) forming an extremely attractive combination. *E. Oliverianum* is sometimes confounded with *E. amethystinum*, but the latter is dwarfer growing and much less vigorous.—S. W. F.

**Cypripedium Andronicum** (*C. Rothschildianum* × *C. superbiens*).—This hybrid was raised in the nursery at St. Albans. The flowers are remarkably bold and richly coloured. To a certain extent they appear intermediate between those of the two parents, but the petals are as large as in *Morgania*, of a rich olive-green, spotted with chocolate. The dorsal sepal is a decided improvement on that of *C. Rothschildianum*, the bright chocolate lines being much more intense on an olive-green ground shading into white. The pouch is of a very dark, almost black chocolate, shading into a clear claret purple. This fine cross, which appears to possess a vigorous con-

stitution, is now in bloom in The Woodlands collection at Streatham.

**Cypripedium Princess Mary** (*C. callosum* × *C. Sanderianum*) is another beautiful addition to the *Cypripedium* hybrids, in shape resembling a fine *C. Morganii* and surpassing the very best forms of even that grand hybrid in colour. The dorsal sepal has the rich chocolate lines of *C. Rothschildianum*, but rendered still more vivid by the influence of *C. Sanderianum*; in fact, the colours throughout the whole flower are wonderfully dark and rich. The splendid purplish red pouch is very prominent, while the *Morganii*-like petals add a peculiar charm to this handsome cross. It was raised by Messrs. Sander and Co., and is now in flower in the collection of Mr. R. H. Measures, The Woodlands, Streatham.

**Flowers from Winchmore Hill.**—I am sending you a flower of *Geum Heldreichii*; it is not so good as the first blooms. *Hedysarum multijugum* is covered with flowers and is really very pretty. *Haplocarpa Leichtlinii* has stood the winter well and has been flowering all the summer, now almost over. *H. scaposa* is showing bloom. I have also sent you flowers of *Linaria repens alba*, which is very pretty in a house. *Prunella Webbiana*, a small spike from cuttings, is also a very pretty plant and remarkably free. The following Lilies are also in bloom in the open: *Brownii*, *Colchesteri*, *Lowi*, *canadense rubrum*, *Humboldtii*, *Parryi*, *Krameri*, *Van Houttei* (*Thunbergianum*), *Wallichianum* and *Washingtonianum*.—AMOS PERRY.

**Notes from Chester.**—The *Spiræas* are in splendid condition and are conspicuous about the borders and shrubberies everywhere. *Spiræa Bumalda ruberrima* has, as you see, bright pink flowers that are very pretty and showy. *S. ariæfolia*, popular—we had almost written common—as it is, deserves even a wider field of admirers, for it could scarcely be surpassed for beauty. Its dense heads of creamy plumes wave about in the summer wind, and when the glare of the day is past the distant effect of these masses of subdued colour is charming in the extreme. *Cytisus capitatus* is a distinct type, and amongst the *Veronicas* few are prettier than *Blue Gem*, a sprig of which we send on to you. This particular variety is a great favourite in nearly all the gardens of our sea-coast towns in North Wales. It thrives splendidly, flowers freely, and is constantly bright and full of bloom amid the dingy surroundings of sea sand and shrubs struggling against the adverse circumstances and improper selection which may often enough rightly describe the seaside garden.—DICKSONS.

**New Delphiniums.**—Few classes of plants have come to the front more rapidly than the Delphiniums. Some twenty years since Messrs. Kelway and Son, of Langport, Somerset, collected from every source all the varieties in commerce and commenced fertilising them with the view of working up some new varieties. Many of these have been exhibited at the metropolitan and other shows during the past ten years. In 1885 they observed amongst a large quantity of seedlings a single sulphur-coloured variety; this was fertilised with its own pollen and seed was produced. Some hundreds of seedlings were raised from this batch; two only came of a sulphur colour, the others being of various shades of blue and purple. The best of these, *Princess of Wales* (flowers of which we have received), was retained, and from seed of this variety others were raised. No. 2 (*Beauty of Langport*) was exhibited at the Royal Horticultural Society's meeting, June 11 this year, and was awarded a certificate of merit. All the sulphur-coloured kinds come true from cuttings, but from seed they invariably revert to the purple varieties. These sulphur-coloured varieties grow from 2 feet to 3 feet high, are of a very hardy, robust habit, with shining foliage, much resembling that of *Aconitum japonicum*, and very different from that of the purple varieties of *Delphinium grandiflorum*.

**Water Lilies.**—No flowers are more lovely, and the question is often asked, "How can I grow

such charming flowers?" In parks, on large estates and pleasure grounds, lakes and ponds abound that could be judiciously converted into a water garden, producing a grand effect in the landscape. With so many colours, ranging from the purest white through various shades of pink, crimson, sulphur to chrome-yellow, beautiful effects can be had on lake or pond. Here on the lake (where ice reigned supreme for two months) we have now a lovely picture, the following varieties being in bloom: *Nymphaea alba candidissima*, the large variety of the native Water Lily, flowers 6 inches in diameter, pure white, with broad petals, the earliest of all, and continuing till late; *N. Marliacea alba*, the best of hardy white Lilies, flowers large, dazzling white and fragrant, a vigorous grower, with fine bold foliage; *N. Marliacea Chromatella*, a grand variety, a vigorous grower, the foliage in a young state mottled with brown; its fragrant flowers fully as large as those of the common *N. alba*, with broad, waxy petals of a beautiful canary colour, and bright orange stamens; *N. odorata rosea*, splendid flowers, cup-shaped, of a lovely pink colour, with delicious fragrance. *N. rosea* and *N. Laydekeri rosea*, together with *N. Laydekeri lilacea*, are all so much alike in the distance that one is inclined to say they are one and the same, nevertheless they are all grand additions; the flowers on opening are a delicate pink, assuming a deep rose the second and third day. *N. Marliacea rosea* is one of the choicest of hardy pink Lilies, flowers cup-shaped, very freely produced, colour richest pink, the plant vigorous, with dark-coloured foliage. *N. Marliacea carnea*, a superb variety, very robust and free-flowering, has large flowers of a flesh colour, each 8 inches in diameter, and standing well out of the water. The whole of the above are now in full bloom, edged with large clumps of the yellow Nuphar. The effect in the noonday sun is very fine.—M. J.

## OBITUARY.

### THE LATE MR. JOHN WILLS.

MR. WILLS, to whose death we briefly referred in our last issue, was born at Chard, Somerset, in 1832. He first went into the gardens of Cricket St. Thomas, Chard, the seat of Viscount Bridport. As far as particulars can be gleaned of his early life, he went from here to St. John's Wood, London, as gardener to a Mr. Woodcock; later he was at work under Sir Joseph Paxton at the Crystal Palace and at the Pine-apple Nurseries of Messrs. A. Henderson and Son at Maida Vale. Subsequently he was gardener to Sir Edward Bowring, of Clapham Park; to Mr. Kennard, of Harrow Weald; for a time in the South Kensington Gardens of the Royal Horticultural Society, under Mr. George Eyles; and thence to Oulton Park, Tarporley, Cheshire, as head gardener to Sir Philip de Grey-Egerton, Bart., where he remained five years. While at Oulton Park he raised several fine new varieties of bicolor Pelargoniums, such as *Her Majesty*, *Beauty of Calderdale*, *Beauty of Oulton*, *Beauty of Ribblesdale*, *Gaiety*, *Golden Queen*, &c., which were put into commerce by Mr. William Bull, together with such tricolor-leaved varieties as *Florence*, *Lizzie*, and *Unique*. It was while at Oulton Park that Mr. Wills brought into such prominence the value of *Viola cornuta* as a bedding plant. After leaving Oulton Park he went as head gardener to Capt. Le G. N. Starkie, Huntroyde Park, Burnley, where he raised *Willis* and *Willis rosea* Ivy-leaved Pelargoniums, &c. Leaving here he came to London in 1870, and established himself in business as a nurseryman and floral decorator at Sussex Place, Old Brompton, and later on at Onslow Crescent, acquiring plant nurseries at Fulham and Anerley.

As a floral decorator Mr. Wills became widely known, and his work was always characterised by great originality and high-class execution. He

carried out extensive decorations at Buckingham Palace, Marlborough House, the Government offices, the Mansion House, and several private residences with a boldness that gained him high praise. On the opening of the Royal Aquarium at Westminster as a summer and winter garden he designed and planted the same, maintaining it for a considerable period and carrying out a series of important exhibitions. On the occasion of the visit of the Prince and Princess of Wales to Sheffield many years ago he decorated the Midland Railway Station and the Queen's Hotel in a very elaborate manner; he also organised a large flower show at Sandown Park, and in the seventies superintended some extensive alterations at the Royal Palace at Laeken for the King of the Belgians. When the botanical congress was held in 1866 in connection with the International Horticultural Exhibition of London in that year he contributed a paper on "The Sporting of Pelargoniums and Other Plants," which was published in the Report of Proceedings. He also published papers on the "Origin of Variegated Pelargoniums" and kindred subjects. He leaves a widow, who carries on the business at Onslow Crescent in conjunction with Mr. S. M. Segar. By his death the Royal Gardeners' Orphan Fund loses an able member of the committee and a generous supporter.

**The weather in West Herts.**—During the past week the weather has been somewhat cooler and less forcing to vegetation; in fact, on four days the highest shade temperatures were below the average for the time of year. The ground temperatures still remain high, but not quite so high as in the previous week. At 1 foot deep the reading is at the present time 3° above the July mean for that depth and 6° higher than on the same date last year. On the 11th inst. nearly two-tenths of an inch of rain fell, but a few hours afterwards the ground was as dry as ever. It is now seven weeks since any rain-water at all has come through the 2½ feet of soil in either of the percolation gauges.—E. M., *Berkhamsted*.

**Insects on Dahlias.**—Herewith I send you living specimens of an insect wholly unknown to me which two or three days ago made its appearance on some Dahlias, Celery, Asters, &c., and I enclose a few affected leaves for your inspection. I should like to know its name and the best means of getting rid of it. I am informed that last year, previous to my taking charge here, the insects affected Melons in a like manner, rendering them quite useless.—E. J. C.

\* \* The insects you sent are small weevils belonging to the genus *Apion*. The members of this genus feed on the leaves of various plants. Many of them might be shaken into a bowl of water, or the plants might be syringed with 3 lbs. of soft soap, the extract from 4 lbs. of quassia chips and 50 gallons of water, or some other good insecticide.—G. S. S.

**Insects on Vanda cœrulea.**—I have found the enclosed insects to-day on a plant of *Vanda cœrulea*; I also send a piece of leaf eaten by something. I have not been able to find any other insects on the *Vanda*. If you can give me any information respecting them through THE GARDEN I should feel greatly obliged. The *Vanda* is one of a batch imported last February.—G. H. B.

\* \* The insects you found on your *Vanda cœrulea* were specimens of an exotic plant bug. They were in an immature condition, consequently it is difficult to name them. The injuries were, I expect, caused by these insects. Should you find any more a little later on and would kindly send them to the office, I should probably be able to name them. By all means destroy all you can find.—G. S. S.

**Names of plants.**—E. Pidsley.—Not equal to many forms now in cultivation.

No. 1236. SATURDAY, July 27, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## FLOWER GARDEN.

### LILIES AT OAKWOOD.

In a rather elevated position and well exposed *L. Krameri* has bloomed very well, but although the plants are healthy and the flowers perfect there is a vast difference in the appearance of those growing in another part of the garden, and which are in the enjoyment of totally opposite conditions. These latter are in a very sheltered place, where but little sun can reach them and cold winds cannot directly influence them. The foliage is as rich in colour as that of *L. speciosum*, one stem carrying six blooms and running up to a height of 5 feet. It is not often that one sees this lovely Lily in thoroughly good condition, and it very seldom attains such vigour as at Oakwood. In a general way the flower-stems produce from one to three flowers only. It is one of the loveliest of the Lilies, and the pity is that the conditions, necessary to secure perennial vigour cannot easily be secured in gardens generally. *L. Browni* is another Lily that one does not often meet with doing well in the open ground. It appears to be well established at Oakwood, throwing up stout stems several feet high, with healthy deep green foliage, and looking very different from the specimens that one sees sometimes grown in pots, and which give no idea of the true vigour of this beautiful Lily. I was much impressed with the fine appearance of a group of *L. pardalinum*, consisting of about 100 bulbs. The growth is vigorous, the plants being well set with buds and clothed almost to the soil with ample, deep green leaves. The appearance of this Lily under such conditions is remarkably pleasing. I am of opinion that *L. pardalinum* should get more attention than is now the case from growers of hardy flowers. From the fact that the above-mentioned group is on high ground in a rather exposed position and not a leaf shows sign of distress from heat and drought, I should imagine that it is not so hard to please as most of the finer forms of the family. It ought to do in any garden where the soil is good and a fair amount of shelter can be had. In any case I would advise all who love Lilies to try a bulb or two. Another Lily that much resembles the above in the fresh rich green of the foliage is *L. Humboldtii*. It is evidently quite at home at Oakwood. A group of seedling forms of *Szovitzianum* had thrown up tall stems among the branches of a low-growing Apple tree. The flowers exhibited some little diversity in colour. This seems to be a free-growing Lily that ought to succeed under fair garden culture, but it is difficult to draw definite conclusions with respect to Lilies in this matter. With them the unexpected often happens, and just where one might expect them to do well, they not unfrequently refuse to thrive and sometimes die out. I have known both *auratum* and *speciosum* to act in this way in beds of carefully prepared soil whilst doing splendidly in an adjacent garden in ordinary ground that vegetables had been grown in for generations. Mr. Wilson's practice has been to distribute each Lily as much as possible, and it is in this way that success in the case of any particular species is most likely to be attained. It is then easy to compare re-

sults and form an idea of its needs. A bulb planted at random may find the conditions necessary to its welfare and which might be wanting in other parts of the garden.

J. C. B.

### LATHYRUS MAGELLANICUS.

As I am quite as anxious as your correspondent "D." to discover and obtain a plant of the beautiful blue Pea known to botanists under the above-mentioned name and also as Lord Anson's Pea, I sincerely hope that the eminent and well-known introducer of new and interesting plants who writes from Ipswich in answer to "D.'s" question in your last issue may be mistaken as to this most lovely of perennial Peas being lost to cultivation and that we may yet one day see it brightening our walls and herbaceous borders. Besides the portrait cited in the answer to your correspondent's question, it is also figured in a much more satisfactory manner by Sweet on plate 344 of the fourth volume of the second series of his "British Flower Garden," and a well-known northern plantsman assures me that for many years he grew a Pea identical with that figured by Sweet, and distributed scores of plants of it to various customers, but has now run out of it. In Mrs. Loudon's "Lady's Flower Garden" the name of *L. Armitageanus* is given as a synonym for *L. magellanicus*, and as I have recently received from a correspondent in Scotland a plant of a Pea under this name which I believe he originally received from the Yorkshire nurseryman above mentioned, I am not without hopes that this when it blooms (which I fear it will not be strong enough to do this year) may turn out to be the perennial sky-blue Pea which I am so anxious to possess. On the other hand, a plant is figured in Maund's "Botanic Garden," vol. 6, plate 526, under the name of *L. Armitageanus* which is said to approach nearer to *magellanicus* than any other that has been described, and to differ from it only in the stipules being narrower, and not broader, than the leaflets. It is said also to be perfectly hardy and almost evergreen. Again in that beautifully illustrated and exceedingly seldom-met-with work, Knowles and Westcott's "Floral Cabinet," vol. 3, plate 110, I find another good figure of *Lathyrus Armitageanus* which in the accompanying letterpress is said to be a native of Brazil, and consequently only half hardy in Great Britain, but easily propagated by cuttings, as it but seldom ripens seed. It was introduced into the Birmingham Botanic Garden in 1834. It seems to me, after carefully comparing all these above cited coloured plates, that the flowers of *L. magellanicus* as figured by Mrs. Loudon and Sweet are decidedly of a more beautiful shade of cerulean blue than those of *L. Armitageanus* as figured by Maund and Knowles and Westcott, the flowers of the latter variety being of a distinctly purplish hue and also rather smaller. There is also a conflict of testimony between two of these authorities, as Maund says *L. magellanicus* is an annual, whereas Mrs. Loudon says it is a perennial plant. W. E. GUMBLETON.

**Campanula persicifolia.**—Backhouse's form of *C. p. alba grandiflora* is up to the present time a decided improvement upon all others, but Mr. Ladhams, by carefully hybridising and selecting the best forms, has obtained a plant more robust than the type itself.—E. M.

**Delphinium grandiflorum.**—I see a note (p. 12) on this plant which induces me to ask whether the writer of it or any other of your readers can tell us anything about it. It is a plant greatly to be desired, but I have never been able to keep it through a winter in the open myself, nor have I ever known anybody who could, nor have I ever seen an established plant in a private or nursery garden. On the other hand, it is undeniable that the principal nurserymen who deal in these sorts of things continue to offer it at a price varying from about 2s. 6d. to 3s. 6d. or 5s., though it never seems to get cheaper. It is clear, therefore, that it must be grown (and to some extent multiplied)

somewhere, and what I want to know is whether this is done in these islands (in warm light soils, for instance), or whether they manage these things better in France, or whether the heathen Chinese has it up his sleeve along with the rest of his tricks that are vain. The single *D. sinense* is itself little more than a biennial, but then this is raised from seed with the utmost ease, which, of course, does not apply to the double variety.—J. C. L.

**Viola Christiania.**—A spray of this variety obtained the award for the best, selected from the whole exhibition, at the late Pansy show. It is a nicely formed flower of the faintest lemon-coloured white, with a conspicuous orange spot in the centre. Something may be said of the lasting qualities of the blooms in a cut state. I saw the above spray one day after the show and it was comparatively fresh. The flowers were cut the night before the exhibition, and from that time to the time I saw them they had been severed from the plant forty-eight hours, besides bearing the heat of the Crystal Palace. The plant has a tufted habit of growth and is free flowering.—H.

### FLOWER GARDEN NOTES.

**FAILURES.**—Each year in connection with the summer bedding it is advisable to note any failures that may occur, so that if necessary one can find substitutes for those plants that have not been satisfactory. Of course one has to make allowances for special seasons; it would hardly be fair, for instance, to condemn anything on trial for the first time if it failed in a season like the present, especially if there has been no chance of watering. Concerning those plants which in the majority of places were once prominent favourites, but which are now seldom seen, it is fortunate that efficient substitutes have been found for them nearly what is required in the matter of colour, and immeasurably superior in adapting themselves fairly well to all soils and situations. Thoroughly good strains of *Phlox Drummondii* and *Petunias* for *Verbenas* and *Marigolds*, *Violas* and yellow *Tropæolum* for *Calceolarias*, are cases in point. So far as *Verbenas* are concerned, it is somewhat strange that whilst in a few places they still do remarkably well, in others it is practically impossible to do anything with them. I remember a place where they were bedded in thousands, and were the finest feature in the flower garden until a disease in the shape of a kind of black mildew made its appearance, and after a couple of years the culture of *Verbenas* was reluctantly abandoned. It seized on the tips of young shoots, and although it yielded to dustings with flowers of sulphur, the growth was checked, and new growth so soon as it appeared was again attacked if the applications of sulphur were not followed up. It was before either *Phlox Drummondii* or *Petunias* were represented by such fine bedding strains, and efficient substitutes for the *Verbenas* were rather hard to find. I fancy the decline of *Verbenas* gave the first strong incentive to the cultivation of tufted *Pansies* so far as the summer flower garden is concerned. Still more common than the failure of *Verbenas* is that of bedding *Calceolarias*; few gardeners attempt the cultivation of these miffy subjects, and a thoroughly good display is very seldom seen. I have sometimes been fairly successful with them by taking out a good portion of the natural soil and working in leaf soil and moist red sand in the proportion of three to one, but such a compost would have to be practically flooded every second or third day in a season like the present if the plants were to do any good. Yellow *Antirrhinums* and *Calendula Orange King* are the best fairly large substitutes for *Calceolarias*, but to have the *Marigold* last out the season, decaying flowers must be promptly removed, and the plants get plenty of water if the weather is hot and dry. Tufted *Pansies* *Bullion*, *Sovereign* and *Lord Elcho*, and Mrs. Chibran *Tropæolum* are good dwarf yellows. In the lighter shades there is no plant makes a more beautiful bed than the prim-

rose-coloured Chrysanthemum or Paris Daisy, if one can keep the maggot from the foliage. This is imperative, as the plants when bored all over by this objectionable insect have a very rubbishy appearance. I can do very little with *Begonia Worthiana*, and shall be glad to know if any readers have a similar experience. Both in 1893 and 1894, two directly opposite seasons from a climatic stand point, it failed to give satisfaction, and I have therefore been obliged to discard it reluctantly because where it does well it makes a very handsome bed, and if planted thinly on a dwarf carpet, individual plants grow to a large size.

**HARDY FLOWERS.**—This is the first time since planting *Alstroemerias* twelve years ago that I have to chronicle a failure. The growth is only about half the usual height and flower-spikes are few and far between. *Hemerocallis* in variety are plentiful, but although somewhat similar in colour, they lack the delicate beauty of the *Alstroemerias*. Possibly there are few more beautiful hardy plants just at present than the red and white forms of Everlasting Pea. I saw them to perfection the other day in a cottage garden, very large clumps growing on either side of a path and forming a delightful arch overhead. Both varieties might be planted largely more frequently than they are in nearly all places where hardy flowers are extensively used; they possess the merit of standing well in a cut state, and the white variety is especially valuable. They have the reputation of moving badly, but, in common with many other hardy plants, it is more a question of well-prepared ground, careful lifting and re-planting, a good surface mulching and, if necessary, one thorough soaking of water. Very vigorous growth or a great profusion of flower must not be expected the first season, but if a sturdy healthy vine that keeps the foliage well is secured, the ultimate success of the shifting is undoubted. Nearly the same remarks are applicable to all herbaceous plants which, although all the better if not disturbed when once established, may yet be moved with impunity if the operation is carefully performed.

**ANNUALS.**—Owing to the comparative failure of several families of herbaceous plants there is rather a dearth of flowers for cutting, except from the Carnation beds, and the value of good batches of these annuals that stand well in water, as *Godetias*, *Cornflowers*, *Stocks*, *Malope* and *Sweet Peas*, is thereby considerably enhanced. It seems rather strange to advocate the mulching of beds of annuals, but where they have been sown mainly to secure cut flowers such treatment will be found advisable, if not imperative, if a long sustained season is required. The best things we have at present are *Sweet Peas*, the two varieties of *Malope*, *Iceland Poppies* and the small-flowered single *Helianthus*, and last, although not least, the varieties of *Sweet Sultan*. Where the ground was not thoroughly well done the annuals are a decided failure, the prolonged drought having brought them to a premature end. Plants raised somewhat late for autumn cutting, as *Scabious*, or for autumn transplanting, as *Wallflowers*, had to receive special treatment. The borders had a good dressing of manure, and were dug up deeply, they received a slight treading to settle them down, and, drills being drawn, a good soaking of water was given an hour or two before the seed was sown.

Claremont.

E. BURRELL.

***Hemerocallis Kwanso foliis variegatis.***—This handsome Day Lily is now in bloom. Its flowers are very similar in colour to those of *H. fulva*, the petals being of rather greater consistency and oftentimes striped with a lighter tint. Its chief beauty, however, lies undeniably in its foliage, which is beautifully variegated in longitudinal stripes. One clump that I have possesses leaves almost perfectly white, lined with thin stripes of green. In another clump the colours alternate in equal proportions, while in a third the green predominates. By some this plant is recommended for greenhouse culture, it being judged by them to be of doubtful hardiness. Though

specimens are undoubtedly extremely decorative in the conservatory, my experience points to *H. Kwanso* f. v. being equally hardy with *H. fulva* and *H. flava*, my plants having withstood 22° of frost and the late protracted winter alike without injury, and having grown in size and beauty year by year. It is a plant which is, unfortunately, but little known in gardens, but, owing to its extended season of attractiveness, there are few occupants of the herbaceous border that surpass it in value.—S. W. F.

#### ALSTROEMERIAS FROM SEED.

I HAVE raised plants of a white *Alstroemeria* from seed for the greenhouse, and wish to know whether the plants should be plunged in fibre like bulbs. The pots are at present standing in the open.—INQUIRER.

\* \* \* "Inquirer" would have materially assisted us in our desire to furnish information by stating the age of the plants and also the variety grown. The many species and forms of this beautiful genus are as varied in their requirements as they are in hardiness and time of flowering. In the absence of precise information, however, we may reasonably assume that the white *Alstroemeria* referred to is *A. pelegrina alba* (the Lily of the Incas), probably the most chaste and beautiful of this useful group. It is, however, a tender kind, and must always be grown secure from frost, preferably in a cool greenhouse. Seedlings of this charming plant require very liberal treatment in their earlier stages, and if sown thickly in pots or pans should be transplanted as soon as large enough, four in a 5-inch pot or five in a 6-inch pot being quite enough to permit of the full development of the tubers. The soil best suited is loam, peat, leaf soil, together with some well rotted manure, about one-sixth, and a little sharp sand. The plants should be grown on till they exhibit signs of decay naturally, at which time water should be gradually withheld. When the growths are fully ripened off, the pots containing them may be plunged in ashes or cocoa-nut fibre in the open. With young seedling plants extremes of dryness should be avoided, and therefore sufficient water must be given to keep the tubers comparatively plump. Plunged in the open in their pots, water once a week will be sufficient to secure this condition. If the seedlings have been transplanted several in a pot, as suggested above, it will be best to transfer them to 8-inch or 9-inch pots, with as little disturbance as possible when re-starting into growth. But should the young plants be in any way crowded in their present pots, the best results will be secured by shaking them out early in the ensuing autumn, replanting the largest tubers five or six into pots 8 inches or 9 inches across. The soil above named will suit them well, affording a fair amount of drainage, and when in full growth liberal supplies of water at the root. A little clear soot water twice a week will give colour to the foliage.—E. J.

#### DISEASE IN LILIUM CANDIDUM.

Now that the flowering season of the *Madonna Lily* has arrived it may be well to draw attention to the disease which has decimated its ranks for the last few years. A careful perusal of vols. 45 and 46 of *THE GARDEN* can but lead one to the conclusion that, widespread though the destruction seems to have been, no definite opinion as to the cause of the visitation has as yet been arrived at.

I find that fourteen notes on this subject are contained in the two volumes mentioned, and that the causes assigned for the epidemic are almost as numerous. One writer ascribes it to the heavy rainfall and the sodden state of the earth, another points out that the disease appears in dry as well as during wet summers, a third puts it down to poverty of soil, a fourth to injury of the foliage by storms, while a fifth disproves this contention by quoting the fact that bulbs grown entirely under glass are likewise liable to

failure from the same cause. My own theory is, that the disease is mostly, if not entirely, confined to imported bulbs.

I gave (vol. 46, p. 123) an account of a row of one hundred bulbs that had succumbed, whilst a bulb that came from a cottager's garden and which was growing not 3 yards distant from the affected imported bulbs showed no sign of disease. This year the single bulb has thrown up three stems, each about 4 feet high which are blooming grandly, while the hundred that after their failure were relegated to the kitchen garden have produced but one flowering spike, the remainder of their foliage being much spotted by disease and some of the foot-high stems rotten, as are many of the bulbs which I have just examined. In the cottager gardens around, *L. candidum* flourishes in perfection and has apparently done so for ages. Even in years when disease has been rife among the French bulbs I have never seen a sign of it on the cottagers' Lilies, which appear to grow with equal vigour in light and in heavy soil, in dry and damp situations, in the sun and in the shade. The other day I came across a *Madonna Lily* 5 feet 8 inches high with a head consisting of thirty-one flowers, the finest specimen that I had ever seen. In a neighbouring nursery out of a large plot of imported bulbs not a single flowering stem has been produced, and another garden that I know of where similar bulbs were procured has fared equally badly. The conclusion that is forced upon me is that had we trusted to home-grown bulbs, the disease would never have appeared. I shall be glad to elicit the opinions of others on this subject, as I hope that if we can but fathom the cause, we may be able to stamp out the plague spot that works such havoc in our Lily beds.

S. W. F.

#### EVERLASTING PEAS.

I SHALL be glad to be informed why it is that in some districts the common Everlasting Pea (*Lathyrus latifolius*) comes so much larger and deeper in colour than in others. I cannot think that it shows any real distinctness, because I have seen in old farmhouse gardens in Kent very fine forms of it, and on bringing rooted plants to the neighbourhood of London have found them to assume an inferior form. I have also raised many seedlings from a fine type only to find not one reproduce the fine parental character. Cases have been known where an unusually fine development has occurred, but the progeny has rarely, if ever, developed unusual quality. When at Boston a few days ago I saw growing against the entrance to Burton Hall, the residence of Mr. Alfred Johnson, a huge bush, the flowers large in size and brilliant in colour, unlike what one can find in the neighbourhood of London, but which can yet be met with in various parts of the country, the colouring superb, the size and substance remarkable. I seem forced to the conclusion that it is very much a question of cultivation, and that some property in the soil governs this striking fineness of development.

At Ealing I cannot induce the white form of *L. latifolius* to grow with anything like satisfaction. I have made the ground specially for it, mulched it, watered it in dry weather, and then only to find it fail. But the variety known as *delicatus*, the bluish flowers delicately tinted and striped with pink, does remarkably well, and blooms with great freedom. It is a beautiful variety, an excellent companion to the purple and white forms. The difficulty of getting seeds saved from the white variety to produce white flowering types is well known, as so many of the plants bear purple flowers. In the case of *delicatus* the proportion of plants true to the type is a good one. With me the last named appears to bloom much more freely than the common form. The larger dwarf-growing perennial Pea, commonly known as *L. grandiflorus*—its flowers of great size, the colours purple, crimson and rose—appears to do well anywhere when once established and let alone. It is the earliest of the perennial Peas to

bloom, and very rarely produces seeds, though I have known a very few put in an appearance in the course of a hot, dry summer, and in such a season as this some seeds may be discovered. Next in order of blooming is the form of *L. rotundifolius*, grown under the name of *L. Drummondii*. This is the name under which I received it from Mr. Charles Green. There is enough difference between the two to justify its being classed as a variety, and I find it comes quite true from seed. It is a vigorous grower and blooms most profusely, the flowers of a lively salmon-carmine tint. A well-established plant of it forms a dense bush. I find all these perennial Peas are greatly helped by a mulching of good manure in early spring, and during dry weather they will take full supplies of water. If thus liberally treated, clumps will stand for years and be objects of great beauty if carefully staked and the branches kept firmly tied to them.

Previous to sowing seeds of Everlasting Peas it is well to soak them in water for a few hours, especially so if the seeds are a year or so old. This is a wrinkle I learned from Mr. Charles Green. I allow the seeds to soak in the water for eight or ten hours, and then four or five hours after I take them out, sow them, and they soon germinate. I sow in pots and pot off as soon as large enough. R. D.

**Sweet-scented Verbena hardy.**—In the autumn of 1894 I plunged a number of stools of Chrysanthemums of various kinds in their pots when flowering was completed. The whole of the plants occupied a position against the wall of a greenhouse, where they would receive considerable protection. Coal ashes was the material used, and with this the stools were covered quite 3 inches deep. But quite by accident a plant of the above Verbena, which must have been standing near, was included with the Chrysanthemums, receiving the same covering. It was no surprise that the excessive and long-continued frost early this year was sufficient to kill the Chrysanthemums, and having abundance in reserve, I did not hesitate to discard them. In doing this the plant of Verbena was discovered just breaking into growth quite freely. It has since continued to grow and is now nicely in flower. In warm, sheltered positions in the Isle of Wight I have seen large examples of this plant, with a stem of considerable size, which at first surprised me greatly; but I was not prepared to witness the same plant enduring from 20° to 32° of frost in the county of Middlesex with impunity. After such an experience one is led to inquire whether, by affording slight protection in winter at the base, this plant may not be usefully employed in our shrubberies. At any rate, on warm soils it is worth a trial.—E. J.

ORCHIDS.

NOTES ON DENDROBIUMS.

MANY of these are now approaching the end of their season's growth, while others are still a long way behind. The evergreen short-bulbed species and varieties are many of them very quick in growth, and it is not uncommon for them to make two sets of growth in a season, especially if grown in the same house as the deciduous kinds. *D. aggregatum* is one of the smallest growing, and takes only a few weeks from the time it starts until the little pseudo-bulbs are complete, and with this it is inadvisable to let them grow away again. In fact, with all Dendrobies it is much better to keep them to their annual routine as far as practicable, nothing being gained by the extra growth. *D. heterocarpum* usually finishes up early, and is better for a few weeks' rest before the flower-buds appear. The earliest plants of *D. nobile*

should as soon as the last leaves make their appearance be placed in the full sun and well watered until the stems are quite complete, when less heat and moisture are necessary to induce a thorough rest. *D. macrophyllum* and *D. Dalhousianum* are two sorts that are often late in growth, the latter especially rarely finishing much before the end of the year. As it does not, however, flower until the growths are at least two years old, this does not matter, for one set of stems is ripening and forming flower-buds while the other set is growing. *D. thyrsoflorum* and allied kinds are rather erratic in their manner of growth, several plants not yet having any sign of breaking. With this, as the last-named, there is not time now to get flowers upon this season's bulbs, though if started early and well ripened in autumn, the plants usually flower on the last year's pseudo-bulbs. The tiny-growing *D. pulchellum* requires a good rest before flowering, and so does *D. Falconeri*, but neither must be dried sufficiently to cause the pseudo-bulbs to shrivel. If these small-growing kinds were given less heat during the winter and more judiciously watered, there would be less cause for complaint as to their not thriving satisfactorily. What they all like is to be very firmly fixed to their adopted home, be it basket, block, or what not, duly excited into growth in spring and kept cool afterwards.

There are few Orchids, as a matter of fact, that require less heat during winter than *Dendrobium*s, many of them standing a few degrees of frost with impunity. Of course, no one would think of allowing the temperature to drop so low as this if it can be avoided, but anything above 48° is too high for the majority of these during the long winter nights. There are several of the genus that will not stand so low a temperature, and among these may be mentioned the Australian species, as *D. bigibulum*, *D. Phalenopsis*, and others, also the late autumn-flowering *D. chrysanthum*, which is frequently in full growth during the winter months.

Besides the difference in their manner of growth, careful growers will note also the varying kinds of roots, and endeavour to give each a suitable kind of rooting medium and receptacle to grow in. Many of the long-stemmed deciduous group with their small twining and interlacing roots, such as *D. Bensoniæ* and *D. crassinode*, delight in a rather close root-run, and are well adapted for the small shallow pans now so much in vogue for Orchids. Then we have such deep-rooting kinds, as *D. nobile* or *D. superbum*, that quickly adapt themselves to any style of pot or basket, but preferably those with plenty of depth. These, too, like rougher, more open compost, one allowing free passage for air amongst them. Another kind of root is that of *D. infundibulum* and several of the nigro-hirsute group, that though strong and robust-looking cannot endure to be covered with peat or moss to such a depth as in the kinds mentioned above. These like a shallow compost, the pots varying in width according to the liking of the several kinds and the strength of individual plants.

Some may be inclined to think that this observation of the likes and dislikes of such easily grown plants is needless, and consequently pot all alike, keeping up the temperature they think most suited to the majority and leaving the rest to chance. This may do for a time, but sooner or later the time of reckoning is sure to come, and such haphazard modes of culture will only have the effect of keeping the hardier and more easily grown kinds in health, while the more fastidious and weakly species will gradually become weaker, and it is then only a

question of time before they cease to be of any real value. I would, therefore, again urge amateurs to throw over what may be termed the collective mode of treating their plants, studying closely the wants of such species as are not usually satisfactory with them, and persevering in the treatment that their observations point to. R.

ORCHIDS AT LONG MELFORD.

THE amount of success achieved by interested amateurs in Orchid culture is remarkable, and I was forcibly reminded of this recently when calling upon Dr. Turner, of Long Melford, Suffolk. This gentleman's collection is not large, but each plant in it bears the impress of careful and attentive culture. Two small lean-to houses are all that are given up entirely to Orchids, though there are several others devoted to stove and greenhouse plants, the better class of fine-foliaged plants and Palms apparently coming in for a large share of attention. In the cool house a compact and excellently grown specimen of *Epidendrum vitellinum majus* was flowering freely, bearing six spikes unusually large and brilliant in colour. *Odontoglossum Harryanum* was in strong force, one plant having exceedingly large flowers, the sepals measuring considerably over an inch across, and of that deep maroon colour so much admired in this species. *O. crispum*, *O. Pescatorei* and others of this section are here well grown, those in flower showing a careful selection, whilst all are in the most robust health. Passing to the warmer division, the same robust health in the plants is observable. Several fine pieces of *Cattleya Gaskelliana* were in flower, the colours very rich and varied, while *C. labiata autumnalis* gives promise of great things in the near future. A large and well-flowered plant of a good variety of *Brassia verrucosa* deserves note. The plant referred to was growing in a 6-inch pot, and the head of bloom must have been nearly 3 feet across, six long arching spikes crowded with the elegant singularly-formed flowers, with less of the greenish tint on the sepals and petals than is usual with this kind. *Dendrobies* are well grown, but not many were in flower. A finely-flowered *D. Falconeri*, however, deserves note not only on account of the number of blooms, but the health and vigour of the plant. *Odontoglossum Roelzii album* is also quite at home and flowering freely. Several others that usually flower at this season were represented, and doubtless there might have been many more, but Dr. Turner wisely considers it best to have the plants left to bloom another year and cuts the flowers after they have been a reasonable time upon the plants. R.

ZYGOPETALUM MAXILLARE.

It is unfortunately the exception rather than the rule to see this beautiful old species thriving under cultivation, but one occasionally meets with it in good condition. The habit of the plant is rather peculiar; it produces a creeping rhizome upon which the small ovate leafy pseudo-bulbs occur. The blossoms, produced on erect scapes from the base of the matured pseudo-bulbs, are each about 1½ inches across. The sepals are greenish with large blotches of chocolate, the lip rounded, blue with a deep purple crest. The flowers last a long time in perfection, but should not be allowed to remain on the plant too long. This *Zygopetalum* is usually kept too hot, the temperature of the Cattleya house being quite high enough at all seasons, and much better than that of the East India house. The habit of the plant is the cue to its requirements as to compost, all these creeping species abhorring a close, heavy mass of material about their roots. It is frequently found growing naturally on Tree Fern stems, and this mode of culture is also adopted under cultivation. Where these are growing in a temperature as described above they are the best of homes for this Orchid, but to wire the plants to the stems in a dry conservatory, as I have seen on

more than one occasion, is quite as bad for the Orchids as the Ferns. If suitable lengths of Fern stems can be procured and these sunk into pots, the bottom of each being surrounded with crocks and a little Sphagnum, the plants often thrive for many years, or they may be wired to cork blocks with a little Sphagnum, not all over the block, but in places, so that the roots have the choice of Moss or cork, the Sphagnum keeping a little moisture near them. Baskets are sometimes used, and if the plants are sufficiently vigorous to take to the compost they do very well, but small or weak plants do best as described above; the roots are then dry for an hour or two in the day, which is very conducive to the health of all epiphytal kinds if there is a sufficiency of moisture in the atmosphere. A great deal of care is necessary in ventilating a house where such plants as these are growing, especially if a steep pitched narrow structure. These part with the atmospheric moisture very readily, and while plants growing immediately above a moist stage may be adequately supplied in this respect, those near the roof will be parched from want of moisture. An important point in the culture of this Orchid is keeping the atmosphere well supplied with ammonia by the usual means. I have frequently observed that the nearer a plant comes to a true epiphyte the greater the advantage accruing to it from this source, *Cypripediums* and other terrestrial Orchids not benefiting in a like degree. In most houses there are places where a little soot and lime may be sprinkled about, this being a capital agent for supplying the ammonia and also distasteful to slugs. *Z. maxillare* requires an abundance of water at the root if growing as described above and must never be dried off even in winter. It was introduced from Brazil in 1844. R.

#### LÆLIAS.

THIS splendid genus contains some of the most popular and beautiful Orchids in cultivation, and no collection can be worthy of the name unless some of them are included. The larger growing species are gorgeous, while the smaller kinds are surpassingly beautiful and useful for cutting for almost every purpose for which cut flowers are likely to be required. As regards their structure botanically, *Lælias* closely resemble *Cattleyas*—indeed, some botanists have included them with that genus. Some of the species, too, greatly resemble *Cattleyas* in habit, and this section thrives under similar conditions as to compost and temperature. The dwarfer-habited kinds, such as *L. anceps*, require usually less heat than *Cattleyas* and rather different treatment. They are, in fact, rather more difficult to grow unless certain details of culture are carefully attended to. None of them like a great amount of rooting space, and if grown in pots the compost layer must only be superficial and the drainage must have special attention. Possibly the best of all modes of growing them is on trellised rafts, so that the roots have always plenty of air moving about them, and are not hampered by closeness of material. *L. autumnalis*, for instance, delights in this treatment, and will in this way be more satisfactory than if grown in pots or pans. During the growing season they must have abundance of air and sunlight, otherwise it is useless to expect flowers. If this is carefully attended to the temperature is really of secondary importance, but all of them will thrive in a maximum summer heat of 75° by day, 60° by night. This will induce a solid growth, the foliage taking on a bronzy or russet hue that is a sure sign of health, much preferable to the light green colour of plants kept in a strong, moist heat. Owing to the amount of sunlight they need and the freedom with which the air

currents must play over the roots, they need very frequent examination for water, twice or even thrice daily when growing freely. When the pseudo-bulbs are quite finished, such of these as do not produce the flower-scapes at once may be kept nearly, if not quite dry at the roots. A few weeks' exposure to the open air is also very desirable, the plants being arranged in a pit from which the lights have been taken off or in any other sheltered position. Here they may remain until early frosts are impending, when they must again be placed under glass. Many of the *Lælias* flower during the autumn and early winter months, and on this account are valuable, as this is the time when good Orchids are scarcest. Among these may be noted

*L. AUTUMNALIS*, which greatly resembles the spring-flowering *L. anceps*. The flower-spikes spring from the apex of the newly-formed pseudo-bulbs, and attain a height of 1 foot to 18 inches, bearing eight or ten large flowers. In the type these are rosy purple in ground colour, the lip being very attractive; the front of this is streaked with purple, the side lobes white and the centre bright yellow. It is a variable kind, several varieties having been named. All are fragrant, and the flowering season extends from July until November. The type was introduced from Mexico in 1836.

*L. DIGBYANA* is a very remarkable Orchid, known perhaps better as a *Brassavola*. The labellum of this is deeply fringed, the colour being sometimes pale purple on the sepals and petals, the lip creamy white. This plant delights in plenty of heat and sunlight, being a native of Honduras, whence it was introduced before 1846, this being the year in which it first flowered at Minterne, in Dorsetshire.

*L. FLAVA* is a pretty late autumn-flowering kind, a native of Brazil. The pseudo-bulbs are rounded and bear erect spikes of flower about 18 inches in length from the apex. The flowers are wholly yellow and last well. Though introduced as far back as 1839, this kind is not common even now. It requires *Cattleya* house treatment and is easily grown. Another Mexican kind, somewhat similar to *L. autumnalis*, is

*L. FURFURACEA*, which was introduced from the neighbourhood of Oaxaca in 1838. The outdoor treatment after flowering suits this kind well, provided there is time, but it must not be left out after the middle of September. The colour of the flowers is deep rose, the lip purple in front with a white base.

*L. PERKINI* is a fine species in its best forms and well worth growing. This has the habit of a *Cattleya* and produces a four to six-flowered scape, the individual blossoms being from 5 inches to 6 inches across, light rose on the sepals and petals, the lip similar in ground colour with a deep purple blotch on the front lobe, the throat white, with a yellow marking. This species comes from Brazil and is very variable, the pure white form being much prized and very rare. H.

#### NOTES FROM A NEW ZEALAND GARDEN.

##### AN ECHINOPSIS.

FEBRUARY 16.—One cannot always have one's favourite flower in bloom unless, indeed, the favourite happens to be *Primula obconica*, when, with a little care, the thing might be managed. Speaking for myself, however, I am virtuously conscious of a catholic taste in plants, nothing that grows coming much amiss provided only it keeps within reasonable bounds, so that when I cannot have Daffodils I can put up, in default of better, with a Rose or something of that kind second best.

There is, fortunately, no lack of beautiful flowers to bridge the six months' interval between Daffodil and Daffodil. For the last three weeks the *Romneya* has been producing its exquisite pop-

pies. I see that, like others of its tribe, it prefers the night season for bursting its chrysalis case and spreading its wings. If there is anything amongst flowers more exquisite than this, even amongst Daffodils, I should be glad to know it. By the way, it is noticeable that the *Romneya* does not appear in the list of plant names in Miller's dictionary. We call it here the Californian Poppy, to which name from its affinities it seems to have a good title. I see, however, that this English name is given by Miller to *Eschscholtzia*.

But the flower which stimulates me to dip my pen this morning is a Cactus, some kind of *Echinopsis*. I never meet a dealer in plants here who knows a *Cereus* from a prickly Pear, the Cactus, I suppose, not being a good trade commodity; so that I got this plant of mine with the vague information that it was "white flowered." It is, however, I think, *Echinopsis Eyresi*—at any rate an *Echinopsis*, and this morning I see it in flower for the first time. I grow a tolerably large and varied collection of Cactuses, but I confess that if I did not find great interest and beauty in their quaint form of growth and in the infinite variety of their spine arrangements, I should not see in their flowers sufficient inducement to grow them, this partly because many of the kinds—much the greater number, it seems to me—are so shy-flowering, and partly because the flowers when they appear are so evanescent. One of the most abiding impressions ever made upon me by a flower was that caused by seeing some years ago a *Cereus* in bloom in a Sydney garden. It was *Cereus triangularis*, I believe, and the plant was so large that it covered the outside of a garden bush-house. From day to day I watched the upright swelling bud-knobs, dotted here and there over the plant, like the cones on a Nordmann Pitch Pine. At last one evening, in the dusk, the great things opened. A ladder was brought and some of the blossoms were gathered. What their dimensions were exactly I did not ascertain, but the flowers were very large and splendid, soft cream-white in colour and exquisitely tasselled inside the cup.

The *Echinopsis* I have before me now has not such an imposing blossom as that of the Sydney *Cereus*, but it is still one of the most beautiful flowers I have ever seen. It presents in a marked degree that piquancy of contrast between exquisite flower and rough stem (if stem it be) that is characteristic of most Cactuses. Shaped as you cannot properly call the regularly ridged and spiny cushion that stands for the whole apparatus of stem, branches, and leaves, for it is mathematically exact in its ridges and valleys, which run north and south to the respective poles with a curvature as regular as the meridian lines on a globe. From the side of this globular hedgehog, apparently at haphazard, projects, at an angle of 45° or so, the cornucopia of the flower to a height of something over 5 inches. The stalk of the funnel is greenish white, dotted at intervals like crinine with tufts of dark hairs. The mouth of the flower is 3 inches across from petal tip to tip. The petals in three rows are white, faintly tinged with green like a *Devoniensis* Rose, and the whole is (in literal truth) a horn of plenty, for the inside is quite full of stamens encircling a conspicuous ten-rayed stigma, which rises in the centre, well above their reach, in silent protest, I suppose, against any attempt at self-fertilisation.

*Echinocactus sinuatus*, also in bloom with me, has not the great beauty of the *Echinopsis* I have just mentioned, but its straw-coloured satin flower, with a warm crimson stain at the base of the petals, is not to be despised. This Cactus has the merit of growing fast and flowering freely. My plant has been in bloom off and on for three months, as there are still three unopened buds that will take a month at least to come to perfection. *E. sinuatus* it was called by the American firm that sent it to me, but wrongly, I believe. If it is correctly named, then Mr. Watson, of Kew, is wrong in his description, which is not likely. A. WILSON.

*Dunedin.*

STONELANDS, SUSSEX.

It is pleasant to get out of the conventional in gardening, and there are many ways of effecting this. Generally gardens are cut off from all sympathy with the surrounding country—that is to say, the usual arrangement of our gardens is so stereotyped, that it is rare to find anything which is suggestive of the country and surroundings as gardens might well be. Among gardens we have seen in the southern country, this place is very characteristic of the woodland district of Sussex, and very pretty with its groups of Scotch Firs behind the house and in intimate connection with the farm buildings near. The house is pretty and of the best Sussex order—bright,

BOOKS.

TRAITE DE CULTURE POTAGERE.\*

This is an excellent little book, and deserves an English translation. The author is a member of the teaching staff of the Grignon National School of Agriculture. His style is simple and concise. The pleasure of growing one's own vegetables is one which scarcely any amount of partial failure can destroy. The amateur should feel consoled for repeated disappointments, since, according to this author, he is a powerful factor in the world of horticulture, because it often happens that failures through inexperience and imperfect knowledge only incite him to renewed attempts, until in the end he feels strong enough to forsake the beaten paths and strike out a way of his own among new and untried species. In this he has an advantage

he devotes to his business place him in the first rank. For him the seasons do not exist; he is busy at all times in his garden, from which he sends out a continuous supply of fresh vegetables to our markets.

To all classes engaged in the cultivation of vegetables this book may be recommended. The different vegetables are treated in alphabetical order; their uses, varieties, mode or ways of culture are then described in a lucid manner, and the student is greatly assisted by the numerous excellent engravings with which (through the kindness of MM. Vilmorin) the author enhances the practical value of his book. We take the following chapter, page 148, on

WILD CHICORY.

Wild Chicory (*Cichorium Intybus*) is found growing wild in France as well as in England.

USES.—Cultivation has singularly modified the characteristics of the plant. The leaves, whilst

Stonelands (south side), Sussex. Engraved for THE GARDEN from a photograph.

sunny windows, pretty stone, big chimneys, simple, direct and right in all ways as regards the building.

As will be seen from the little engraving, there is a terrace, rendered necessary by the slope of the ground, the wall of which terrace also cuts off the house from the road to the farm buildings near. The effect near or far is very pretty. Stonelands is a fifteenth century house, of the history of which nothing can be gleaned. It is probably of about the same period as Wakehurst and other houses in the neighbourhood, and occupied by yeomen till of recent years, when it was purchased by Mr. Franks, repaired and in various ways much improved by him.

over the professional grower, who cannot afford to spend his time and capital except in undertakings known to be profitable to him. Thus, according to M. Dybowski, the amateur prepares the way for the professional, and so, without taking into account the benefit which he personally derives from the exercise of his intelligence and perseverance, the amateur's part in horticulture is an important one. Of the two classes of professionals—the market gardener and the cultivator—the former is the artist. His operations may be limited in area, but the scientific nature of his methods, the capital he invests, and the trained intelligence

increasing in size, have become less hairy and their bitter flavour, too, has diminished. With these modifications the plant lends itself to a variety of uses for cooking. In a young state it is eaten raw as a salad, and one way of preparing it is to cover it over with earth in order to blanch the leaves as they grow; but, as a rule, this blanched appearance is got by growing the plants in cellars, and it is generally after having undergone this process that it reaches the consumer.

VARIETIES.

Besides the type several distinct varieties are cultivated.

VARIATED WILD CHICORY.—The leaves of this variety are much spotted with red. It is used for obtaining the Barbe de Capucin, and the red stains remain on parts in spite of the blanching process which the plant has undergone.

IMPROVED WILD CHICORY.—This variety is characterised by the breadth of its leaves, which

\* "Traité de Culture Potagère (Petite et Grande Culture)." By J. Dybowski. Illustrated with 113 engravings; 2nd edition. G. Masson, 120, Boulevard Saint-Germain, Paris.

by their undulating and crisp appearance impart to it the semblance of a Lettuce.

**THE WILD LARGE-ROOTED CHICORY, OR COFFEE CHICORY.**—This variety, the tap roots of which attain to a very large size, is used, as its name implies, in the preparation of coffee, in which state it is widely consumed. Its leaves also are used in the production of Barbe de Capucin. There are two types of the plant, viz. :—

**THE LARGE-ROOTED BRUSSELS CHICORY OR WITLOOF CHICORY.**—This plant, which resembles the Magdeburg Chicory, has this in particular, that the leaves form a heart which imparts to it something of the appearance of a small-sized Lettuce. At a later stage we will describe the method of cultivation employed in respect to this variety.

**BARBE DE CAPUCIN.**—The cultivation of wild Chicory for Barbe de Capucin is limited to the neighbourhood of Paris, the communes of Montreuil-sur-Seine, Rosny and Bobigny. Cultivators who devote their energies to its production rarely sow Chicory on their own lands, one reason of this being that oftentimes they do not possess the requisite amount of space, but chiefly it is owing to the exhausting effect of this cultivation which makes it impracticable to employ the same plot of ground for two consecutive years. The ground which is set apart for this purpose is limited to one crop, that is to say, from spring until the end of autumn. A plot is given over to the cultivator in April and is manured, ploughed over, and then harrowed. The lease of each plot ceases in November or December. The price of each tenancy varies very little, ground which is set apart to this crop being always of good quality, and the average price is 750 francs the hectare.

#### SOWING.

The ground having been properly prepared, the seeds are sown at the end of April or beginning of May. They are sown in lines in order to enable the ground to be kept clean, which is done all through the summer. The lines are 0.30m. apart and the quantity of seed which is required per hectare is about 150 litres, at an average price of 1 franc the litre. The sowing, which is done by hand, employs one man from nine to ten days. In operations on a large scale it is better to sow with a drill. Shortly after the appearance of the young plants, which generally takes place eight or ten days after sowing, it is advisable to hoe between the lines, which means eleven days' labour for one man. A month afterwards it is necessary to get rid of the weeds which may have made their appearance between the lines, or it may be in the lines themselves among the roots of the young Chicory. This weeding, which is done by hand, occupies one man about fifty days if it is properly done. The leaves when they have attained to a considerable development are either gathered by hand and sold as young Chicory for salad, or they are reaped with the scythe as food for cattle. This latter as a supplementary crop is sometimes not to be despised.

#### LIFTING THE PLANTS.

At length comes the time of blanching, an operation which necessitates constant care throughout. The first step is the lifting of the plants. This is done either with the spade or by means of a flat-pronged fork. Having loosened the earth by means of either tool, the plants are easily lifted by laying hold of the leaves that remain. This is either done from time to time as the plants are required for consumption, or all at once, in which latter case the roots are placed in a basket close to the place where it is intended to make use of them. In any case it is a long and costly operation. It takes one man not less than a day and a-half to clear 4 poles of Chicory, since he has to tie the roots with willow into small bundles. In this way about 1350 bundles per hectare are obtained, and these, so soon as the lifting is over, are conveyed to the place where the forcing is done. At Montreuil, cultivators who have not their own means of transport are accustomed to employ carriers at the rate of 12 francs for each fifty bundles. When the bundles have reached their destination near

the blanching places, the next step is to trim the roots, and this is done by taking each plant separately and nipping off all the leaves which still remain with the finger and thumb, as the use of a knife might injure the heart or centre, and thereby retard the appearance of leaves. This work is usually done by women and is paid for at the rate of 1 franc the bundle. After each bundle is made up it is again tied with willow in such a way that the plant tops are level with one another.

#### FORCING.

This takes place in a cellar or store-room, the apertures of which have all been closely sealed, and upon the floor of which a bed has been made, covering it wholly or in part, according to requirements. The bed ought to be of fresh stable manure and have a depth of 0.30m. to 0.35m. When, after having been carefully pressed down and watered, the bed has attained to a fixed temperature of about 20° to 25°, the bundles of Chicory are placed side by side upon its surface and as close together as possible, with a view to economy of space. Some producers fill up the spaces between the bundles with smaller bundles. It is seldom that the beds are completely covered the same day, and, in fact, the custom is to commence one side and follow up with the others, in order that all the plants may not reach maturity at one and the same time. When all the Chicory is bedded, care is taken to close every door and stop up every aperture, in order to prevent the least ray of light from penetrating to the plants, as that would have the effect of "greening" the leaves. As soon as it is placed on the bed the Chicory begins to sprout with such rapidity, that one may, so to speak, almost see the sprouts coming. At the end of eleven days, if the bed is hot enough, the leaves will have attained a length of about 0.30m. Whilst the forcing is going on care will be taken to water the plants once or twice a day, having regard to the heat of the bed, and only perfectly pure water should be used, as the least impurity would induce rotteness in the leaves.

**PREPARATION FOR THE MARKET.**—As soon as the leaves have attained the length above mentioned the forcing process is at an end. The bundles are then removed from the cellar with great care, so as not to break the leaves, and are then untied. A small handful of the plants is then spread on a table, and on the roots is placed a layer of damp potter's clay of about half the size of one's fist, and upon it another layer of Chicory is spread. This is constituted the bottillon, which is tied round the roots with a slender band of Willow and placed among others in large baskets large enough to hold about 200 bottillons. Care will have been taken to line each basket with linen and to keep it covered, so as to avoid bruising the leaves and in order to exclude the light, as the least ray of light easily turns them green. So prepared, the baskets are despatched to the markets. Here, again, growers who have no means of transport of their own have recourse to carriers who, at Montreuil, charge at the rate of 5 francs for every four or five baskets. To the cost of carriage must be added the half-days of the salesman, amounting to 3 francs, which makes the cost of delivering 800 to 1000 bottillons about 8 francs.

**THE YIELD PER HECTARE.**—Such are the operations and the cost of cultivation, forcing and delivery. It is easy, therefore, to calculate the yield per hectare. Our computation is that in an average year it amounts to 1350 bundles, giving after the forcing 50 bottillons the bundle, or a total of 67,500 bottillons. These are sold in the Paris markets at prices which vary according to the severity of the winter and the competition they meet with from other salad stuffs. In years when the sale of Chicory is quiet it is sold at the rate of 8 francs to 12 francs the hundred bottillons. On the other hand, in years when the demand is great this price is doubled. From these facts we may set the minimum price down as 12 francs the hundred bottillons.

**THE EXPENSES OF CULTIVATION, &c.**—This may be calculated per hectare as follows, it being re-

membered that the price of a day's labour of one man is 6 francs at Montreuil.

The hire of 1 hectare of ground, ploughing, manure, &c. ... ..	750 francs.
150 litres of seed at 1 fr. ... ..	150 "
Sowing, 10 days' labour of one man at 6 frs. ... ..	60 "
Hoeing, 12 days at 6 frs. ... ..	72 "
Weeding, 50 days " ... ..	300 "
Harvesting, 150 days " ... ..	900 "
Transport of bundles at the rate 5 frs. per 50, on a total 1350 bundles ... ..	324 "
Cleaning, at 1 fr. the bundle ... ..	1350 "
16 metres of manure for forcing, at 5 frs. ... ..	80 "
Willow for tying bundles and bottillons ... ..	40 "
4 metres of cubes potter's clay ... ..	20 "
Carriage to market, 1 fr. for the 100 bottillons ... ..	670 "
Total ... ..	4716 francs.

**PROFITS.**—Roughly speaking, the profit from 1350 bundles the hectare and fifty bottillons the bundle, or a total of 67,500 bottillons, at the rate of 12 francs the 100, may be set down as 8100 francs. If from this sum we deduct the expenses, the net profit per hectare will be 3384 francs. All the above details have been furnished us by M. Clement Guyot, cultivator, of Montreuil-sous-Bois (Seine). The figures may vary much according as the work is done with more or less care, and the fact is that under different conditions, the totals above given may be very appreciably diminished. Another grower in the same locality puts the yield per hectare as not more than 36,000 bottillons. It is true that in his case the expenses of cultivation are much less, their total not being above 3270 francs. Consequently under like conditions the profit is not above 1050 francs on the same calculation of an average of 12 francs the 100 bundles. The daily consumption in Paris alone is about 80,000 bundles of 50 bottillons during the winter.

In the production of Barbe de Capucin, the large-rooted Chicory is used as well as the wild Chicory proper.

**THE CULTIVATION OF CHICORY FOR CUTTING.**—A practice which is carried on more or less continuously in kitchen gardens, as well as by cultivators for the markets, consists in sowing Chicory in March, sometimes in rows 0.25m. to 0.30m. apart and sometimes broadcast. Weeding and hoeing go on during the summer when the leaves are cut for the consumer, and in winter the ground is cleared to the extent of removing the dead leaves. In February and March the Chicory is covered over with leaf-mould or with mould simply when the seeds have been set in lines. The thickness of the cover ought to be at least from 2 inches to 3½ inches. At the end of two or three weeks the Chicory will make its appearance, and then is the time to gather the leaves. The plants are laid bare and the leaves are cut, but avoid removing the heart, which is covered up anew. Thus two or three crops may be had in the spring of a salad which is perceptibly bitter, but is generally liked. The same operation may take place in the following year with the same plants, after which they should be rooted up. The varieties which are found successful in producing Barbe de Capucin may also be used for this purpose, but in any case it should be with the addition of the improved Chicory.

**THE CULTIVATION OF WITLOOF.**—This is a vegetable much used in Belgium, and promises to have an equal popularity in France. Its cultivation, however, is attended with difficulties, not in the manner of growing it, but owing to the difficulty there is in obtaining seed which is absolutely pure and carefully selected. The result of cultivating an inferior kind is to produce a vegetable resembling Barbe de Capucin, a variety which is wanting in stability and has a tendency to go back to the type. So far the results obtained in France have not been so successful as those which come to us from Belgium. The sow-

ing is done as in the case of the wild Chicory. In the autumn the roots are pulled up in the prescribed manner, and choice is made of all those the diameter of which is at least 3 or 4 centimètres in the upper part; all others are cast aside, as well as those which instead of only one centre shoot have several. The selected roots are trimmed as in the case of the Barbe, and then they may be dealt with in two different ways. One way consists in adopting the same system of forcing as is applied to the Barbe in the manner described above. The other consists in first reducing the roots to an equal length of 0.20m. to 0.25m. by cutting off the thin ends. This done, a trench is made 0.40m. in depth in which the roots are placed upright side by side, the spaces between being filled with earth and the trench filled up again. In this way the plant is covered with a depth of earth of about 0.20m. Where it is desired to force the growth, the surface of the trench is covered with a warm layer of horse manure, varying in depth according to the quickness

tings, after which the roots are pulled up and thrown aside. After this first crop a second may be grown on the same bed after turning up in order to renew the heat. It is better to make two successive sowings rather than cut too long from the same plants, since the older these are allowed to grow, the harder and more bitter the leaves will become.

The seed of the wild Chicory retains its germinative power for six or seven years. It is got from plants sown in the spring and which have stood the winter in the open air. For obtaining the improved varieties and for Witloof Chicory, the best plants should be selected and replanted at 0.30m. in the spring of the second year.

THE NEW HERBACEOUS CATALOGUE.\*

In this handy shilling volume we find arranged in alphabetical order a catalogue of about 6000 kinds of herbaceous, alpine and bulbous plants which are cultivated in the open air in the Royal

a climate where the plants are all through winter liable to be excited into premature growth by spring temperature, again to be checked by the prevailing east winds of March, which carry, in addition to their own withering powers, a load of impurities gathered as they pass over London. It is but fair that these disadvantages should be borne in mind, and that those who know how difficult it is to grow alpine in any lowland situation will appreciate the success with which so large a collection is maintained in the gardens at Kew.

The plan of the catalogue should be briefly noticed. The names of the plants are arranged in four rows. That which begins nearest to the left hand margin of the page contains in full the generic name of the plant, followed by that of the first species. In the next row from the left are the rest of the same genus. In the third row are well-known botanical varieties classed under the species to which they belong, whilst in the fourth are added in a few cases synonyms. If all the synonyms were added the volume would be three or four times as large as it is, and would be very confusing. The few which are given are in cases where the priority of name is in dispute. The specific names of all the plants are followed by the abbreviated names of the botanists who first described them and of the country of which each kind is a native.

It is to be hoped that all who cultivate hardy plants will avail themselves of this volume, by which the naming of their plants may be made uniform, the spelling correct, and the mode of writing the specific name, whether with a capital letter or not, may conform to a regular rule. Let every name by which a plant is known in a nursery or a private collection be verified by this list. If it does not occur in the list, the chances are twenty to one that it is wrong, and in this way we may hope in time to eliminate the very large number of unauthorised names now prevalent.

Attention may also be called to the account given in the preface to the catalogue of the way in which this large collection has been got together, and it is hoped that all who have rare plants to spare will help to maintain and enlarge this finest show of living plants in the world.

*Edye Hall, Malpas.*

C. WOLLEY-DOD.

ORCHARD AND FRUIT GARDEN.

THE NEWTOWN PIPPIN.

This still stands at the head of all American Apples in flavour and quality. We read of your famous Blenheim, Cox's Orange, and Ribston Pippin, and your correspondent "W. G. C.," who in December last had been comparing our Newtown with some of those choice English Apples, said, "In justice to the Newtown Pippin it must be said that it was of excellent quality, only slightly behind Cox's Orange, Ribston Pippin, and one or two other highly flavoured varieties grown in this country." I do not like this conclusion, and therefore I believe it is unjust, although I frankly confess that no such opportunity for comparative test was ever presented to me. But in any event I want to protest against the statement that our American Newtown is "slightly behind" any other Apple for flavour and quality in general. Of course, I realise what a wide diversity of tastes and opinions there are regarding the ideal flavour of an Apple, nor do I believe it possible to settle upon any standard. But in this case, assuming that the writer had carefully selected and well-grown specimens of the Newtown for his test, allow me to say that at that early stage of the winter our Newtown could not have reached its full flavour. It is rarely before the latter part of January or 1st of February, in this latitude, that its rich, sprightly juices are fully ready to delight the palate most.

Apple Newtown Pippin. From a photograph sent by Mr. H. Hendricks, Kingston, New York.

of growth required. With a layer 0.50m. deep, it will take on an average a month in February to give us a vegetable fit for the table. The roots having been withdrawn from the trench, the leaves are detached, and either eaten raw as a salad or cooked.

CULTIVATION IN BEDS.—Sometimes the wild Chicory or its variegated variety is sown in beds and under frames. If so, the sowing is done from January to March. For that purpose a bed is formed 0.40m. in thickness, which, after being dressed with mould, is enclosed in a frame. The sowing is done broadcast, without lines; water is then sprinkled on the bed, which is afterwards covered with straw matting. The seed germinates in two or three days, and fifteen days afterwards the young Chicory is ripe for cutting and being eaten as salad. It will furnish two or three cut-

Gardens at Kew. In the first place such a list is a record of which the managers of Kew may fairly pride themselves. The soil of that part of the Thames valley is not very good for most herbaceous plants, but it is in the rock garden that the difficulties to be encountered are the greatest. Instead of the pure and light air of a mountain side, where the atmosphere is in summer often saturated with healthy moisture, and evaporation from the soil—a condition hateful to most alpine plants—is hardly perceptible, and where in winter the plants rest for several months preserved in a constant temperature by a covering of snow—instead of this we have at Kew an atmosphere within the baneful influence of smoke-laden fogs,

\* "Hand List of Herbaceous Plants Cultivated in the Royal Gardens, Kew." The Royal Gardens, Kew.

It is distinctly a late winter Apple here and a very long keeper, coming in when nearly all other Apples are gone; and this is another important element of its great value.

Last October I purchased a barrel of the finest Newtowns I ever saw or heard of from an honest old farmer who grew them about ten miles from this city. I have raised many fine ones in past years, but nothing to equal these. Every Apple was sound, well coloured, fair, smooth, and beautiful, fit for the show table. Two dollars was all he asked for this barrel of Apples, and I paid him with pleasure. I kept the fruit headed up in an ordinary cold room, with the usual fluctuation in temperature, a part of the time at freezing point, until February, I think. But then when I opened that barrel there were indeed a sight and an aroma fit for the enjoyment of pomological savants, and I wish President Berckmanns, of the American Pomological Society, "W. G. C.," and other friends of that ilk could have been there to see, smell, and taste. Every specimen sound and beautiful, and the flavour beyond compare in my estimation. From that time to this (June 15) I have been enjoying this fruit. And now, when all other Apples have disappeared from the markets, I have yet two or three dozen of these magnificent fruits, sound as a dollar, though the mercury has been simmering in the nineties for days together. I herewith present an accurate outline of one of these Apples, an average specimen, and also a photograph of three other average specimens, which are shown slightly under the actual size.

You will observe that these specimens are much larger than the typical outlines of the Newtown shown in "Downing" and other standard pomological works. Does this look as though the Newtown Pippin had deteriorated very badly in this country in recent years, as we have been led to believe by various writers? Now, the grower of these Apples is a plain, modest farmer who has never heard that the Newtown was a poor, unprofitable Apple to grow. He does not read the horticultural papers very much, and does not farm on the most approved scientific principles. All this is pretty clear in view of the fact that he sold such magnificent Apples of this choice variety at such a low price, which was only a few cents more than other standard sorts were bringing at the time. He has several Newtown trees in his orchard here in the shadow of the Catskill Mountains, planted on rather high ground, and they get the same general treatment which is given to his entire orchard; he just lets them bear fruit like the other trees. That is all. But I am going to tell him that he can just as well get more money for such Apples in future, because he ought to know it, and then I somehow feel as though I owed him something. Why, when I opened those Apples every one was worth five cents in the fancy fruit markets here, and the larger ones would have sold for ten cents each from the New York stands. Twenty-five dollars would have been a small price for that barrel of Apples.

Does it not pay then to grow the Newtown? But you say, these were very carefully sorted, and I agree that they must have been; it always pays to sort fruit carefully. But granting all that, this man had plenty more like it; mine was only a sample of his entire crop.

Now I believe the Newtown has been and continues to be very unjustly condemned as an unprofitable market Apple in this country, though it is starred in fifteen of our States, and double-starred in three of them, in the American Pomological Society's catalogue. That the tree is a rather slow grower and shy bearer while

young I admit, but when it begins to bear it continues to produce its precious load and is fully as productive as other leading sorts. It is an ironclad in vigour in the severest climate and is not subject to disease. Therefore I claim, because of the superior value of the fruit, it amply repays for the extra year or two required for its maturity. All this I have said before in previous issues of THE GARDEN, and subsequent experience and observation have fully confirmed it. I can point to several comparatively young orchards of the Newtown here on the bank of the Hudson River in the suburbs of this city which are not equalled anywhere in vigour, productiveness, and value of their crops. From one of these fine orchards Apples are annually sent to the royal table of Her gracious and excellent Majesty the Queen, and I am proud to know that she has the best.

For nine months ending September 1, 1894, Great Britain is said to have paid us about 2,500,000 dols. for American Apples. During the past year we have shipped you nearly 1,500,000 barrels of our Apples. I wish it were possible to know just how many of these were genuine Newtowns and how many more were sold as such. If you have choice English Apples that are really superior to our Newtowns, why is it that none of them are ever imported or sent to this country, where we usually try to "get the best?"

Kingston, N. Y.

H. HENBRICKS.

**Pears and Apples.**—The same treatment cannot be given these fruits as advised for other wall trees, as if the knife is used too early it does not promote fruiting wood, but a mass of weak leafy wood. Leaders should be secured to the wall and weak useless wood cut out. Leave any shortening of terminals till later on when the wood is more matured. On some Pears, such as Louise Bonne of Jersey and other smaller kinds, heavy crops have set and thinning of fruits is necessary; other kinds with a sparse crop are making much growth, and in their case the removal of breast wood will be necessary. Cordon trees should be kept well stopped, the terminal growth secured, and the crop where heavy thinned, as after the middle of this month there is little danger of dropping. The early kinds, such as Doyenné d'Ete and Jargenelle, should be thinned earlier. The trees should be well mulched and ample moisture given them, with occasional dampings over after hot days. Much the same remarks apply to bush trees of both Apples and Pears as to thinning, mulching and watering. Pyramids and bush trees may have gross top growth reduced, but it is well to keep the wood thin in preference to shortening it much at this season.—G. W.

**Summer pruning.**—I have often thought that much harm is done to valuable fruit trees on walls and espaliers by removing the whole of the breast wood at one time. This always has been and is still the rule in most gardens. If, however, it is necessary to remove the young shoots from a Peach or Nectarine tree piecemeal in order to avoid a sudden check, the same rule must, I think, hold good in the matter of summer pruning. In fact, I have frequently noticed that the fruit on Pears which was swelling freely up to the time of removing the foreright shoots became stationary for a considerable time after the operation. Far better would it be in my opinion to go over the trees, removing one half the shoots more from the top half than the bottom, completing the work in ten days or a fortnight's time. I am confident that some of the more delicate Pears and Plums also resent this wholesale defoliation in a most marked manner, the fruit never afterwards attaining to its normal size or developing its best flavour. I will go further and say that it would be wise not to allow varieties which are prone to make much wood to have their own way in spring, practising pinching as in the case of pot trees

and trees generally grown under glass. Thus sun and air would be able to act beneficially on each shoot and leaf, a thing impossible under the crowding system, and as the more wood a tree makes the more it is inclined to, this early pinching would lessen the liability to grossness and secure a more evenly balanced condition of the tree generally. Many young fruit trees are undoubtedly stunted and never permitted to attain their full dimensions by this unnatural raid on their constitutions from the very time they are planted.—J. C.

**Preparing Strawberry plants.**—In this neighbourhood Strawberries are largely grown, both in the open and under glass. The method of raising young plants that finds the most favour is that of layering them in the open ground as early as possible. Not only is the small pot system of layering Strawberries expensive, but the plants so raised do not take so readily to their altered condition as when lifted direct from the open ground. Directly runners can be obtained the soil underneath them is loosened 1 inch or so deep to ensure a quick root action. A slight hollow is made in the soil to assist in giving the runners water at first when they are layered. The layers are made fast to the soil by the aid of a peg pushed into the ground immediately behind the runner. In a few weeks the roots will have pushed sufficiently far to enable the plants to be lifted with some soil attached, so that when planted either in the open or in pots the check of removal is not felt. The roots run quickly away in the fresh quarters, owing to their not being entwined around each other as when the plants are in pots.—E. M.

#### SOME GOOD CHERRIES.

THE season has not been all one could desire for Cherries, black fly having been troublesome, but there is no cracking, which is often the case in wet seasons. In no season have Cherries been more plentiful or better. I recently paid a visit to Gunnersbury House, and there I saw the finest Cherries I have ever seen in the open. They were equal to the best fruits grown under glass. Mr. Hudson showed them before the fruit committee of the Royal Horticultural Society on July 9, and was unanimously awarded a silver medal for them. The trees from which the fruits had been gathered were very old, and a few seasons ago suffered so badly from canker that Mr. Hudson feared he would lose them. To try and bring them round he laid in all the young growths at full length except the foreright shoots, with the result that the trees now are a mass of young fruiting wood; the old, somewhat unsightly branches are well covered over and there is a wealth of fruit, thus showing the advantage of giving trees more freedom, using the knife less and getting young wood. Of course, from orchard house trees one can expect first-class fruit, but in the open such finish cannot be expected. I am aware young trees are not to be relied upon in the open for extra large fruit.

When I exhibited Cherries some fifteen years ago I always relied upon one old tree with a few branches. This tree was near a manure tank and got food freely, but I am not aware Mr. Hudson's trees got any special food, and they had got none too much moisture, water being scarce and difficult to get at. The trees named on a west and south-west wall are very clean and free from insects. The varieties are Black Tartarian, Bigarreau de Schreken, and Bigarreau Napoleon. There were other varieties, but not such old trees. I do not think anyone who takes an interest in fruit culture can make any mistake in planting the above varieties. B. Napoleon is a later fruit, but in such seasons as this it is ripe by the first week in July on a very warm wall and in light soil. In my opinion it is the very best late Bigarreau. The Black Tartarian is generally considered one of the best black varieties for growing in a cool house. The other variety, Bigarreau de Schreken, which may be termed a very fine type of Early Bigarreau, is black and with a great

depth of flesh, very rich and juicy. It does well either indoors or out.

I find the above varieties do well in this locality, and I will add one or two more which I value quite as much for quality, cropping, and earliness. Early Rivers, a large black fruit, is a splendid variety, also Governor Wood, a most reliable variety. St. Margaret, a large dark purple, is very fine and crops grandly. To these should be added Frogmore Bigarreau, Empress Eugénie, Elton, and Waterloo. These are all grown on walls and never fail to crop freely; indeed, this season severe thinning was necessary. G. WYTHES.

*Syon House Gardens.*

**Strawberry British Queen.**—I never remember a season when the above variety has done so well and the flavour been so good. Many fail with this variety through leaving the plants too long in one place. There are none which repay annual planting better than British Queen. It is useless to plant weak runners. If a few plants are reserved for runner production, not fruiting them and planting the runners early in deeply-dug well-manured land, this old favourite will give a good return. I do not advise north borders where the land is heavy, but in light soils and a sheltered garden a north border suits the plants.—S. H. B.

**Strawberry Aberdeen Favourite.**—In the race for new or large kinds we must not forget those which do well in what may be termed adverse soils. The above is one of the very best croppers I have grown. Not only is the fruit freely produced, but it has that rich vinous flavour often found lacking in these fruits. This variety is much grown in the north, and is valuable, as it prolongs the season. It does well in most soils; in fact, I have never seen it fail in any locality, and the fruits being firm travel grandly. The fruit is bright red, conical, and of first-rate quality. With me it is in season after British Queen. Being a strong grower it requires ample space. The plants should not be allowed to bear more than two crops if fine fruits are desired. It is not grown in this part of the country so much as it deserves, but in my estimation it is much superior to Sir J. Paxton and others more often seen.—G. WYTHES.

**Currant La Conde.**—In his useful notes on Currants at p. 6 "W. G. C." mentions this variety, but does not speak of La Versailles. The latter variety I have grown for many years and find nothing to approach it either for cropping or quality. The fruit is produced in very large bunches, the individual berries being sometimes as large as small Cherries. I am wondering whether La Conde and La Versailles are identical, as "W. G. C.'s" description of the former would seem to indicate. La Versailles is by no means a uniform grower, being somewhat ungainly, but on this account may be easily layered in early spring, good rooted plants being thus obtained by the next autumn.—J. CRAWFORD.

**Melon roots diseased.**—I send you a piece of a root of a Melon. Whenever the Melons begin to rot, the plants always flag on hot days. I keep the house at 70° by night. I grow Cucumbers and Tomatoes in the same house. I never water within 4 inches of the stem.—J. P.

\* \* \* The Melon roots are badly attacked by a small worm, which was doubtless introduced with the soil. You keep your house at the proper temperature, but doubtless to a great extent the trouble is caused by the Cucumbers, these being more liable to this disease than Melons. In your note you state it causes dropping of foliage on hot days. This is simply from want of roots to support the plants. Can you not devote a separate bed to the Melons and thus prevent contamination, as it is impossible to do both plants justice quite close to each other? Again, you grow Tomatoes in the same house. This is not advisable, as I fail to see how justice can be done to these last-named, as they require more air, less moisture, and in a close, steamy atmosphere

would make much leaf growth and fruit very sparingly. The only remedy is when the crop is cleared to thoroughly clean out the old bed, burn the soil, or mix a quantity of fresh lime and soot before using it in any way. I would advise you to obtain soil from a new source, thoroughly exposing it to frost before using, and mixing with it some wood ashes, soot, or old lime rubble before placing indoors.—G. W.

#### NOTES FROM WORTHING.

WORTHING has long been noted as a great Tomato and Grape-growing centre, and having recently gone to reside there, it has occurred to me that a brief account of the now extensive fruit-growing industry carried on in and around the town might be of interest to many readers of THE GARDEN. The extent of glass in the neighbourhood is very large and would surprise anyone unacquainted with the place; indeed, I know of no other spot, even in Kent or near London, where so much glass can be found within a limited area. The nearest approach to it is, I should say, at Bexley Heath, or Swanley, in Kent, where Mr. Ladds' huge market and fruit-growing nursery is situated. Though none of the Worthing establishments equal this in extent, there are many growers possessing from 500 feet to 5000 feet run of spacious glass structures within a short distance of each other, even in and near the town itself; while in the surrounding hamlets of Tanning, Broadwater, Patching, Lancing, &c., large nurseries devoted to fruit growing—chiefly under glass—are also very numerous. The Worthing growers, indeed, must be counted by the score, and more houses are being erected almost daily.

Now why so extensive an industry should have become established here and have grown to such large proportions is a question that may fairly be asked. As far as I can see, there are two reasons: first, the climate is unusually sunny, dry and warm, with a remarkable absence of storms, plenty of fresh sea air, and no fog, except a slight sea mist at times. In a season like the present, indeed, a little more moisture would be desirable, for there has been less rain here than almost anywhere else, so that an abundant supply of water is an absolute necessity. The soil also—a substantial, but not heavy loam of a rich yellow or reddish colour, and in many places 3 feet to 5 feet in depth—is admirably adapted to the growth of plants in general, and of Vines and Cucumbers in particular. I fancy it contains rather too much iron to be quite the thing for Tomatoes, but as it varies considerably, this crop also succeeds admirably in certain spots. Secondly, it appears that in the good old times Tomatoes were found to succeed so well in the open air, that some of the inhabitants commenced their culture on a rather large scale, and for some years with great success and profit. But when the cycle of wet summers set in this was given up, and the disappointed growers then began erecting glass houses to shelter the plants, and have since added to this accommodation very largely. Both

#### GRAPES AND CUCUMBERS

are also largely cultivated, and with marvellous success and a considerable amount of profit also, though the low prices now obtainable have rendered it necessary for growers to greatly extend their accommodation and output in order to make the same amount of return. Grapes in particular are wonderfully well grown and enormous crops often obtained. Black Hamburgh is the general favourite, with a few Alicantes here and there, but Gros Colman is now being cultivated to some extent. I have never seen such grand samples of this variety as some of the Worthing growers turn out by the ton. The fruit is not only exceptionally large in both bunch and berry, but the flavour is really delicious and infinitely superior to the poor, insipid, watery Grapes too often met with, this being due no doubt to the rich ferruginous soil and almost unlimited sunshine. One of the best growers told me recently

that he could grow Grapes profitably at as low as 6d. per lb., but this is possible only by utilising the houses for forcing Roses in pots during the winter and spring and by growing Chrysanthemums in the autumn, both for cut bloom of course. Cucumbers, again, are grown remarkably well and owing to the glorious climate (the sun being often fully as strong in February as it is in April near London), the plants may be raised, planted, and cut from at any season with almost equally good results—barring, of course, the extra cost of uring in severe weather and the slightly diminished crop. Very little bottom heat is employed, one 4-inch pipe, covered with brickbats, in the bottom of each 4-foot bed, sufficing for even the earliest crops, and during the summer no artificial heat whatever is employed. A neighbour has been cutting continuously from one house between 200 feet and 300 feet in length since Christmas last until now, often 100 or 150 dozen of fine fruits weekly, and the plants are still full of vigour. Red-spider, thrips, &c., are almost unknown.

#### TOMATOES

also are very largely cultivated. As many as 40 or 50 tons of ripe fruit are often despatched from Worthing station per week during the summer months to London and elsewhere, and more than one of the larger growers sends away a ton or more of fruit twice, and occasionally three times a week at this season. The variety chiefly cultivated is a selection from the old Large Red, known locally as the Worthing Red, but here and there a large batch of Early Ruby, Perfection, or some other variety may be found. The Worthing Red is a dwarf and sturdy grower, setting very freely, and producing numerous large trusses of fruit, which, however, are usually more or less corrugated, the colour also being by no means first-rate. Some of the more carefully selected strains produce fairly smooth fruit, but in most cases it is decidedly coarse. Being a hardy and sure-setting variety, even in the depth of winter, it is, however, preferred by most of the growers to any other, but it does not realise the best price. A few years ago, when the rage for Tomatoes first set in and there were fewer growers, good prices were obtained. That troublesome disease known as the "flag" or "droop" causes some growers a great deal of anxiety and loss, one large grower having had an almost total failure from this cause for the last two or three years. In other nurseries it seldom if ever appears, but in others again it affects Tomatoes only when planted out, not those in pots. Its obscure character renders this complaint one of the most difficult to deal with, but I am inclined to attribute it chiefly to an excessive amount of iron in either the soil or the water employed. The disease known as mildew (*Cladysporium*) is also very destructive at times, generally appearing in July or August, particularly when the weather is damp and close. It is probable that if the Worthing growers provided their houses with better means of ventilation they would experience less trouble from this cause. The Potato disease, or "black stripe" as it is termed by some, also causes some amount of loss among all classes of growers. This is, as a rule, more common and destructive in a moist close season than at any other time, but even in a summer like this, when no rain to speak of has fallen for several months, I notice that a plant here and there becomes attacked. These are at once pulled out and burnt in order to prevent, as far as possible, the affliction spreading any further. Almost the only

#### FLOWERING PLANTS

that are cultivated in the Worthing nurseries are Chrysanthemums, Arum Lilies and Roses. These come in admirably as catch crops, and by bringing in money, more or less in dull or off times, with little or no extra expense or trouble, add materially to the profits. Chrysanthemums are principally grown in pots and housed and bloomed in vinerias and Tomato houses after the fruit is over. The climate is so mild, at any rate up to about Christmas, that little or no heat is required even for the late varieties. Those most commonly grown

are Lady Lawrence, W. H. Lincoln, Sunflower, Souree d'Or and to a smaller extent L. Canning (a grand late white), Mrs. G. Rundle, Mrs. Dixon and Mme. Desgrange. A few years ago late Chrysanthemums paid well, but lately the market has been so glutted with blooms even at Christmas that they have become a perfect drug, and scarcely saleable at any price the last season or two, and early varieties are now the more remunerative. Roses are forced in early vineries and Cucumber houses and often realise good prices. The plants are chiefly grown in large pots, which are turned out-of-doors as soon as the bloom is off, repotted some time during the summer and brought in again when the houses are started in the winter or early spring. The varieties chiefly grown are Catherine Mermet, an old variety very similar to this called Clothilde, of which, though not quite so fine, the blooms are much more abundantly produced. Niphetos and a few Perle des Jardins, &c., are also found in smaller numbers. Maréchal Niel is not much grown, as it is of no use as a pot plant, and the growers do not care to occupy their roof space with such things.

Arum Lilies succeed wonderfully here, and even under decidedly rough treatment produce a profusion of fine foliage and large blossoms almost continuously, but the price is now so low as to be scarcely remunerative. The double scarlet zonal Raspail again is grown in some nurseries for winter blooming with considerable success, but as a rule the plants are very roughly treated and do not get a chance to show their true character.

B. C. R.

#### CHERRIES.

The enormous crops of these that have been grown this season both on standards and walls will no doubt convince most people that a severe winter has little or no effect on most of our hardy fruit trees. Though some varieties that are somewhat tender and those growing in unfavourable situations may be injured by the frosts, those making firm wood do not often suffer much. Many were complaining that owing to the cold wet summer the wood could not ripen, therefore fruit would be scarce. This, however, is not the case, and with the exception of Plums and Damsons growing in the open, most of the hardy fruit trees are well laden. Cherries and Apples are the most abundant crops on record. The trees, too, of the former have not suffered so much from the attacks of aphides as in some seasons; on that account the foliage is clean and healthy, many of the varieties having produced fruit of good size and fine flavour. With me Early Rivers was the first to ripen its fruit, and though the spring was a late one, splendid dishes were gathered from trees on a south wall the second week in June. This fine early variety deserves to be better known, for the fruit is, in addition to its earliness, both large and of fine flavour. Adams's Crown was the next. This is a rather small, but highly flavoured variety of the Bigarreau class. Planted against a south wall it never fails to produce a crop, and being one of the first to bloom is very attractive in early spring. Bigarreau de Sebreken ought certainly to find a place in all gardens on account of its fine flavour. Black Tartarian was certainly never better than it has been this year; though the fruit is perhaps not quite so large, the crop is all that could be desired. To prolong its season I have it planted on various aspects, for on a hot south wall the fruit soon loses its flavour, while on one facing north or north-west it will often keep good till the middle of August. Frognore Bigarreau and Empress Eugénie were also very fine; while some of the later kinds, such as Reine Hortense, Florence, Bigarreau Napoleon, Bigarreau de Hedelfinger, have very fine crops that will with care give us a supply till the end of next month. It is generally thought that Cherries do not succeed well on a north wall, and this may be the case in the northern parts of the kingdom, but here they do very well indeed; in fact I have them planted on every aspect, where they grow most luxuriantly. Black Tartarian,

Elton, May Duke, Late Duke, Florence, Duchesse de Palluaux, Black Eagle, Empress Eugénie, Buttner's Black Heart, and Morello all succeed well when grown thus, and by so doing the season is extended by several days. I have never had Bigarreau Napoleon or Florence so fine as they have been this year, the fruit hanging in clusters all along the branches. Morellos, too, are very good, though I fear the fruit will not be so large as it usually is owing to the long spell of dry weather. Trees that are carrying heavy crops of fruit will be greatly benefited if a thorough soaking of liquid manure could be afforded them, or, failing this, some artificial food sprinkled over the surface and washed into the soil. It is not wise to encourage the trees to make a too sappy growth, but when the trees are carrying heavy crops of fruit they will need all the support that can be afforded them. Otherwise they will soon become sickly and fail to make sufficient wood to produce a crop of fruit. The foliage and fruit should have a thorough washing before it ripens, particularly that which it is intended should hang till the end of September, as this will rid the trees of any cobwebs or other dirt that may have accumulated. Netting the trees should be attended to at once, as birds are very troublesome this season. Wasps also are becoming very numerous, and if the present dry weather continues will be a source of much trouble to the fruit grower.

*Buxted Park, Uckfield.*

**Pruning Black Currants.**—The somewhat novel method of pruning Black Currants as described by "D. T. F.," p. 17, will not commend itself to all cultivators of this fruit. In some gardens Black Currants do not grow sufficiently fast to bear such drastic cutting down as suggested. We all know that Black Currants of the finest quality are produced upon the young and vigorous sucker-like growths that annually spring from the base of the bushes, but the difficulty is to get the trees so vigorous as to warrant all the fruiting branches being cut clean away yearly.

—E. M.

— I was pleased to see "D. T. F." (p. 17) advocating the early pruning of Black Currants, and though I have not advanced so far as his fellow juror in removing the branches with the fruit on, picking the fruit therefrom in a shed, I can fully recognise the advantages of doing so. For the past fifteen years I have pruned immediately the fruit has been all picked, cutting away most of the old wood that has borne a crop, and encouraged in every way the production of young wood or suckers from the base. During the whole of the period named I have never failed to have excellent crops of Black Currants and the berries of more than average size, that have been equally valuable for home use or market. Some time ago I went round a large fruit-growing place where Black Currants are admirably grown, and the manager attributed their success in a great measure to the annual removal of as much old fruiting wood as could be spared without unduly reducing the dimensions of the bushes. Many other instances could be quoted to prove the great value of early pruning, but, as "D. T. F." truly remarks, the single stem style of training is utterly unsuited for the production of young wood from the bottom. Another advantage of the system advocated is the reduced attack of the Black Currant mite. Such bushes are not only more vigorous and healthy, but the wood is so well matured that the insect appears somewhat loth to infest the buds. In all fruit-bearing trees we find those that are crowded with imperfectly ripened wood, and also weak, certain to become infested with hosts of enemies, whereas those full of strength escape in a great measure. In addition to the early removal of exhausted wood, I burn the same when the pruning is finished, returning the ashes to the soil, thus replacing to some extent the elements taken therefrom and preventing the accumulation of insects that are so apt to get into the heaps of prunings.—W. G. C.

## GARDEN FLORA.

### PLATE 1024.

#### SELF-COLOURED CINERARIAS.

(WITH A COLOURED PLATE.\*)

CINERARIAS remain, as they have for many years past, amongst the most popular of greenhouse plants. They are formal in no small degree, but the flowers are so splendid in colour, broad, full and massive, that we welcome them for the brilliant display created by a bold group in the late spring months.

The coloured plate represents three varieties selected from those in bloom last spring in the nursery of Mr. James at Farnham Royal. He has brought, by careful and successful hybridisation, the flower to great perfection, and the several houses of plants in full beauty are a picture we enjoy, because harsh and poor colours are rigidly eliminated. Only flowers are retained that give such beautiful self tones as those represented in the plate. One house will be filled with an intense crimson, another with royal blue, then pure white, and so on through a delightful series of shades, either purely self or set off by a margin of some distinct colour on a ground of white. Last spring one large house was filled with nothing but forms with flowers of shades of blue, some light, some dark, some entirely self, others again white, touched with perhaps a sky-blue shade or the reverse.

It is this purifying of the colours that deserves hearty encouragement, and we would wish that in other florists' flowers a sifting out of the magenta shades could be quickly accomplished rather than encouraging colours that spoil utterly what would be a charming race. Once get a family spoilt by a wretched muddy or unpleasantly harsh colour, and it is the work of years to drive out the dross. Visitors to the spring displays of the Royal Horticultural and Royal Botanic Societies will remember the groups from Farnham Royal, in which one gets a plant, dwarf perhaps almost to a fault, but sturdy, dense, with a wealth of robust foliage, almost hidden by a crown of blossom, packed well together, yet not hiding the true form of the individual flower, broad, massive, and not coarse. Size in this instance does not mean coarseness, but we rejoice in bold flowers of splendid and diversified colouring. Perhaps we may in time extend the flower colouring, at least there is room for other shades, and they will be welcomed if pleasing and a departure from those we are familiar with. We need say little more about the flowers seen in our coloured plate.

The culture of the Cineraria has been described so often in THE GARDEN, that it is a weary, because oft-repeated, task to travel over ground already well trodden, but we may mention that the plants at Farnham Royal are grown in low span-roofed houses provided with ample ventilation. It is possible by hybridisation to almost alter the entire character of a plant. Look at the modern Cineraria compared to the species from which the race has sprung—*C. cruenta*, introduced from the Canary Islands in 1777. This Cineraria is a beautiful plant, as the groups in the Royal Gardens, Kew, show, an informal, branching and charming plant growing several feet high and laden with soft purplish coloured flowers that stud the shoots like the stars of a Michaelmas Daisy. It only wants greenhouse treatment, and is worth growing not only

\* Drawn for THE GARDEN by H. G. Moon in Mr. James's nursery at Farnham Royal. Lithographed and printed by Guillaume Severeys.

for its telling effect in a mass, but for the value of the graceful bending sprays in the house. Another plant sometimes called *C. auita*, but correctly named *Senecio lanata*, is too much in the background. Its beauty is of a different kind to that of *C. cruenta*, but quite as precious. It blooms in the summer months, continuing for many weeks, and grows from 2 feet to 3 feet high, the leaves being conspicuous for the silvery down on the underside. The fragrant flower-heads are several inches across and composed of white ray petals charmingly tipped with bright purple, the disc of a purple shade also and forming a charming association. As each flower is  $1\frac{1}{2}$  inches broad, one can see that a plant in bloom is full of soft colour. Its culture is quite simple if cuttings are taken in May before the plant blooms, selecting the shoots at the base. Place them singly in pots  $2\frac{1}{2}$  inches in size and stand in a propagating frame. Pot on when rooted and thence onwards until 6-inch pots are reached, a size sufficiently large to produce good flowering specimens. Pinch the shoots once or twice to induce a bushy habit, and when the plants are in full growth give liquid manure. Like *C. cruenta*, this is also a native of the Canary Islands.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**FIGS IN POTS**—The trees which fruited early in the spring should now be thoroughly exposed to mature the wood, and thus prepare them for hard forcing. In advising exposure I do not mean that the pots should be exposed, as this will cause much drying and loss of roots. Plunging in larger pots or in soil is a good plan, the latter preferable, as less moisture is needed and the roots are kept quiet. In whatever way the plants are treated it is well to keep the surface roots active by a good mulch and ample moisture. Such kinds as Pingo de Mel, St. John's or other early varieties will have ceased to grow and will be showing the embryo fruits at the points of this year's wood and on spurs. These must be kept as quiet as possible, just damping over in the evening to keep the wood plump, and should scale have got a foothold, now is the best time to cleanse, using soapy tepid water and a soft brush, as when the fruits get larger they are easily injured. I am a great advocate for repotting just as the trees lose their leaves, and with early forced pot trees there is no better time to do this work than during the next few weeks, getting the compost prepared at an early date. If at all dry it can be turned frequently and watered. Such aids as bone meal, old mortar rubble and sound loam should be preferred to manure and light sandy soil. Plants that have become large and which it is difficult to give a larger shift to may be turned out, the drainage removed, strong roots cut away, and say 2 inches of the old ball removed with a pointed stick, cutting clean away some of the oldest roots, repotting firmly into the same sized pot, and damping freely overhead for a short time till new root action is active. Plants that do not need repotting should be top-dressed and treated as advised for plants just turned out to mature their growth. Young plants potted on should be shut up early, not allowed to carry fruit, and stopped when the new growth is from 4 inches to 6 inches long. If the pots are well filled with roots, liquid manure and top dressing will be beneficial.

**FIGS PLANTED OUT**—Trees in the earliest house will now have nearly perfected the second crop, and should not be allowed to carry more fruit, as if overcropped now, next season's first crop will be poor. Free exposure and thinning out of useless wood will now be all that are required, not omitting to freely syringe the trees in the evening. Maintain a free circulation of warmth in the pipes to assist in the ripening of the new wood, and do not

fail to remove fruits now showing, as these will not remain on the trees. The first crop for next season will greatly depend upon the new growth, which should be as hard and brown as possible. Now is a good time to cut away any useless wood and thus give that left free exposure. The roots should not be neglected, and if previous mulchings have been washed away give another now. In light soils I have found cow manure a splendid mulch at this season. If a dressing is given when the manure is partially dried and well watered afterwards, the surface roots soon go freely into it.

**LATER TREES** will now be furnishing a second crop of fruit and showing many more than is good for the trees. A large portion should be removed, especially those on the upper branches, and no time should be lost in doing the thinning to prevent the fruit being small. A genial temperature should be maintained, shutting up early and damping all parts of the house. Every opportunity should be taken to syringe the trees both above and below the trellis if the fruits are not ripe to prevent red spider doing mischief. With so much sunshine the crop is more advanced than usual, but I do not advise retarding, as the resting period is none too long, and only a good second crop should be taken. Late houses not forced should have plenty of air, and in sunless days or damp nights a little warmth in the pipes, at the same time giving air on the top ventilators. Thin the fruit freely, as also the wood, removing any late-formed fruits, as these will not ripen and will prevent the formation of good fruiting wood for next season.

**BANANAS** will at this season repay for extra attention in the way of plenty of rich food. Plants showing fruit should now be induced to throw up, as the fruits formed during the next few weeks will ripen next spring and be most acceptable. Plants likely to fruit should be kept cooler and not fed till they throw up. By giving a slight check the formation of the fruit is hastened, and liberal supplies of food may then be given in the form of liquid manure. Plants at what may be termed the successional stage should be kept moving, but not checked, gradually reducing the temperature as the days shorten. Should red spider be troublesome, sponge the leaves with soapy water, syringe freely, and maintain a moist growing temperature. Sucker growths from fruiting plants should be potted up when large enough.

**ORCHARD HOUSE**—Trees that have been cleared of fruit and have perfected their growth should now be removed to an open sunny quarter, plunging the pots, covering the surface with short litter or spent manure, and supplying the roots with plenty of water. A good syringing overhead in the evenings after hot sunshine will do much good and keep the new foliage clean and healthy. Late fruiting trees will be much benefited by mulching. The same remarks apply to earlier trees; if the mulch is spent or washed away it should be renewed and the trees given copious supplies of water both overhead and at the roots. Apples, Pears and Plums in pots require rich food. Thinning should be vigorously carried out, fine fruits being the chief points required in pot trees. Remove any growths shading the fruit.

**STRAWBERRIES IN POTS**—If the plants were layered as advised, no time should be lost in detaching them from the parent plants and placing for a few days under a tree or north wall where partial shade may be afforded them, watering overhead lightly two or three times daily to prevent flagging. Previous to potting up, no matter how the plants are secured, it is well to prepare a good heap of compost, selecting a good sound or retentive loam, and adding a liberal portion of old Mushroom bed manure with a sprinkling of bone-meal or wood ashes. Many good growers advise the use of soot, but care is required not to use it in large quantities, as the small tender roots are liable to suffer. I prefer to water later on with clear soot water. If soot is used it is best laid over the crocks under the layer of large pieces of soil usually placed in the pots when potting. The required number of pots should be got together, and if new, soaked for a

short time in a tank before using to prevent them absorbing moisture from the soil. Pot firmly, and in placing the small ball in the fruiting pot take care not to bruise the roots with the potting stick. Keep the collar of the plant just under the surface after the pot is filled, and in all cases leave plenty of space for water and food. After potting, stand the plants on a hard coal ash bottom, water sparingly till new roots reach the sides of the pots, and lightly dew overhead with the syringe in the afternoon when the sun declines.

G. WYTHES.

### THE KITCHEN GARDEN.

**GHERKINS**—These are still grown by some gardeners, and are most useful in autumn. They also come in well for pickling associated with other vegetables. If the plants were favoured with a sheltered situation and duly protected from cutting winds and late frosts, growth will now be vigorous. Do not allow many fruits to remain on the plants for the present, as there is yet plenty of time for a good long fruiting season before the plants are cut down by frost. Before more growth is made mulch well for some distance round the main stems with short manure, and give a soaking of farmyard liquid once in three weeks. Keep all weak and deformed laterals in the inside of the plant thinned out, and all small blooms removed as soon as they appear. If in an extra warm, dry situation, the foliage will be liable to the attacks of red spider, which if not destroyed quickly weakens and destroys the general vigour. To check it apply the hose or the garden engine once a week at even-tide, plying it as much as possible on the underside of the foliage.

**LATE VEGETABLE MARROWS**—Seed of this esteemed vegetable sown now will produce plants which, grown on with care, will yield fruit at a date when the bulk of the Pea and Bean crops is exhausted. Place the seed pots in a cool frame or greenhouse, and bring the plants on as hardy as possible. This will give them a wiry constitution, and one not easily affected by moderate frosts, should such occur in early autumn. As soon as the roots have well filled a  $4\frac{1}{2}$ -inch pot, transfer the plants to their final quarters, letting this be as warm and as sheltered as possible, and where rough protection can with ease be given as soon as the cool nights of October approach. For this batch there is no better variety than Pen-y-byd, as this is a short-jointed, moderate grower, and more easily protected by stakes and canvas or mats than are some of the more rampant growers. When planting always leave a small basin round each stem, so that the balls may be kept well moistened until the plants are well established and better able to take care of themselves. Although planted late, mulching will be advisable, as, provided there is ample drainage, Marrows cannot well be too moist at the roots.

**OLD SEAKALE BEDS**—Where these have been forced from year to year with pots and leaves the plants will, on account of early growth, now be covered with flower-stems. These must all be cut off, and if more side growths have emanated from the old stools since the thinning out advised some time ago was given, the whole of these also must be cut away. Now is the time to apply stimulants, either in the form of liquid of fair strength, or artificial manure sown broadcast and watered home.

**SPRING PARSLEY**—There is often a great scarcity of this commodity during March, April and May, and indeed until the spring-sown batches are fit for gathering. There is usually such a call for it for garnishing during the winter, that all full-grown plants, even if protected by frames and pits, get severely punished, these coming away into new growth slowly in spring. In order, therefore, to meet this emergency I always sow seed on a well-worked rich piece of land about July 20. This, if well looked after and duly thinned, will make capital strong stuff for standing the winter with frame protection. Sometimes it makes sufficient growth by autumn to

allow of a little being picked from it in winter, but it is not advisable to take away any but the very strongest fronds. In February this bed will rush into growth and furnish abundance of capital Parsley through the months above named. Earlier in the summer I advised the preparation of the plot for this crop, incorporating a fair quantity of gaslime and burnt earth, and if this was done, further precautions may be taken at sowing time by strewing wood-ashes in the drills after sowing the seed. Thin out the seedlings as soon as fit to handle, this being doubly important with Parsley that has to stand the winter.

**ENDIVE—MAIN CROP.**—I sow my main crop of broad-leaved Endive from July 15 to 20, selecting a somewhat cool moist border from which Potatoes or Peas have been cleared off. Sow broadcast, not in drills, using only a moderate quantity of seed and netting over at once, as chaffinches are very partial to Endive seed. Fraser's Improved Broad-leaved is about the best variety for winter and spring use, not being so liable to bolt as the ordinary strains of Batavian. Sow also Moss Curled for earlier use, this not keeping with any degree of certainty after the fogs of November and December set in. Another sowing of the Broad-leaved should be made at the end of the month. One of the chief points in the successful culture of this salad is early and liberal thinning of the seedlings and final transplanting into good rich land, with frequent after-waterings should the weather prove dry. For early use a percentage of the young plants of Moss Curled may be left at regular distances on the seed bed: these receiving no check will go away rapidly and be fit for use during October, being blanched by placing large slates over them. Endive always pays for extra good treatment, as if grown on poor shallow land it becomes tough and bitter, spoiling the salad bowl.

J. CRAWFORD.

## KITCHEN GARDEN.

### ENDIVE.

WHILE good Lettuce is forthcoming there is much less demand for Endive. If the former either fails or is only little better than green leaves it is then when the winter substitute is most appreciated, though for my own part I consider Lettuce and perfectly blanched Endive go remarkably well together, one improving the other. Green Curled, of which there are two or three forms more or less distinct, is usually grown for the earlier, the Broad-leaved Batavian being a little later in attaining its full size, though by far the more valuable type. The value of the latter fine Endive is scarcely appreciated by those in charge of small gardens, and for their especial benefit I would add that it can be grown to such perfection as to almost rival the most perfect Cos Lettuce that can be produced, and might with advantage be more largely eaten as grown, that is to say, without being cut up and without dressing.

Ground newly cleared of early and second early Potatoes ought, without much labour being expended on it, to be in excellent condition for a crop of Endive. The preference should be given to the higher well-drained positions, more especially in the colder low-lying districts, as it sometimes happens that a severe frost is experienced before the crop can be properly stored, and it is in the lower quarters of a garden that it is most felt. It is quite time too that a start was made, and if a batch of plants has been already raised, so much the better. In the latter case there should be no delaying transplanting till the plants have pressed against and spoilt each other, sturdy Endive moving in the hottest weather without experiencing a severe check. Supposing the ground has been levelled, trampled if very loose, and generally firmed

down, drills may be drawn 12 inches apart ready for the plants and, if need be, watered. Before drawing or raising the latter give the seed beds a good watering, and this will save more of the roots. For the earlier crops or those that are to attain their full size, a distance of 12 inches apart may be allowed from plant to plant, but rather less space is sufficient for the later crops. Water when planted, and if the weather keeps dry occasionally afterwards. Instead of wholly clearing a seed bed the better plan would be to thin out the plants to a distance of 6 inches apart each way, and without much further trouble a serviceable early supply of well-blanched Endive will be had. As the plants in the thinned seed-bed increase in size they press against each other, and in time the outer leaves effectually enclose the hearts, blanching taking place accordingly. I have cut a surprising quantity of really good Endive from seed-beds 12 feet by 8 feet, and it does not keep so very badly either if duly protected with a rough frame and mats.

If no seed has been sown, then there ought to be no further delay in getting some in. Seeing that there is now a fair amount of ground clear or which may be cleared of other crops, and also that transplanting acts as a check to the growth of the plants, the plan of sowing the seed where many of the plants are to remain should be adopted. Prepare the drills much as advised for planting, not omitting the important detail of giving enough water or liquid manure to well moisten them, then sow rather thinly, cover with fine dry soil or level over, and do not resort to watering till the plants resulting show signs of needing such assistance. Where the seedlings come up rather thickly thin out lightly and timely. When large enough to move, other rows may be planted with the thinnings, these affording a good succession, and, I need hardly add, any blanks in the rows should be filled up. Finally, leave the plants from 10 inches to 12 inches apart, the greater distance proving none too much where the soil suits Endive. In order to have a late supply, or plants that can be kept till the spring, sow more seed, principally of the Broad-leaved Batavian, during the first fortnight in August, and the transplanted or smaller plants, if located on a rather dry border, will stand a fair amount of frost, though they would naturally be safer in pits and frames. Those who already grow Endive extensively ought also to bear in mind that well-grown plants of the Broad-leaved Batavian are well worthy of being used as a vegetable, forming a very acceptable addition to the none too extended list of winter vegetables. Mere dribblets, however, are of little service, and enough ought to be planted now on good ground to fill a great rough frame or pit next autumn.

The earlier batches of Endive—or say any already established where they are to grow—will not generally require to be protected, as these should be ready for use during the latter half of September and onwards. Much in each and every case depends upon the blanching being perfect, and it must also be remembered that well-blanched produce does not keep long. Not till the plants are nearly or quite fully grown are they in the best condition for blanching, and this should be done a few at a time. The earliest in the open may be tied up Cos Lettuce fashion, the outer leaves well enclosing the hearts, and if wanted particularly quick, be further enclosed in inverted flower-pots with their drainage holes stopped. One good old plan is to plant the earlier Endive in rather deep drills, or such as might be drawn for Peas, and later on to lay boards, slates or tiles over the rows. Extra good beautifully blanched hearts

can be had by adopting the plan of gathering the outer leaves around the hearts, not unduly confining the latter, and then covering with benders and mats, this in preference to moulding them up. Nearly or quite fully-grown Endive is far from being hardy. A moderately severe frost will damage the tips of the leaves and a rather rapid spread of decay results. It cannot, therefore, be said to be safe after the third week in September, though in the more southern districts it is frequently left out unprotected weeks later. Transplanting is a simple matter, and there should be no undue delay in moving the plants to where they can be protected. Storing where fire-heat is given is a mistake, as this causes Endive to run to seed quickly. Hundreds of plants might be stored in rough frames and protected with shutters, mats or litter, and glazed pits or frames may be similarly utilised. So also might the fronts of Peach cases, houses and vineries, and when hard pressed I have stored a quantity of Endive in open-fronted sheds, extra protection in the shape of mats, old canvas and newspapers being afforded as often as need be in each instance. Too often the roots of newly-lifted plants are surrounded with poor, dry soil; whereas they ought to have the benefit of some rich moist soil. They will root strongly into this and the quality of the hearts be improved accordingly, those formed by plants dry at the roots proving tough and bitter in flavour. Select a dry time for moving the plants, and tie up each with a strip of raffia prior to lifting with a fork or spade. Save a fairly good ball of soil about the roots, and carry on handbarrows or in flat baskets rather than jolting wheelbarrows to their destination. They may be packed moderately closely together, making the soil firm about the roots, and the greater part have the ties loosened or wholly removed. Never let the soil become dry. It only remains to be added that, failing rough frames, large numbers of plants might be massed together on a warm border and there be protected with a framework of wood or benders supporting mats and such like. The Mushroom house and also warm, dark cellars are capital places for blanching Endive, batches of plants being transferred to these every week or so during the late autumn and winter months. Even in this case the plants should have their roots surrounded by moist, good soil. W.

**Cutting herbs.**—Before such things as Mint, Basil and summer Savory get too far advanced or lose much of their foliage it will be wise to cut a sufficient stock of each, and after exposing them in a dry vinery at rest for a week or ten days, to suspend them from the ceiling of a fruit or herb room; there will then be no fear of scarcity during the winter months. When harvesting is left till the autumn there is frequently in the case of those subjects named nothing but stalks left.—J. CRAWFORD.

**Salaty and Scorzoner.**—The protracted drought of early summer has caused some of the earlier sown rows of these two roots to run to seed, or has produced a growth that will ultimately do so. The value of secondary sowings will therefore be apparent, these not at present being past the thinning stage. Give plenty of room, mulch if possible, and soak with liquid manure. Large roots of good quality may sometimes be secured by sowing moderately early on a north border and feeding the plants at intervals. Thus shielded from the scorching sun, running to seed is less frequent.

**Latest French Beans.**—From sowings made as late as July 20 it is quite possible to get useful pickings, provided the site is a sheltered one and protection be given to the crop after the middle

of October. Sometimes several three-light frames can be spared at that date, but if not, posts, cross-rails, and mats or canvas are good substitutes. Sion House, Newington Wonder, and Sutton's Dwarf Forcing are all admirably adapted for this late sowing, being less vigorous and sappy than many of the taller varieties, and therefore less susceptible to injury from rough winds which often prevail in autumn. Allow each plant plenty of room, so as to ensure a stocky and robust growth, the only guarantee for productiveness at a season when days are shortening and sun heat is less abundant.

**Lettuce for autumn.**—A sowing may now be made of suitable sorts of Lettuce for hearting in during September and October. Daniels' Continuity and All the Year Round are the best sorts in the Cabbage section, Hicks' Hardy being a capital Cos variety. Where late Celery is grown, the Lettuce plants may, as soon as fit to handle, be put out in well-moistened, shallow drills on the ridges between the rows; they will then all be cut before the last portion of soil from the ridges is required for earthing up. The sowing for winter supply may be postponed until next month.

**Varieties of winter Spinach.**—Few vegetables were so valuable last winter as Spinach; indeed in some gardens it was the only green vegetable left after the severe frost. There is no gain whatever in sowing the old well-known Prickly variety, as in the early spring it bolts quickly. There is another form of Spinach known as Long Standing Prickly, but I do not think it is superior to the round-leaved varieties. I should say it is a selection from the old type, and is recommended for its long standing before running. The best winter Spinach I have grown is the Victoria, and last season I do not think fifty plants failed out of thousands. The Viroflay is another very fine type of winter Spinach, and a valuable addition to the list. It is by some thought to be identical with Victoria. The Long Standing Round is also very similar to the Victoria. The three varieties of round-leaved I have noticed may all be relied upon for winter sowing, and will be found a great gain on the older types both in hardiness and bearing.—G. W.

#### WINTER TURNIPS.

Those who had a good store of Turnips last winter were fortunate, as the green crops were so much injured by frost that Turnips made a useful addition to the meagre supply when sown specially for winter use. Now is a good time to take into consideration the winter crop. I usually make two sowings—one the last fortnight in July, another early in August. The roots from the latter sowing remain in the soil to supply green tops, and if necessary fresh roots early in the year. By sowing at the season named a hardy kind, such as Yellow Petrowski, Golden Ball, or Chirk Castle, good roots may be had. For storing, Veitch's Red Globe is, I think, the finest type of autumn Turnip grown, being solid, of splendid quality, and a good keeper. This variety sown now will be of just the size required for keeping through the winter, stored in a cool shed or cellar, with plenty of soil, sand, or ashes to keep the roots firm. The Red Globe is a white-fleshed variety, with a band of crimson round the top, and in shape much like the early Snowball. Turnips may often follow second early Potatoes, but should the ground be dry it is well to saturate the rows before sowing and afterwards. To get good flavour, quick growth is essential. To secure this I have found a small portion of bone meal mixed with wood ashes and placed in the bottom of the drills very effective. Wood ashes is a good fertiliser, and superior to large quantities of animal manure. Many persons object to the yellow-fleshed Turnips, such as those recommended for early spring use, when the winter store is exhausted, but it is an objection that may soon be removed, as the flavour is superior if the roots are well grown. In the north these yellow-fleshed kinds are much liked, and a white Turnip

would stand but a small chance against the golden section both for keeping and flavour. The Chirk Castle Blackstone is white-fleshed and as hardy as the yellow kinds, but inferior in quality.

In sowing winter Turnips it is well to give ample space, as the plants if too thick do not bulb freely. A space of 15 inches between the rows is none too much, and by giving the plants room, firmer and better keeping roots are secured. To keep these roots sound many shifts may be employed. A warm store soon causes the roots to grow out badly and shrivel. Turnips do well pitted like Potatoes, but they must be well thatched over to prevent wet going through the covering. Roots stored in this way are of much better flavour than when housed in a dry or warm place. Turnips to stand the winter should be sown on an open quarter, and be frequently dressed with soot in showery weather if slugs are troublesome. G. WYTHES.

#### PEAS.

So far as the tables of the rich are concerned, large Peas are each year becoming more and more unpopular. For ordinary Pea eaters and those who want to make the most of their land, it matters not how large the variety so long as it is tender, sweet and of good colour, but private gardeners having to study their employers' tastes will, it is evident, have to confine themselves for the most part to small and medium-sized Peas. Of course, all must grow the small round section for first early use, none of the larger sorts doing their work in anything like so short a time; and for following Chelsea Gem I think William I. is still the best, the new Oxonian, although doubtless a good Pea, not being in my opinion equal to that sterling variety. At one time I thought it a more continuous cropper, but after another trial under exactly the same conditions, I see no difference in that respect, and William I. is of far better colour—a great consideration in private gardens. That well-known Pea, Wordsley Wonder, is a capital variety, being all that can be desired both as regards cropping qualities, colour and flavour. It is of a most convenient height for amateurs and all who have difficulty in procuring tall Pea rods. Although, of course, the yield per single row is less from these medium growers than from the taller section, this deficiency is made up by allowing far less space than is practicable with tall Peas; or if ordinary room is left, Cauliflowers, Potatoes or Lettuces may be grown in the spaces. That grand old Pea, Laxton's Fillbasket, is still to be had true from various seedsmen, and I intend in future to grow plenty of it, as it would be hard to beat by any of the newer medium-sized Peas. The best crops of this delicious Pea I ever saw were grown on a lightish soil in shallow trenches, mulching and watering being practised as soon as the bloom appeared. This is, I think, the best method to follow in the culture of all the medium growing varieties, except on soils that are naturally very moist. Perhaps the very best all-round summer Pea is Criterion, it being the nearest approach to Ne Plus Ultra of any Pea we have, though not growing quite so tall. It may be sown for succession close on the heels of William I., and right on till the June sowings of Ne Plus Ultra, British Queen, and other late Peas are made, and although too tall for ordinary field culture, it would, I am certain, pay well in market gardens, even though stakes had to be used for its support. Veitch's Perfection must be included in the list of first-class Peas. True, it requires good culture, but this it well repays. Omega, another old Pea of somewhat short growth, may still be regarded as one of the very best from a quality point of view, and just

the very Pea for amateurs. It crops continually and well and possesses the richest flavour, while its deep green colour is very taking on the table. For this latter class of cultivators, perhaps the most useful Pea for extra late purposes is Walker's Perpetual Bearer. Its average height is 3 feet, quality first-rate for a late Pea, its great mildew-resisting powers adding greatly to its value. I had almost forgotten Autocrat. This new Pea will surely make its mark. Its drought-resisting powers on hot, dry soils are wonderful. It yields abundantly and over an exceptionally long period, the pods, which are of a dense green colour, filling slowly, which is of great advantage when sown with other sorts, a succession being thereby secured.

More might be added to the list, but the foregoing will be found to satisfy where large varieties are objected to. Raisers of medium-sized Peas may rest assured that such will in the future be almost exclusively grown in first-class private gardens. J. CRAWFORD.

**Cauliflower Pearl.**—I have this season fully proved the merits of this new Cauliflower. It is indispensable for following Walcheren, to which, in my opinion, it bears a very strong resemblance. Its habit is good, the young inside leaves folding well over and protecting the heads. It does not, like some varieties, come in too quickly when once the heads begin to form, and may, by timely covering with the outer leaves, be retarded for a considerable time. Altogether, I consider Pearl a valuable acquisition, which should be grown by everybody.—C.

**White Elephant Potato.**—For a few years after the introduction of White Elephant it was largely grown both by cottagers and private gardeners. Many of the latter, however, abandoned it on account of its liability to grow too large on good soils. Many cottagers still cling to it principally on account of its tremendous yielding powers. In this neighbourhood it seems to be a favourite, and large breadths of it may be easily picked out in allotments by the bold, handsome trusses of white flowers which characterise White Elephant. The slightly pinkish colour sometimes discernible in this Potato proves, I think, its relationship with Early Rose, and both these Potatoes, together with many others that are liable to eat soapy from good, rich land, become mealy and excellent if grown on comparatively poor soil.—C. H.

**Intermediate Lettuce.**—This is a distinct type suitable for such seasons as this when good solid Lettuces are difficult to obtain on account of their running so quickly. I recently saw this variety in splendid condition at Gunnersbury House, Mr. Hudson being much pleased with it. I was much surprised to see such a small firm Lettuce have so much heart. There is no waste whatever, as the outer leaves fold quite close, readily blanching all portions of the plant. In habit it is between the Cos and the Cabbage, and in colour it much resembles the old Bath Cos, the flavour excellent and superior to that of the loose, large growing type of Cos or Cabbage. I should think it would be a very good variety for frame culture for the autumn or early spring. I intend to give it a trial for this purpose.—G. WYTHES.

**Cottagers' exhibitions.**—When inspecting the various exhibits at one of these exhibitions the other day I could not help thinking what a mistake it was to hold such in the month of July. This is far too early in the year for the bulk of cottagers' produce. The only vegetables that are then well represented are Peas, Potatoes, Broad Beans and Tripoli Onions. Spring Onions have by that date only reached half their normal size, while the same may be said of Carrots, Parsnips and Beets. Beans of the French or runner section are either absent or very poorly represented, while a good display of Leeks, Celery and various other things is quite out of the question.

Cottagers who exhibit roots at this early date have often to spoil their beds in order to find a dozen of the best specimens it contains, and the same might be said of Potatoes. When the shows are held, say, at the end of September, far better all-round results attend them, and all Potatoes, except the latest varieties, may then be lifted and stored for future use, the best being selected for the show. As for fruit, Currants of all kinds, and even Gooseberries, if protected from birds will hang well till the later date and be the riper and better for it. I think it is a capital plan at these rural gatherings to include farmers' produce in the schedule, this making the show far more interesting and securing a larger number of visitors. This, of course, cannot be done during July or the early part of August.—J. C.

**Spinach.**—The crop of this vegetable resulting from the sowing advised a fortnight since must now be seen to, as although growing on a shady north border it may be none too moist at the roots, especially if another crop preceded it. Thin out the seedlings, well mulch with old Mushroom manure, and give a good soaking with farmyard liquid; this will probably carry it on to the gathering stage. This may appear troublesome, but unless this precaution is taken, Spinach is very apt to run to seed prematurely at this late date, even when growing on a north border. The next sowing should be at the beginning of August, choosing an east border; this will come in well at the close of September and throughout October. The winter sowings must be deterred until the third week in August and first week in September.

**Pea Hundredfold.**—About twenty years ago this Pea was much in favour, and I never saw heavier crops than were grown by a friend who relied to a great extent on this variety. I lately saw it growing side by side with Fortyfold, Duke of Albany and other standard kinds, and it seemed to be yielding more abundantly than any of them. I remember once seeing some rows of this Pea grown on rather heavy loam, and looking down the rows there seemed to be more pods than leaves. Fortyfold is, in spite of the numerous varieties that one can now choose from, one of the surest cropping Peas, and seems to be well adapted for culture on light soils. In this district some still grow the Pea that was once widely known as Jeyes' Conqueror, but which does not seem to differ appreciably from Ne Plus Ultra.—J. C. B.

**Radishes.**—Radishes cannot be grown at this season of the year without special pains being taken, as in sunny positions and in ordinary soil they become hot and stringy even in spite of regular waterings. A north border is the best position, and the ground must be prepared by the addition of burnt refuse, potting shed soil and a portion of old Mushroom manure; this should be well worked into the border and a good soaking given, the seed being sown a day or two after. Even in this cool aspect watering must not be neglected, and free thinning of the crop must be practised as soon as the plants can be handled. The quick-growing Olive-shaped sorts are the best for this date, and a sowing every three weeks will be advisable where a constant supply is expected.—N.

**Watering Carrots.**—I have heard that watering Onions will induce an attack of the fly, and I have now come to the conclusion there may be some ground for such a belief. I was lately shown two lots of Carrots one of which had been well watered, the other remaining dry through the past dry weather. The watered ones were immediately attacked by grubs and were totally ruined. Every Carrot was eaten away at the point, and on opening a root a little white maggot was found in it. This is very different from the brown grub that attacks the roots near the surface. This can be checked by hand-picking, but in the case of the maggot above mentioned it is impossible to get rid of it in that way. It was curious to note that the plants that had remained dry had not in the least suffered, and yet they were growing within a few feet of those that were totally destroyed.—J. C. B.

### ARRANGING CUT FLOWERS.

For arranging cut flowers in a bold and natural way large simple glasses or bowls are the best. We have mechanical inventions wherein to arrange cut blooms, so that, as we are told, each leaf and flower can show its individuality, but fine flowers can only be enjoyed when simply arranged much as they grow in the open air. The illustration of sprays of the common white Jessamine will convey our meaning far better than words. During the greater part of the year there should be no scarcity of cut flowers, and when we can cut bunches of Roses, Carnations, and Irises, these surely should suffice of themselves, care being taken in every case if possible to use their own foliage as a foil. When arranged loosely, as in the case of the Jessamine, the quantity required is far less, while the effect is heightened in every way. By filling each bowl or vase with one thing, we can, when the flowers

shade. It is curious that, whilst scarlet and crimson selfs were abundant, every yellow kind sent out was thickly spotted or streaked with red. The flowers of the variety under notice are of a most delightful shade of pure canary-yellow, the flowers being of fine size with good broad petals.

### WORCESTERSHIRE ORCHARDS.\*

WORCESTERSHIRE orchards have long been famous in the annals of this country, for although records are fragmentary and incomplete, it is fairly certain orchards have existed and flourished in this county for a very long period.

In the year 1633 we find Gerard writing upon fruit trees and existing orchards, and he states what was at that time considered the proper functions of the orchard, viz., for the production of eider and perry. He particularly mentions a certain Master Bodonome, who lived on the borders, but in a neighbouring county, "who cultivated so many Apples and Pears that no other drink was

Flowers of the white Jessamine in a vase. From a photograph sent by Miss Marker, Combe, Honiton.

fade, clear them out and replace with others of a different form.

At the shows prizes are often offered for the best arranged epergne of flowers for table decoration, and although the arrangement may appear effective when done, the labour required is very great. Prizes for such arrangements only foster a false taste and give no idea of the beauty of flowers boldly used in a cut state, and cannot be accepted as examples of how they are to be arranged in the house, as they often associate badly, their lasting properties, too, varying considerably and necessitating much touching up to keep them in a presentable condition. An arrangement which we lately saw was very pleasing, and consisted of the common Cornflower cut with long stalks and arranged with the airy *Gypsophila paniculata*.

**Canna Miss Elsie Perkins.**—At the Cheshunt Nurseries the new *Gladiolus*-flowered Cannas are largely grown, and Mr. G. Paul has raised several very good kinds. That which bears the above name is distinct and charming in colour. There are now so many named varieties that the number is confusing, but one cannot question the wisdom of naming this kind, which gives us what was wanted, a pure yellow self free from spots of any other

used beyond that made from these fruits. Moreover, the quantity made was so great that the parson had for tithe many hogsheads thereof."

Gerard further enjoins landowners of that day to "go forward in the name of God, to graft, set, plant and nourish up trees in every corner of your ground. The labour is small, the cost little, the commodity is great. Your fellows shall have plenty, the poor shall have somewhat in time of want to relieve their necessities, and God shall reward your good minds and diligence."

It is quite possible that the few patriarchal old trees yet to be seen (Pears especially) are the surviving relics of this logical advice. Mention is also made of Pear orchards in the time of Henry V. At Agincourt, also, the men of Worcestershire (according to Drayton) had for their device upon their banners a Pear tree laden with its fruit. Again, there is that famous old variety of Pear, the Black Pear of Worcestershire—although seldom met with nowadays, said by tradition to be the Pear represented on the city arms—the date of which is uncertain, but in all probability coincides with that of the visit of Queen Elizabeth to Worcester. It is also beyond dispute that orchards flourished in conjunction with the monasteries, for we read that the monks

\* Paper read at Worcester Shire Hall before a conference of fruit growers of the county of Worcester.

had a special object in establishing themselves in situations favourable to fruit growing.

Enough has been said to prove how Worcestershire orchards flourished in bygone days; therefore it will be more interesting for this conference to trace out

#### THE CAUSE OF THE DECLINE

as well as to suggest a remedy. Two hundred years ago it was the necessities of isolation that caused orchards to be looked at as a source of profit by the manufacture of cider and perry, but to-day it is a world-wide competition that makes a similar demand. Thus it happens by a curious revolution in the cycle of commerce that the careful and skilful cultivation of our orchards has again become a necessity, and every effort must be made to improve the condition and to make them, as undoubtedly they can be made by proper application of skill and industry, one of the main sources of profit from the land. Orchards in those days were in the hands of the ordinary farmers, and it is more than probable that the decline of fruit growing arose partly from the prosperity of the country, and partly owing to a vexatious tax upon the beverages, combined with the introduction of cheap foreign but unwholesome wines. Agriculture was then prosperous, and it became more profitable to produce corn and cattle; consequently knowledge of orchard cultivation diminished and was neglected, whilst practical experience completely died out, facts which will take a generation to restore, for certain it is that at the present day there can scarcely be found a single workman whose employment is chiefly agricultural who possesses the slightest rudimentary knowledge of the requirements of a fruit tree's roots or branches. With a few exceptions, practical, sound knowledge is very little advanced in the ordinary farmer, and, as a rule, he belongs to rather a difficult class to instruct, as he does not take kindly to fruit growing. Whilst on this treacherous and divided part of my subject, I feel convinced that very great injury is frequently done to fruit growing by men who call themselves gardeners and represent themselves qualified to give advice and to undertake the management of fruit trees, but whose real knowledge of planting, pruning, the nature of soils, the selection of varieties and the many other details necessary is about as remote as the North Pole. It will thus be plain that before we can restore the prosperity of our orchards, able to produce with a certainty (occasional bad seasons excepted) immense quantities of fruit of the highest standard of excellence, fit to compete openly with our foreign rivals, very considerable knowledge will have to be extended to occupiers of the land. The increasing demands for fresh fruit from the growing populations of our large towns and the great discoveries of the present century have completely revolutionised all former experience. The forces of steam and electricity by land and sea enable space to be overcome by rapidity in transit, and lessen expenditure by gain on time and cheapness of conveyance, opening out wider markets for all articles of trade. We have to meet a world-wide competition in which, according to the inevitable laws of Nature, the best and cheapest must prevail. The benefit to the community at large is unquestionable, but to class interests and localities the results are sometimes disastrous. Agriculture, we know, is now sorely tried to contend with these changes, and the struggle increases in intensity. The result cannot be otherwise than to compel every district to produce those articles for which it is specially adapted in the very best possible form by the very highest system of cultivation. If free trade in corn, with its free freight and indirect bounty and the introduction of foreign live and dead meat, make the home production of these articles unprofitable and ruinous to the agriculturist, then why should not those living in the districts in every way suitable for fruit growing, as Worcestershire undoubtedly is, expend their capital upon orchard planting? In order to be a financial success this must be done in no half-hearted way. I wish to see capitalists

with sufficient enterprise planting their 50 acres of Cox's Orange Pippin, another 50 of Lord Suffield, another 50 of Dumelow's Seedling and so on. In conjunction with Apples, Pears, and Plums, Cherries, Strawberries, Raspberries, Currants, Gooseberries, &c., should be planted and the whole of the land attempted given over to fruit growing. For a county like Worcester to import foreign Apples is considerably worse than carrying coals to Newcastle, and I repeat that it is a standing disgrace to county fruit growers to quietly stand by and see the in every way inferior (colour excepted) American Baldwins and other kinds of Apples that have travelled thousands of miles by road and sea sold at our very doors for 3d. or 4d. per lb., whilst our own home orchards remain in the most deplorable plight. To continue grumbling at this sad state of things, and to wait for protection or some other salvator to turn up, is unworthy of true British pluck and indomitable enterprise. There can be no mistake, fruit growing is not played out and will pay, if set about in a proper skilful manner, but depend upon it the only way to beat the foreigner is to put better fruit than his on the market. I willingly admit France and the Channel Islands with their superior climate will always beat us for Pears; still even this is not hopeless; but as regards all our soft fruits we have nothing to fear from the importations except jam, which in time will right itself by legislation. There is also the cider and perry industry: properly manufactured on improved scientific lines both wholesome and good as well as economising the use of the small or inferior fruit, would assist the financial resources of the orchard. In order to compare the style of

#### FOREIGN FRUIT GROWING

with our own, I would mention the experience of a friend whose business relations have taken him through the United States and Canada annually for the last eighteen years. He says, "Twenty years ago a fruit orchard of 50 acres was then a wonder, but now in numerous States Apple, Pear and Peach orchards, 100 acres, 200 acres and 300 acres in extent, are common enough, and planting continues. In the State of Colorado, for instance, the first Apple tree was planted in 1863; now there are 30,000 acres in full bearing." He instances one planter who has 80 acres of Bartlett Pears—a Pear similar to our William's, the most risky and treacherous of all Pears as regards its ripening and early decay. Evidently there is a demand for this Pear somewhere. My quondam friend further assures me that systematical cultivation worthy the name is carried out there thoroughly, as taught by practical experience; also considerable knowledge in the early application of insecticides and fungicides to the trees, by spraying or washing. The fruit is honestly graded and carefully packed, with the grower's brand upon each package. Possibly there may be slight advantages in climate, virgin soil, &c., but if we contrast all this with the system pursued in our own Worcestershire orchards, we shall have little difficulty in arriving at the conclusion why foreign Apples are so often preferred to home-grown ones.

There is an old saying that "comparisons are odious," and I feel sure that the truth of that old saying will be realised and exposed if I venture to describe the

#### CONDITION OF OUR ORCHARDS.

Some farmers think they have done everything when they have planted the trees—stuffed the roots into small holes would be the proper description—they do not imagine there is any art in fruit cultivation, pruning, dealing with insects, grading or packing. Frequently the trees are unskilfully staked and injured by wind chafing. Cattle, rabbits and other depredators obtain access to the trees, and irreparable damage is often done. What few trees survive such reprehensible treatment in time become profitless examples of bad usage, and demonstrate as clearly as possible how not to do it, whilst as regards our older

orchards nearly every tree is a living picture of sheer neglect. Its branches are a thicket of dead and decaying wood, languishing from want of light by a little systematic thinning out and attention. The trunks and limbs are overgrown with Moss and Lichen, becoming practically the undisturbed breeding quarters of mischievous insects, which in due season sally forth in myriads to make raids upon all trees in the land, whether belonging to the careful or to the careless cultivator alike—a very bitter experience to some of us. It will be found that in the struggle for life these wretched old trees occasionally bear a few specked and ill-conditioned fruit at the extremities of their branches, which are generally sold for a lump sum as they stand on the trees to some promiscuous fruit dealer, who, of course, has no scruples for the trees at gathering time, for he roughly shakes them or beats the Apples off, collects them into pot hampers, and rushes them into market—good, bad and indifferent, bruised or unbruised alike—there to represent Worcestershire orchard-grown fruit, whilst the price realised is pointed out to us by our pessimistic friends as the unprofitableness of fruit growing. It is but a very few years ago since the growers of Grapes for market were in a similar predicament to Apple growers of the present day. The Channel Islanders then monopolised the Grape market, very much the same as the Yankees and colonials now do the Apple market, and very much to their own advantage, no doubt; but here, again, necessity became the mother of invention, for it was discovered by shrewd, practical men with brains and possessing true British enterprise that equal or superior Grapes could be produced in prodigious quantities with the help of cheap glass-houses close to the world's market, without the disadvantages of long transit by road and sea, at a cost that completely placed the foreigner *hors de combat*. It remains to be proved why we cannot repeat the process (less the glass houses) as regards the foreign Apple trade, at all events for a large portion of the year. I firmly believe we shall do so ultimately, but we have to first take decided steps by placing our orchards in a position capable of producing first-class fruit; the climate and soil will do that, provided the necessary skill and capital are forthcoming. There are men constantly telling us fruit growing will not pay until the land each man holds or occupies must be as good as his own; but surely at the present time there is no difficulty in that direction, for seeing the many acres of land going out of cultivation, much of which would be suitable for fruit growing, landlords would gladly encourage the object and be very glad to give the necessary security of tenure with all the advantages of recent legislation, such as small holdings, compensation for unexhausted improvements, and the like; indeed, in some cases they are prepared to supply trees gratuitously to competent tenants at fair rents. This system of gratuitous distribution of trees has been in operation on the Madresfield estate for about twelve years, by means of a home nursery set apart for this special purpose, and upwards of 1000 trees have been dispensed annually. The results so far have been very fluctuating, generally in accordance with the capabilities of the recipient; here and there splendid samples of orchard fruit have been and are now produced, and the trees well cared for, but in the greater number of cases opposite results are noticeable, and discouraging too. Of course, it is only well-proved varieties that are distributed, whether new or old, whilst my own modesty prevents me saying more than to simply mention that the few specimens I have to-day staged in this hall are fair samples of fruit grown under ordinary cultivation on bush trees, and not taken from trees set apart for show purposes, which sometimes spend part of their time under glass, showing for competition being prohibited at Madresfield. I have already pointed out that before we can succeed, as we all desire, we must first improve our methods of cultivation; therefore I presume it will be expected of me to give some description

how this can best be accomplished and what kinds of trees I consider best adapted for that purpose. There can be no doubt that the old-fashioned standard is capable of producing perhaps the greatest quantity of fruit, but, on the other hand, the fruit produced is certainly inferior in quality, size and appearance to that given by the more easily managed dwarf, or loose, open, bush kind of tree; by this, and to be explicit, I do not mean the little pigmy bushes grafted on Paradise or other dwarfing stocks, but the large, open, bush form trees on free stocks that have been carefully prepared in their youthful days, and now possess an abundance of healthy fibrous roots that work and feed near the surface, whose branches are each a perfect cordon of fruiting wood throughout, from the stem of the tree right out to the extremity of each branch. Surely we must admit each tree is worthy of the ground it occupies, although I fear many of us act differently, and I never could see the object of sticking our trees up on stilts, as it were, whereas better results could be obtained, greater access and convenience gained in pruning, spraying, gathering or thinning, and the numerous other attentions necessary would be facilitated without the stilts. Moreover, the aforesaid fibrous roots' requirements could be better dealt with, the necessary manures or plant foods could be more efficiently applied, and with the absolute certainty that the right parties appropriated it. The land for at least the diameter of the tree's branches should, therefore, always be held sacred to the roots, for we have no right to try for or to expect Grass or other crop upon this space. Curiously, it seems to be generally overlooked that attention to the roots is equal or of more importance than the branches, and it is this encouragement of this network of fibrous close-to-surface roots that demands our most earnest consideration, for, depend upon it, unless properly cared for, the trees cannot ripen their wood and perfectly develop their embryo fruit buds for next year's service. This failure to ripen up in the autumn is aggravated by the absence of sunshine during the summer, and is usually followed by the imperfectly formed flowers in the next spring, wholesale dropping off occurs and the inevitable failure of crop. It will, therefore, be conceded this most important detail cannot be too strongly impressed. Trees of this character may be planted at from 6 feet to 8 feet apart, or more, and alternate trees removed to a fresh plantation later on, for trees with good fibrous roots are always fruitful and can be easily removed with perfect safety and comparatively little check. We do not increase the area nor gain any other advantage by the old and, I hope, obsolete system of perching our trees on stilts, and I conscientiously maintain that an acre of before-described bush trees will give far and away better results than the old-fashioned standards; moreover, they fruit earlier and are better from every point of view.

I am hopeful, nay, sanguine, that the millennium of all this is in the near future, that is, when the small holdings become more perfect and general, such orchards will rise and spring up like Mushroom, which if combined with large depôts for the distribution of the produce and conducted on joint stock principles, or an extended system of co operation, where a quantity of these plodding small growers could concentrate and husband their resources, so as to place their products with a degree of certainty and reliability constantly within touch of the public requirements of the day. These depôts, or under-ground cellars, being best for storing, should be arranged for as near as practicable to competitive railways, for obvious reasons, with a central office in London or elsewhere, thus in direct communication with all retailers of fruit, and ready to supply 1 cwt. or 100 tons of any special variety of hardy fruit to order. To further speculate upon the all-round advantages of such a system and the huge home industry it would create would, I fear, be encroaching upon matters which will, I trust, be far more ably dealt with by the writers of other papers promised at this conference. Nothing has yet been men-

tioned as to the properties of soils, situations, shelter, natural drainage or otherwise, which are most suitable for the various crops of fruit attempted, all questions of supreme importance to the cultivator, but I fear my paper is already too long to allow me to enter into detail.

Take care that the land is clean, in good heart and deeply cultivated before planting, for land that has been sub-soiled and deeply ploughed or trenched, if spade husbandry is pursued, has the advantage of becoming warmer by atmospheric influences of sun and air. The rain also finds its way more readily into Nature's storehouse, there held in suspension, ready to be drawn upon in times of drought. If possible choose a site other than a low valley, for although the best soils are usually found there, fatal spring frosts are worst in such positions. Shelter from high winds has obvious advantages, but is of less importance. Let the trees be clean, healthy and good, avoiding those which have been grown thickly together in rows, consequently cheap, and do not lose sight of the fact that it is good, all-round trees only that produce good, clean, well-coloured and large-sized fruit fit to compete openly with and, I sincerely hope, ultimately oust the foreign importations by the next generation probably. Anyhow, the wish is father to the thought, personally, and it is an encouraging sign of the times (for which we are all very grateful) to see the subject appreciated and helped on by the County Council, through the horticultural section of technical education; whilst I sincerely hope both they and this conference of fruit growers may ultimately feel amply justified by results, direct or indirect, actions not words, of this their first meeting, thereby becoming a great power in restoring the balance of our agricultural population by opening out a new industry on a large scale, and if this is accomplished (as I predict it will be) no one will rejoice more than myself to see fruit culture extended and our Worcestershire orchards permanently improved.

## ROSE GARDEN.

### ROSES AT BATH.

THE Rose nurseries of Messrs. Cooling are situated on a pleasant slope not far out of Bath, and though not so extensive as those about Colchester, they are well worth a visit, especially from those who grow or love to see the Rose in all its varied types of beauty. The garden or nursery that only contains show Roses represents but one class of flower, but we are pleased to see abundant evidence of the growing popularity of those that are termed garden Roses, varieties whose charms are great. A host of these old and new kinds and, in fact, all that are worth growing find a home in these nurseries and there is a growing demand for them. It is strange that they should ever have been neglected, since no cultural skill is required to bring them to perfection, and in their season no flowering shrub can compare with them in sweetness and gay display of colour. Unfortunately, our visit was too late to enable us to see the picture they must have made but a short time previously, for there were Roses of all ages, kinds and sizes, from the little De Meaux and Spong up to great bushy pyramids of such strong growers as Mme. d'Arlay and Félicité-Perfète. Some, however, were still in full bloom and demanding notice. Among these is Mme. Alfred Carrière, a Rose by no means new, but one that for some reason has not found many admirers. It is a robust

growing, making a huge bush or covering a wall rapidly, and flowering long and abundantly, the blooms pale flesh and deliciously scented. Bardon Job would make a brilliant group in the garden, the plants bearing a long succession of crimson buds and blooms.

A very charming single scarlet Rose raised by Messrs. Cooling will shortly be sent out, named Glare of the Garden. It has the habit of growth of the Hybrid Perpetuals, free and robust, not climbing in habit, though doubtless with age it would grow into a large bush. The flowers are quite single, very large, borne in clusters, and of a glowing crimson colour. The new Sweet Briers are largely grown here, but Mr. Cooling thinks, as many more do, that there are far too many of them with distinctive names, although Lady Penzance is a welcome acquisition for its distinct colour. Janet's Pride, one of the older kinds, is also good, and we saw immense bushes of it. Mme. Trochon, very pretty here, with white buds in clusters, might be described as a white W. A. Richardson. Mme. Pernet-Ducher, Mme. Pierre Cochet, and Gustave Regis, all recent varieties of the most free-flowering character, are bound to become popular garden Roses of the future. The good and sweet old Celine Forestier we saw in quantity. Two varieties that the year has favoured and which were covered with many tinted flowers are Jaune Desprez and Ophir. We have so many really first-rate Roses as free as these two kinds and more to be depended upon in the average season, that they have not the value they once had and, if dispensed with, would scarcely be missed.

Two new Roses raised here impressed us much more favourably than when we saw them at the Crystal Palace recently, especially that named Bladud. A row of plants of this variety was very striking, every shoot standing erect, crowned with a large flower of wonderful substance. Although extra full and double, the flowers have expanded well; they are of globular form, high in the centre, bluish-white in colour. The other variety, named Lawrence Allen, is equally free and robust, its flowers full, large, and of a light pink colour. The heat and drought have suited certain Roses, and among these is Horace Vernet, which had numbers of perfect richly-coloured flowers. A. K. Williams, Ulrich Brunner and Mrs. John Laing were also in fine form.

### TEA ROSES

were numerous in all the best varieties. A recent variety, Beauté Inconstante, was specially good, most distinct and charming in colour, but essentially a garden Rose, the flowers of that peculiar indescribable copper-yellow and bronzy red hue that attracts notice by reason of its novelty as well as its striking beauty. Adrienne Christophle rejoicing in the sunshine bore flowers of the brightest hues characteristic of this many-tinted Rose; great blooms of Jean Ducher were conspicuous; whilst Ethel Brownlow and Mme. Cusin were certainly brighter and better for the tropical sun that had brought them out. The dry summer following the severe cold has had a fatal effect upon stocks for this year's budding in many places. Messrs. Cooling are fortunate, however, in possessing the best lot we have seen anywhere this season, and the reason is not far to seek, for what at the time threatened to be a grave disaster has doubtless been a blessing. Bath suffered greatly from last winter's floods, and the stock quarters were inundated with water several feet deep. This left the ground so saturated, that water has not been so essential as it would otherwise have been.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 23.

THE meeting on Tuesday last was an interesting one although the exhibits were fewer, considerably less space being occupied than for some time past. Orchids showed the greatest falling off, but hardy flowers were well represented, and Sweet Peas in three comprehensive groups were a feature in themselves. Among fruits, Gooseberries largely predominated, grand Madresfield Court Grapes were shown, and the large exhibit of Duke of York Tomato testified to the high merits of this new variety.

Orchid Committee.

First-class certificates were awarded to the following:—

PHALENOPSIS LUDDE-VIOLACEA, a hybrid raised by Mr. Seden from *P. Luddemanniana* × *P. violacea*. The plant had six strong leaves and partook more of the habit of *P. Luddemanniana* than the other parent. The flower also resembled that of *P. Luddemanniana* to a great extent, the sepals and petals rose-purple barred with a darker shade; lip dark crimson with a yellow disc. From Messrs. Veitch and Sons.

LÆLIA (BRASSAVOLA) DIGBYANA.—An old and well-known plant, but no record exists in the society's list of its having been previously certificated. The sepals and petals are greenish yellow, lip of the same colour, having a heavy woolly fringe in front.

Awards of merit were adjudged to the following:—

DENDROBIUM SPECIOSISSIMUM.—This species was awarded a botanical certificate at the previous meeting, but being shown now in better condition it received the above award. In habit of growth and in the shape of the flowers it resembles *D. Jamesianum*, the sepals and petals pure white, lip white with a yellow disc, changing to pink in the throat. From Messrs. F. Sander and Co. and Messrs. Hugh Low and Co.

ANGRÆCUM EICHLERIANUM.—A distinct and beautiful addition to the genus; sepals and petals each  $1\frac{1}{2}$  inches long, pale green; lip white in front, with a pea-green centre. From Messrs. F. Sander and Co.

DENDROBIUM PORPHYROGASTRUM.—A hybrid between *D. Dalhousianum* and *D. Huttoni*; sepals and petals lilac, veined with a darker shade; lip rose-lilac in front, with a large dark purple disc. From Messrs. Veitch and Sons.

Botanical certificates were awarded to—

Mormodes pardinum, an old well-known species, with yellow flowers, thickly spotted with brown. From Mr. F. W. Moore, Botanic Gardens, Glasnevin. Maxillaria Hubschi, a distinct species, sepals and petals white, tipped with purple, lip yellow in front, side lobes brownish purple. From Mr. F. W. Moore. Habenaria rhodocheila, a new species, sepals and petals green, lip vermilion-scarlet; a distinct and beautiful addition. From Sir T. Lawrence, Bart. Eria latibractea, a distinct form of this somewhat despised genus, with creamy yellow sepals and petals, lip yellow, with brown side lobes. From Messrs. Sander and Co.

Messrs. T. Cripps and Sons, Tunbridge Wells, exhibited a fine group of *Disa grandiflora*, finely grown and well flowered. A silver Banksian medal was awarded. Messrs. Hugh Low and Co. sent a group, prominent among which were *Cattleya Leopoldi* in variety, *C. Rex*, *C. Schofieldiana*, several plants of *C. Eldorado*, a fine variety of *C. Warszewiczii*, *Lælia tenebrosa*, *L. Cattleya elegans*, *Dendrobium speciosissimum*, *Cypripedium Curtisi*, *C. callosum*, *C. javanicum-superbum*, said to have been imported with *C. callosum*, and *Lycaste Rossiana*. Messrs. F. Sander and Co. showed a small, but effectively arranged group, comprising *Dendrobium Phalaenopsis* in variety, *Stanhopea Mastersii*, *Cypripedium Aspasia* and the supposed natural hybrid *C. Kimballianum*, *Cirrho-*

*petalum picturatum*, a large mass, carrying seven fine spikes of flower, *Brassia Lewisi*, *Dendrobium bracteosum* and its variety *album*, *Grammatophyllum Measuresianum*, a fine dark-spotted variety, *Cattleya Gaskelliana* (Cook's variety), with pale rose-coloured flowers, *C. Warszewiczii* in variety, a fine dark variety of *Sobralia xantholeuca*, *Odontoglossum biconense album*, *O. purum*, *Miltonia vexillaria*, and *Batemannia Burtii*. Messrs. Veitch and Sons exhibited *Dendrobium glomeratum* and a very fine variety of *Miltonia vexillaria superba*. Sir T. Lawrence, Bart., Burford, Dorset, sent *Epidendrum alatum*. Mr. W. C. Parkes, Lower Tooting, sent a cut spike of *Cattleya Warszewiczii* carrying five large flowers. Mr. R. I. Measures sent *Maxillaria ochroleuca*, *Bulbophyllum Sanderianum*, and a three-flowered spike of *Cypripedium Godefroye*. Mr. J. Foster Alcock sent *Lælio-Cattleya elegans Schilleriana*. Mr. F. Hardy exhibited a fine made-up specimen of *Miltonia vexillaria superba*, also *M. v. rubella* and *Cypripedium leucochilum* var. Mr. J. Gabriel, Streatham, sent a four-flowered spike of *Cattleya Rex*. Mr. Walter C. Walker, Winchmore Hill, sent a well-grown plant of *Cypripedium Godefroye* carrying six flowers. Mr. F. W. Moore sent *Epidendrum paniculatum*, a fine variety of *Bulbophyllum Lobbi*, and *Aerides Lobbi*. Mr. E. H. Woodall sent *Lælia crispa superba*, a cut spike with two fine flowers. Mr. A. Witt, Maida Vale, sent a *Dendrobium* species in the way of *D. clavatum*.

Floral Committee.

First-class certificates were granted to the following:—

CAMPANULA VIBALI.—A shrubby greenhouse species and an old garden plant, but never probably seen so well grown and flowered as were the plants shown. From Mr. J. T. Bennett-Poë, Holmwood, Cheshunt.

DAVALLIA TENUIFOLIA BURKEL.—This is a recent introduction from New Guinea, and will make a lovely stove Fern for growing in baskets or in any position that will show off its graceful drooping fronds, which are long, of a light green and hang down most gracefully, even when the plants are young and small. Shown by Messrs. J. Veitch and Sons, Chelsea.

LILIUM JAPONICUM COLCHESTERI.—This is the true *Lilium odorum*, and differs appreciably from *L. Browni*, which is too often substituted for it. It is a grand Lily with a delicious scent. A note pointing out how these two kinds differ appears on another page. From Messrs. R. Wallace and Co., Colchester.

NYMPHÆA MARIACEA CHROMATELLA.—This is the first of *M. Mariacæ*'s fine series of hardy hybrid Water Lilies, and is now tolerably well known to our readers, as a coloured plate of it was given in THE GARDEN as far back as March 31, 1888. Shown by Messrs. Veitch.

Awards of merit were granted to the following:—

NYMPHÆA LAYDEKERI ROSEA.—Poor flowers of this lovely variety were shown, and few would recognise it to be the same as that figured in THE GARDEN of February 24, 1894. The flowers were in the pale stage of early expansion, and showed no trace of the brilliant colour they develop later. From Messrs. J. Veitch and Sons.

NYMPHÆA ODORATA ROSEA.—This is the rosy-flowered form of the North American Sweet Water Lily, by no means new or rare, being plentiful wild in the Cape Cod district, and known in gardens as the Cape Cod Water Lily. This also came from Messrs. Veitch.

CIRSIIUM ERIOPHORUM.—This is a handsome plant of the Thistle tribe, of biennial duration, and not of much importance for gardens. It grows about 6 feet high, the flower-heads being densely covered with a woolly substance, the blooms when expanded of a reddish-purple colour. It was shown by Mr. C. Herrin, The Gardens, Dropmore.

GLADIOLUS DUTRIEUL DE RHINS.—One of M. Lemoine's fine hybrid varieties of the *G. Nanceianus* section, having large bold flowers with great breadth of petal, in colour light scarlet, slightly

feathered with white, a brilliant and striking kind. From Mr. Bain, gardener to Sir Trevor Lawrence.

PENTSTEMON HYBRIDUS GRANDIFLORUS.—The award in this case was made to the entire strain, about a dozen distinct varieties being shown, the flowers of fine size and bright colour, some of the reds being very good and practically self coloured. Also shown by Mr. Bain.

SWEET PEA LADY GRISEL HAMILTON.—This is a lovely self-coloured kind of a pale lavender-blue shade, the wings deepening into a heliotrope tint. From Mr. H. Eckford, Wem, Salop.

SWEET PEA BLANCHE BURFEE.—A very fine pure white-flowered variety of American origin, and already popular in gardens. From Mr. Eckford.

SWEET PEA MARS.—This also is self coloured, and we are glad to see these distinct kinds singled out for award in preference to the bicolor and tricolor varieties, which are wanting in distinctiveness and effect. Mars has fine flowers of a deep and brilliant shade of carmine-red, a telling colour in the garden or the house. This also came from Mr. Eckford.

A silver Flora medal was granted to Mr. Eckford for a very fine display of Sweet Peas in all his best varieties, each arranged separately in a tall glass vase. In addition to the kinds already mentioned, we noted Royal Rose, soft pink; Stanley, dark maroon; Ovid, rosy crimson; Emily Eckford, a decided blue self; Duchess of Sutherland, blush; Mrs. Eckford, cream; Monarch, purple-blue; and Countess of Radnor, pale mauve. Mr. W. E. Tidy, Brockhampton Nurseries, Havant, also made a fine display with these sweet flowers, arranging them in a sloping bank naturally and gracefully, the blooms being cut with their shoots. Most of the best kinds in cultivation were also to be seen here, a bronze Flora medal being awarded. A similar award went to Messrs. Dobbie and Co. for a fresh and varied lot of Sweet Peas. The group of hardy flowers from Mr. W. Prichard was noteworthy, the blooms remarkable for their freshness. The best were *Coreopsis lanceolata*, *Chrysanthemum maximum* in variety, a seedling form of Mr. Prichard's raising, extra fine; *Helianthus rigidus*, *Platycodon grandiflorum* and *P. Mariesi*, *Campanula rotundifolia alba*, *Genista tinctoria elata*, *Spiræa venusta* and *S. palmata alba*, *Physostegia virginiana*, the type and its pure white form, and *Asclepias tuberosa* with large trusses of orange-scarlet flowers. Some good *Phloxes* were prominent also, especially *Pantheon*, of a lovely salmon-pink shade; Jean Bart, rosy crimson; Figaro, rose-pink; and W. Robinson, pink, with fine large flowers. A silver Banksian medal was awarded, and a similar award went to Messrs. G. Paul and Son for a group of hardy flowers, those most notable being *Sea Hollies*, *Heliopsis patula* and *H. scabra*, with rough stems and deeper orange flowers than those of *H. patula*, *Rudbeckia purpurea*, *Campanula carpatica* Robert Parker, *Phloxes*, and *Veronicas*. Several fine new *Cannas* also came from Messrs. Paul, one variety less than 1 foot in height, yet flowering abundantly. Messrs. R. Wallace and Co., of Colchester, again showed some fine Lilies, a quantity of *L. chalcedonicum*, conspicuously bright, its scarlet flowers in striking contrast to those of the others shown, which included *L. auratum*, *L. longiflorum*, *L. japonicum Colchesteri*, *L. Browni* and others. Their new Day Lily was again shown, and two charming *Calochorti* that have not been seen before this season, namely, *C. Plummeræ*, which has large deep lilac flowers, clothed at the base with long yellow hairs, and *C. Weedi*, which is yellow, with hairs distributed all over the inner surface of the petals and forming a characteristic fringe upon their edge as well. A silver Banksian medal was awarded. Mr. Cannell received a like award for a charming group of *Carnations* and *Picotees*, the best self being *Cannell's Scarlet*, very bright; F. T. Tasker, light red; Mephisto, dark crimson; and Miss Mary Dyke, yellow; whilst *Picotees* worthy of note were *Brunette*, *Esther*, Mrs. Sharp, Mr. Dodwell, Favourite and Mrs. C. J. Shaw, new an

very pretty, with a light crimson edge. *Canna Queen Charlotte* was also well shown by Mr. Cannell. Messrs. Peed and Sons were awarded a bronze Flora medal for a good group of *Gloxinias* in variety, self and spotted kinds. Messrs. J. Veitch and Sons showed a group of the Javanese *Rhododendrons* made up of small plants comprising the best varieties, and sent to show that these beautiful greenhouse shrubs flower freely in quite a young state. A silver Banksian medal was awarded. Messrs. Cripps, of Tunbridge Wells, showed *Mutisia decurrens* and *Schubertia grandiflora* in flower, receiving a bronze Banksian medal; whilst similar awards went to Mr. Walker, of Percy Lodge, Winchmore Hill, for *Achimenes*, and to Messrs. Webb and Brand, of Saffron Walden, for a few spikes of double *Hollyhocks*. *Salpiglossis* was finely shown by Mr. Bain, gardener to Sir Trevor Lawrence; and *Cockscombs* came from Messrs. W. Cutbush and Sons. Mr. F. W. Moore, of the Botanic Garden, Glasnevin, was accorded a vote of thanks for handsome flower-spikes of *Crinum Powellii* and its pure white form; *C. yennense*, which has a long tubular pure white flower, its segments broad and bluntly pointed; *Agapanthus minor* and *A. Mooreanus* all cut from the open ground. Mr. J. T. Poë again showed *Browallia Jamesoni*, the same plants as appeared in the spring, but which have since been planted out in the open ground and lifted. Mr. C. Herrin showed a fine bunch of a handsome sweet-scented *Carnation* named *Dropmore Clove*, and Mr. R. P. Brotherston sent *Germania* in fine form from Tynninghame, where it does so well. Mr. Mount, of Canterbury, showed a bunch of a scarlet self named *Nora*. *Gloxinia Holborn Gem* is a spotted variety shown by Messrs. Carter, of High Holborn. Messrs. J. Laing and Sons exhibited several of their new double-flowered *Begonias* and two new *Caladiums*, and Mr. G. Farini, of Forest Hill, showed *Begonias*. *Begonia Duke of York*, a fine coloured leaved variety of tall growth, was shown by Messrs. Sander, who recommend it for training up pillars, and a double-flowered variety named *Marquis of Londonderry* was sent by Mr. Rowntree, of Norton, Stockton-on-Tees. *Pansies*, especially the lovely varieties of Dr. Stuart's raising, were admirably shown by Mr. W. Baxter, of Woking.

#### Fruit Committee.

There were some fine exhibits of fruit before this committee. Probably the best collection of *Gooseberries* ever staged was sent by Messrs. Veitch. There were also some excellent *Tomatoes* and *Peas*.

A first-class certificate was awarded to—

**TOMATO DUKE OF YORK.**—A very handsome fruit, quite smooth, round, and of great depth, rich scarlet in colour, and a tremendous cropper. The fruits are very solid and of first-class flavour. From Mr. Ryder, Northumberland Nurseries, Orpington.

Messrs. Veitch and Sons, Royal Exotic Nurseries, Chelsea, staged a very fine collection (some 150 varieties) of *Gooseberries*, cordon growths of the same being arranged at the back of the dishes. *Currants* in variety were also staged, with four boxes of *Cherries*. The best *Gooseberries* were *Highlander*, *Speedwell*, *Crown Bob*, *Lion*, *Monarch*, *Wonderful*, *Magnet*, and *Washington* among the red kinds. Of yellows, *Candidate*, *Drill*, *Lady Houghton*, *Leviathan*, *Railway*, *Traveller*, and *Trumpeter* were very fine. The best green kinds were *Fearless*, *Green Overall*, *Keepsake*, *Lofty*, *Matchless*, *Shiner*, *Souter Johnny*, *Stockwell*, *Telegraph*, *Waggoner*, and *Weathercock*, the best white kinds being *Alma*, *Antagonist*, *Eagle*, *Freedom*, and *Overseer*. The *Red Currants* were notable for size, the best kinds being *La Versaillaise*, *La Constante*, *Cherry*, and *Large Grape* (silver-gilt *Knightian* medal). Mr. J. Walker, Thame, Oxon, staged some forty dishes of *Gooseberries* and three of *Currant*, Walker's *Magnum Bonum*, a large red kind somewhat like the *Cherry*. The *Gooseberries* were very fine, the best being *Lord Derby*, *Snow-*

*drift*, *Drill*, *Fascination*, *Clayton*, *Overall*, and *Australia* (silver *Banksian* medal). Mr. Peters, Given Grove Gardens, Leatherhead, staged twenty-four varieties of *Gooseberries*, all good and well set up, the fruits being noted for their clean appearance. The varieties in many cases were those noted in the previous collection. They well merited the award given (silver *Banksian* medal). Some very fine *Madresfield Court* (*Grapes* were sent by Messrs. Wells, Hattonhurst, Hounslow, the berries large and well coloured (silver *Banksian* medal).

Messrs. Johnson, Boston, Lincoln, sent forty varieties of *Peas*, mostly large kinds, their new *Boston Unrivalled* being among the number. This is a very fine *Pea*, and was requested to be sent to Chiswick for trial. Such varieties as *Gradus*, *Goliath*, *Gladiator*, *Epicure*, *Duke of York*, *Daisy*, *The Queen*, *Wem*, *Stratagem* and *Critic* were very fine. There were also good dishes of *Longpod* and *Exhibition Broad Beans* (silver *Banksian* medal). From Mr. Carmichael, Pitt Street, Edinburgh, were sent seedling *Strawberries*, the results of crosses from *Waterloo*, *Elton Pine* and *British Queen*. The committee desired plants to be sent to Chiswick to test cropping qualities, the flavour being considered very good. Mr. Gilbert, Burghley Gardens, Stamford, sent very large *Peaches*, the variety being *Late Admirable*. The same exhibitor also sent seedling *Cucumbers*; these were requested to be sent for trial. From Dr. King, Spalding, Lincoln, was sent a seedling *Tomato*, but too much like *Dedham Favourite*. Messrs. Letellier et fils, Caen, France, sent young *Gooseberry* trees, quite spineless, the fruit also being staged, but not noted for high quality. Messrs. Veitch sent a promising new *Nectarine* named *Précoce de Croncels*. It is stated to be the earliest *Nectarine* grown and is a nice-looking fruit. It was, however, much too ripe. The same firm sent early *Pears*, *Doyenné d'Ete*, *Citron des Carmes*, and *Jargonelle* (not ripe), and Mr. Gladstone and *Red Juneating* or *Early Margaret Apples*. New seedling *Melons* were sent by Mr. Thomas, Frogmore, and Mr. Wythes, Syon House. Mr. Bain, Burford Lodge Gardens, Dorking, sent a variety of edible *podded Peas*. From the *Jadoo Fibre Co.*, Teignmouth, was sent a sample of *Potatoes* grown in the fibre. This was most interesting, there being a heavy crop of tubers and beautifully clear in the skin, showing the value of this material for forcing. Mr. Rees, Welford Park, Newbury, sent a new seedling *Cherry*, but too ripe. *Filberts* that had been kept since the 1893 crop were sent by Mr. Griffiths, Bilston, in a very fine state of preservation.

The lecture on "The *Carnation* in Scotland" was read by the secretary in the absence of Mr. R. P. Brotherston, who prefaced his paper by quotations from writers of 300 years ago, which proved that even in those days it was a popular flower, and in the estimation of those who grew it was counted next in importance to the *Rose*, a position it as worthily fills to-day. It was remarked incidentally as a curious fact that certain varieties which do well in Scotland, producing full and large flowers, fail to do so in the south of England, Mrs. Muir being one of them, whilst, on the other hand, *Cantab*, which is a sweet and perfect kind in the south, gave in Scotland poor, loose, shapeless flowers. These were exceptions, however, and as a general rule most of the best kinds of the day were found to do very well indeed. In the practical details of culture, special importance was attached to the necessity of early layering and early planting. The first layers this season were put down three weeks ago and the work was completed in ten days. The time for planting was the first and second week in September, as this enabled the plants to get a firm root-hold before the winter. Firm planting was most important, but after sundry experiments he had come to the conclusion that deep planting was wrong and opposed to the natural requirements of the plant, which was really of a shrubby character. The best results

came from short-stemmed layers that had the roots firm in the surface soil. As regards manure, it was doubtful if it was ever beneficial, and at any rate in a fresh state should never be applied to ground shortly to be planted with *Carnations*. If food was needed it would be best supplied through the agency of one or other of the chemical manures, but he had been very successful with *Carnations* following *Potatoes*, and in his case it was not even necessary to dig the ground again. For yellow *Carnations* it was advisable to give a good dressing of good leaf-mould and, if possible, raise the bed 2 inches or 3 inches above the surrounding level. He also practised and would advocate thinning, not only of the buds, but flowering stems and grass as well. The diseases that troubled growers in the north were fewer than those that afflicted southern growers, the most troublesome being a little eel-worm, whilst they had besides to contend with green-fly, which at times was very troublesome. As regards varieties, those of German origin were sturdy and had well-made flowers, but there were few suitable for gardens. The French kinds were lovely as garden flowers, but the tendency of most of the flowers was to droop. In the English varieties were to be found all one could desire—noble, sweet and distinct sorts that held their flowers up well.

#### NATIONAL CARNATION SOCIETY.

JULY 24.

This show on Wednesday in interest and extent exceeded the expectations of the most sanguine supporters of the society, and quite justified the new departure that has been made in making it a special fixture. It has for many years past been held in conjunction with the R.H.S. meetings, but latterly there has been too much crowding of the exhibits in the limited space that the Drill Hall affords. Through removing it to the Palace the society was enabled to add one or two additional features, as, for example, dinner-table decorations of *Carnations*, which brought out a spirited competition. Altogether we do not remember to have seen a more interesting show of *Carnations*, and it was all the more creditable by reason of the unfavourable season that has severely handicapped many growers. As a matter of fact, most southern growers found the date too late, and consequently there was a manifest change of places in the premier classes, most of the leading prizes going to midland growers in and about Birmingham, and among these Mr. Robert Sydenham carried all before him with his stands of magnificent flowers.

For twenty-four blooms, flakes and bizarres only, in not less than twelve dissimilar varieties, Mr. R. Sydenham was a good first, the exhibit having very fine flowers of Mrs. Kingston, George Melville, Sarah Payne, Lord Salisbury, Thalia, Othello and Robert Houlgrave. Messrs. Thomson, of Sparkhill, Birmingham, were second, and Mr. Turner, Slough, third. For twelve dissimilar flakes and bizarres, Mr. A. R. Brown, Handsworth, Birmingham, was first, showing fine flowers of *Thalia*, *Harmony*, *Lord Salisbury*, *Thaddeus* and *George Melville*. The second prize was secured by Mr. C. Phillips, Bracknell, Berks. Mr. W. Spencer, junr., Barnet, was first, and Mr. J. Keen, Southampton, second, for six varieties of flakes and bizarres. Mr. R. Sydenham secured the premier place for twenty-four *Picotées*, white ground, in not less than twelve varieties. These, like the flakes, were a grand lot of flowers alike in size and finish. The best were *Ganymede*, heavily edged red; *Favourite*, light red-edged; Mrs. Kingston, purple-edged; and *Little Phil*, rose-edged. Mr. C. Turner was second, and Messrs. Thomson third. Mr. Brown came to the front again with the best twelve *Picotées*, good flowers of *Little Phil*, *Ne Plus Ultra*, *Brunette*, *Favourite* and *Emma Geggie* being prominent. Mr. M. Rowan, of Clapham, was second, with smaller, but fresh and charming flowers. The best six dissimilar *Picotées* came from another Birmingham grower, namely, Mr. A. W. Jones, of Handsworth; Mr. W. Spencer, junr., was

second. For twelve dissimilar yellow ground Picotees, Mr. C. Blick, gardener to Mr. Martin Smith, Hayes, Kent, was first with a splendid lot, showing very fine flowers of Voltaire, Golden Eagle, Countess of Jersey, Mrs. R. Sydenham and President Carnot. Mr. C. Turner and Mr. J. Douglas were second and third. Mr. A. R. Brown, Handsworth, was first for six yellow ground Picotees, and Mr. W. Spencer, junr., second.

In the large class for twenty-four self and fancy varieties, not less than twelve distinct, which usually contains some of the best flowers shown, Mr. C. Blick was a good first with large fresh flowers. The best were Waterwitch and Sea Eagle, blush self; Eudoxia, rose; Duke of Orleans, yellow; Mrs. Eric Hambro, white, all self, with Almira, Voltaire, and Eldorado in fancy kinds. Mr. C. Turner was second and Mr. J. Douglas third. Mr. R. Sydenham was again first for twelve self and fancy kinds, Cardinal Wolsey, Mrs. Audrey Campbell, yellow; Corinna, yellow; Uncle Tom, dark clove crimson, extra fine; and Ruby, deep rose, being noteworthy. Mr. J. Walker, of Thame, was second, and Mr. C. Harden, Ash, Devon, third. The best six in these varieties came from Mr. Jones, of Handsworth, a first-rate lot of flowers, the second prize falling to Mr. Ffoulkes, Northgate House, Chester. Mrs. Orr, Bedford, was first for six Carnations and Picotees amongst those who had never previously taken a prize, Mr. E. Colby-Sharpin, Bedford, being second. Mr. Jones was first with Germania for the best self in any colour, and Mr. Sydenham second with Uncle Tom. In the corresponding class for fancies, Mr. C. Turner was first with Primrose Dame, and Mr. A. Spurling, Blackheath Park, second. For two cut flowers of any seedling raised from seed supplied by the society, and shown with their own foliage, Mr. E. Colby-Sharpin was first, with a deep apricot self, and Mr. J. F. Kew, of Southend, second.

The only exhibit in the class for twelve specimen plants carrying a good head of flowers was from Mr. C. Blick, but this lot was superb, the plants carrying from twenty to forty grand flowers, fine examples of cultural skill. For a group of Carnations arranged in a given space, Mr. C. Blick was again first with a more striking lot still, the plants and the flowers they bore remarkably fine, all of them being varieties raised at Mr. Martin-Smith's. Mr. J. Douglas was first for a smaller group and Mr. Charrington, Chislehurst, second. The dinner table arranged as for twelve persons brought out six or seven competitors, premier honours falling to Mr. Blick, but the high quality of the flowers was the chief feature of this arrangement, and the general opinion was that it was too heavy and overdone. For lightness and beauty as well, we very much preferred the table arranged by Mr. F. Seale, of Sevenoaks, to which the second prize was awarded. The best vase of Carnations came from Mr. M. V. Charrington, Hever, Edenbridge, and here we were glad to note that the judges had passed over the laboured arrangements of Carnations and Maiden-hair Fern in fanciful glasses and given the premier award to a vase of flowers and grass that was simplicity itself. Mr. C. Blick had the best sprays and button-holes, being awarded first in both classes.

The Turner Memorial prize, a cup of the value of £5, open to amateurs only, was well won by Mr. M. Rowan, who reserved his strength for this class and succeeded in beating Mr. C. Blick. Twelve bizarre and flake Carnations and twelve Picotees were shown, and Mr. Rowan's were a good lot, the more creditable because grown in a London garden. Mr. Douglas had the best crimson bizarre, and Mr. R. Sydenham the best pink and purple bizarre. The finest scarlet flaked Carnation came from Mr. Phillips, and Mr. Rowan showed the best purple and the best rose flaked varieties. Mr. Sydenham was first for heavy rose-edged, heavy purple-edged, light rose-edged and light scarlet-edged Picotees, Mr. Turner being first for a heavy carlet-edged flower. The best heavy red-edged and light red-edged varieties were shown by Mr.

Jones. For twelve Carnations of any class, each with a spray of Carnation foliage, Mr. Spurling was first and Mr. Harden second, and in the corresponding class for six the prizes went to Mr. J. F. Kew and Mr. Channidy, Oxford.

The Martin-Smith prizes again brought out some admirable varieties. Mr. Douglas was first for the best border kind, showing a fine dark crimson self. Mr. A. Spurling was second with a scarlet self named Paradox, and Mr. G. H. Sage of Ham House Gardens, was placed third with a lovely blush white variety, that perhaps merited a higher position by reason of its delightful scent, a quality all too rare in modern kinds. Mr. A. Spurling was first for six self border varieties, showing Paradox, scarlet; J. D. Pawle, yellow; Major, rose, and good seedlings. Mr. J. Douglas was second, and Mr. H. W. Weguelin, Shaldon, Teignmouth, third. The best nine garden varieties in flaked and fancy colours came from Mr. J. Douglas, Mr. A. J. Sanders, Bookham Lodge Gardens, being second, and Mr. H. W. Weguelin third. M. Ernest Benary sent from Germany a group of pot plants, embracing self and fancy kinds, but the best of them a long way behind the English varieties. Mr. T. S. Ware made a fine display with border Carnations in bunches in great variety, and Mr. Cannell also showed these well, and Begonias besides. Mr. Blick also had a very large exhibit of all the best kinds now grown in Mr. Martin-Smith's garden, and his method of arranging them might with advantage be imitated by others who bunch them up in a very stiff, formal way, and use Gypsophila to remedy the bad arrangement.

Other miscellaneous contributions consisted of hardy flowers largely and well shown by Mr. B. Ladhams, of Southampton, and Mr. M. Pritchard, of Christchurch, also Sweet Peas in quantity from Mr. H. Eckford, Wem, Salop, and Mr. W. E. Tidy, Havant, the best varieties in these being selected and enumerated in our report of the R.H.S. meeting.

## NOTES OF THE WEEK.

*Elæagnus edulis* has fruited freely this year in most places where it is grown. Some bushes in the Victoria Park at Bath, which were fruiting freely, have been cleared by the birds of the berries even before they were quite ripe.

*Kœlreuteria paniculata* is not usually a free-flowering tree in a young state, and we were agreeably surprised to see one in a villa garden on the outskirts of Bath. It was only about 8 feet high, but a pretty specimen, every branch crowned with an upright raceme of flowers.

*Telekia speciosa* is very striking now in the Victoria Park at Bath, a bold mass of it being isolated on the turf. It forms a dense and luxuriant mass of leaves, surmounted by a profusion of rich orange-yellow flowers, which make a fine display of colour and show well the fine effect that can be obtained from boldly massing the stronger hardy flowering plants.

*Clerodendron trichotomum* is represented by a handsome specimen in the Victoria Park at Bath, and, being quite isolated, has grown into a finely-proportioned bush nearly 6 feet high and as much through. In growth and outline it may be likened to a miniature Catalpa, but there is no resemblance as regards its flowers, which have been very profuse this season, and the bush was gay with them when we saw it.

*Gentiana asclepiadea*.—This is one of the latest flowering species, and a grand plant worthy of the best cultivation. It blooms through the latter half of summer and on into the autumn, quite half of the shoots, which grow 2 feet or more high, bearing flowers in clusters in the axils of the leaves. We noticed a fine, healthy mass of it flowering freely in the Victoria Park at Bath. *G. lutea* had also flowered well there.

*Linaria alpina albo-rosea*.—This is an exceedingly beautiful form of the old *Linaria alpina*

which we saw several years ago flowering with Mr. Thompson at Ipswich, and a tuft of it is blooming freely in the rock garden in the Victoria Park at Bath. The flowers of the type are of a light purple colour, but those of this variety are of an exquisite shade of pink, with the two characteristic bosses of rich orange at the tip of the flower.

**Hardiness of *Incarvillea Delavayi*.**—To complete what has been said lately in THE GARDEN about the hardiness of *Incarvillea Delavayi*, I may state that this beautiful plant withstood the cold of last winter under a simple covering of leaves both in my garden and in the garden of M. de Vilmorin at Verrières, near Paris. It has flowered abundantly this summer.—M. MICHEL, Geneva.

***Mutisia decurrens*** (referred to by Mr. Wood at p. 13, July 13) used to flower very finely in the open air in Messrs. Backhouse's nurseries at York, in a sheltered position facing south, on a bank forming part of the rockery, where it scrambled over some small conifers, the foliage of which served as a foil to throw out the rich-coloured flowers in strong relief, with very striking effect.—W. M.

**Sea Hollies**, though not often seen in public parks and gardens, are a pretty feature in the Victoria Park at Bath, and they attract much notice. *E. amethystinum*, in bold groups, was bright when we saw it, and *E. giganteum*, though it perishes after flowering, needs little care or culture here, seedlings springing up freely. Some of these self-sown plants, allowed to flower where they sprang up, were very fine alike in size and beautiful silvery colour.

**Carnations from Edmonton.**—Mr. H. B. May sends us flowers of some charming seedling self Carnations. *W. Robinson* is a fine scarlet self, a seedling from Winter Cheer, of the same sturdy habit and good form as that kind, and good in the open, from which the flowers sent were gathered. *Leonidas* is a very fine crimson Malmaison variety. *Mrs. S. Seager*, soft pink, and *Henry Gibbons*, in the way of *Uriah Pike*, but rather more scarlet and sweetly scented, are also good.

***Spiræa Lindleyana*.**—This is a noble shrub for warm and favoured places, and we have lately seen it frequently about Bath and its suburbs, quite a tree in dimensions. When of this size it is one of the most beautiful flowering shrubs that grow in English gardens. It must be large to display its fullest beauty, and no praise can be too great for such specimens as are to be seen in Bath 12 feet to 15 feet in height, throwing out long arching wands terminated by creamy panicles of bloom, some of them nearly 2 feet in length.

***Xanthoceras sorbifolia* in fruit.**—Several instances have been recorded this season of this shrub having flowered freely. A large and handsome bush of it quite 8 feet high, growing in the Victoria Park at Bath, has not only flowered well, but is now fruiting, this not being the first time it has done so. The fruits, borne in clusters of three or four and somewhat resembling those of *Pyrus japonica*, are of a light green colour, the seeds when ripe somewhat resembling Chestnuts. It is at all times, apart from its flowering and fruiting, a distinct, graceful and pretty-leaved shrub.

**Apple Beauty of Bath.**—The merits of this early Apple are not as yet sufficiently known, but it deserves wider popularity. In Messrs. Cooling's nursery at Bath we lately saw the original trees carrying heavy crops, and young trees were also bearing freely. Some of the fruits upon these last were sweet and juicy, and fast approaching ripeness at the time we saw them. The flesh is firm and the flavour brisk and delicious—altogether a most refreshing Apple to gather and eat from the tree in the heat of summer.

**Pea Daisy.**—This is undoubtedly an acquisition, and a Pea that will become popular amongst market growers as well as in private gardens. It possesses the qualities of the finest Marrow

varieties, is a profuse cropper, but its value to a great many lies in its sturdy growth. Although sticks would be used by those who have plenty of them, they can be dispensed with for this Pea with little or no disadvantage. We lately saw a large breadth of it in Messrs. Cooling's nursery at Bath. The haulm was unsupported, but the crop of large, well-filled pods was a very heavy one.

**The flowers in Hyde Park.**—We note with pleasure that there is much improvement here, mainly owing to the use of taller plants, which get rid of the flat, hard look of the older "bedding out." The Fuchsia is used gracefully, and charming it is to see here and there beds of good Stocks. Tall plants of Heliotrope and the blue Plumbago also help very well, and the Carnations and Cape Pelargoniums vary the garden, which looks fresh and charming. The main drawback is the old one of the beds being far too crowded and without relief. It would be a great gain if there was a little "air" about the spaces, which at present are too small between the beds.

**Campanula Vidali.**—This has probably never been seen in finer condition than as shown at the Drill Hall on Tuesday by Mr. Poë, who seems to take a delight in the cultivation of uncommon and beautiful plants. Three very fine examples of this were shown, each having a number of flower-spikes. These were each over a yard in height, and the stronger ones had nearly thirty flowers upon them. Their effect was superb, and they attracted very much notice. When well grown, as the plants shown were, this is a really noble Bellflower. Its flowers are large, of a waxy white colour, distinctly shaped, being contracted in the centre, but widely expanded at the mouth, whilst at the base inside there is a zone of rich orange-yellow colour. No doubt many who saw these noble specimens will turn their attention to the plant, and it is clearly worthy of good culture.

**Water Lilies at the Drill Hall.**—It was a very great misfortune that at practically the first appearance of the new hardy Water Lilies at a London show they should be represented by such poor flowers. We fear that some visitors must have gone away disappointed, and have come hastily to the conclusion that these noble flowers have been over-praised, which is very far indeed from being the case. The flowers of *N. Marliacea Chromatella* were fairly good, but no one would give a moment's notice to the flower of *N. odorata sulphurea* as shown and barely 2 inches across. Yet we have had this self-same kind with immense starry flowers quite 8 inches in diameter. Again, *N. Marliacea albida* was shown with flowers not so large as those of our wild Water Lily. This, too, is of great size, breadth of petal and noble form. Even *N. tuberosa*, long grown in this country, was shown in the same small state, and *N. Laydekeri rosea*, small, pale, and quite unlike itself. It would have been far better had they not been shown at all.

**Bocconia cordata.**—The Plume Poppy is at present very striking. Growing at the back of herbaceous borders associated with clumps of *Arundo conspicua* and a handsome mass of *Spiraea Lindleyana*, its effect is very picturesque and distinct, the tall stems 8 feet high, with their great panicles of blossoms shaded from reddish brown, or what might be more aptly described as burnt almond colour, to creamy white, being unique both in tint and form, while the dark green of the upper surface of the lobed leaves contrasts well with the light shade of their woolly reverse. The plant is very accommodating in the matter of soil, the strongest-growing clump that I have met with being situated on a bank where the staple is light and shaly, and is persistently robbed of what good it might otherwise contain by the roots of Fir trees and shrubs, yet, notwithstanding this, the stems of this specimen exceed 9 feet in height. The *Bocconia* is worthy of a place in all gardens that can afford room for it. When once established it must, however, be kept within bounds, as it is a veritable land grabber, and, if unrestricted, its suckers will encroach on the surrounding

ground, greatly to the disadvantage of its neighbours.—S. W. F.

**Lilium japonicum Colchesteri** was well shown at the Drill Hall on Tuesday by Messrs. R. Wallace and Co., of Colchester, and worthily merited the first-class certificate it received, whilst the prominence now given to it will assist in clearing up the confusion that exists between it and *L. Browni*. Possibly they are both forms of one species, but *L. japonicum Colchesteri* is the true *L. odorum*; whereas *L. Browni* has frequently passed under this latter name. What we recently noted at Kew as being very fine *L. odorum* is really *L. Browni*. In leaf growth they are most distinct, the leaves of *L. Browni* being long, narrow, and tapering to a sharp point; whereas those of the other form are short, broad, rounded at the tip, and bluntly pointed. The flowers of *L. Browni* are of a more reddish brown tint externally than those of *L. japonicum Colchesteri*, in which the outside colouring is less extensive, of a darker chocolate hue; the opening flower is inclined to be of a pale yellow tint, but when fully expanded it is cream-white, and last, but not least, it is by far the more deliciously scented of the two. It is easy to have one substituted for the other, but when one has both, the distinctions do not need a critical eye to perceive them.

\* \* *L. odorum* being the older and authorised name, why add to the confusion by certifying it under the name of *L. jap. Colchesteri*?—Ed.

**Some good new zonal Geraniums.**—La Belle Alliance, sent out this summer by the well-known French nurseryman and hybridiser, M. Lemoine, of Nancy, is quite a new break and one of the most distinct and delicately beautiful varieties I have ever seen, quite unlike any other that has been distributed to the public. The flowers are of medium size and of good form, far superior to those of many sent out by foreign raisers, which are, as a rule, thin, poorly formed, and distinctly inferior in flatness and roundness of petal to the fine varieties raised and sent out by our principal English growers. The ground colour of the new French variety above-named is of the most delicate shade of pale blush, and the three lower petals are thickly, and the two upper more sparingly, marked with clearly defined crimson spots, which impart a novel and quite unique appearance to the flower. This variety has also the additional merit of being prolific, as, when the flowers on the ordinary truss fade and fall away, no less than five subsidiary or prolific trusslets appear, each of them bearing from four to twelve equally perfect and pretty flowers. Altogether this new variety is a very charming acquisition to our greenhouses. Three new pure white varieties may also be mentioned; they are named Albion, Doctor Nancen, and Snowdrop. The flowers of these are all of fine form and substance, and absolutely pure, leaving it hard to understand how anything better can be obtained. Two new varieties have been added to the pretty French bicolors, Lady Newton and Exposition Universelle de Lyon, but neither is so fine as *Mme. Jules Chrétien*.—W. E. GUMBLETON.

**Notes from Chester.**—We send you sprays of some of the flowering shrubs that are just now in their best condition. *Rubus odoratus* has very bold and striking foliage; its masses of leafage make it a splendid subject for the foreground. Its large pink flowers are freely borne, and, extending over a lengthened period, they give a fresh front to the bank of boldly outlined leafage which supports it. The Ash-like branches of *Maackia amurensis* when seen in growth with the waxy flowers carried in compact panicles are very effective. The *Desmodium penduliflorum* has the look of a hybrid product between Sage and Lupine, and cut singly like the spikes sent on to you, is not nearly so striking as it is growing naturally in the open. Its colour is attractive and it shows out boldly and well. The Sumachs are perhaps plants most generally connected with autumn glory when the foliage is brilliant, but we send you one of the flowering tips of *Rhus glabra* with its dense cone

of blossom, and it is, as you will see, a prominent feature in the garden landscape even now. The *St. John's Worts* are always beautiful, and the specimen of *Hypericum androsamum* sent to-day is just as pretty as any of them. The berry-bearing plants are associated more or less with the wane of the year, though this is not a strictly accurate association. There is plenty of berried plants about now, though we are only just past mid-summer. A beautiful little coral-covered plant just now is the Crowberry (*Vaccinium Vitis Idea*). We send a few sprays of this dainty evergreen plant. Phloxes are gay in the wider borders filled with showy popular favourites, and the Begonias have already put a glowing beauty into the flower gardens, which is even brighter than Geranium effects.—DICKSONS.

Two interesting works came under the hammer at Messrs. Sotheby's sale room, Wellington Street, Strand, a few days ago. The first was a fine copy of Smith and Sowerby's "English Botany," with the supplement, making together 39 volumes, in tree marbled calf, the original first edition, coloured by hand. This choice set brought £22. The second was a subscriber's copy, in the original binding as issued, of Hooker's "Flora Londinensis," five volumes, folio, which realised £13 10s. This copy was specially coloured by Curtis for his friend Dr. Dickinson, of Liverpool.

**The weather in West Herts.**—The weather has been cooler than of late during the daytime, but, on the other hand, somewhat warmer at night. Since the beginning of the week the temperature of the ground at 2 feet deep has fallen 1°, and at 1 foot deep 4°. On the night of the 17th inst. the long drought came to an end. This drought had lasted nearly twelve weeks, during which period rain fell on only sixteen out of the eighty-one days, mostly in light showers, and to the aggregate depth of less than 1½ inches, or nearly 5 inches less than what may be regarded as a reasonable amount for the same three months. By way of contrast it may be mentioned that during the last six days 3½ inches of rain have fallen, which is more than twice the quantity deposited during the previous twelve weeks, and nearly an inch in excess of the mean for the whole of July. Of this total rather more than 2 inches, equivalent to about ten gallons of water through every square yard of surface in my garden, has already come through the heavy soil percolation gauge, the equivalent for the one containing light soil being 8½ gallons. In any ordinary rains with the soil so dry a month or more would have elapsed before any water at all passed through either of these gauges. But the rainfall on the 17th was so remarkably heavy, that, except where the ground had become hard on the surface, it penetrated to an unusual depth. A week ago my lawns were the colour of the gravel paths, but they are now quite green. Indeed throughout the whole garden the growth made by everything since the rain, considering the shortness of the time, has been truly marvellous.—E. M., *Berkhamsted*.

**Death of Mr. T. H. Rabone.**—It is with much regret that we have to announce the death on Saturday last, at the age of 62, of Mr. T. H. Rabone, for the last 26 years head gardener and steward to the Earl of Shrewsbury and Talbot, Alton Towers, Staffordshire.

**Names of plants.**—*Anon.*—3, *Sedum album*; 4, *Sedum Aizoon.*—*S. Dublin.*—2, Apple-scented *Salvia*; 4, *Justicia carnea*; 5, *Pyrus japonica*, fruit not edible; 1 and 3 next week.—*C. F. Landon.*—1, *Telexia speciosa*; 2, *Centaurea macrocephala*; 3, send better specimen.—*B. Smith.*—*Pyrus salicifolia.*—*F. Ashman.*—*Rhus Cotinus.*—*Collins Bros.*—*Veronica longifolia* var. *rosea.*—*Constant Reader.*—1, *Rubus odoratus*; 2, *Linaria repens* alba; 3, *Sedum casyphyllum*; 4, *Heliopsis* var.—*E. F. Clark.*—1 and 2; forms of *Sedum rupestre*; 3, *Sempervivum Haworthii*; 4, *Sedum rupestre*; 5, *Polygala Dalmaissiana*; 6, *Impatiens Noli-me-tangere.*

No. 1237. SATURDAY, August 3, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## FLOWER GARDEN.

NOTES FROM THE UPPER  
ENGADINE.

JULY is the time of Roses, and even in these high altitudes Nature does not disappoint us. Here at 6000 feet above the sea, and up to the snow line, she clothes the hills with a profusion of rosy blossoms. Although not the Roses which are now adorning English gardens, and in no way actually resembling them, the Rhododendrons of the Alps, or alpine Roses, are a fair substitute, if only the beauty of colour and general effect are considered. Fragrance they lack, but they are in perfect harmony with the wild scenery that surrounds them. Here Rhododendron ferrugineum is in perfection, the low-growing bushes being so thickly covered with flower that the effect in the distance is somewhat the same as of Heather in bloom on a Scotch hill; but on a nearer inspection numbers of flowers, which would be welcome in any English rock garden, are found half concealed among the pink branches. Conspicuous among the taller varieties are the golden stars of the Arnica and pale blue spikes of the Campanula barbata. The flowers of the Upper Engadine are too well known to require much comment. Every visitor to this favoured valley is struck by their beauty, and those who are lovers of rock gardens cannot fail to find ample scope for study on every hillside. The arrangement of each group of stones seems so perfect, that no garden rockery could be so artistically grouped, or each little crevice so successfully filled with such appropriate plants.

In a walk or climb of any distance the number of species that can be found is immense. Every few hundred feet one ascends, fresh treasures become apparent; those that were common below are left behind, and the flowers which were in full bloom at 6000 feet are just coming into bud 1000 feet higher. Just now the pastures in the valley are bright with the small light blue annual Snow Gentian (*G. nivalis*), while the larger and deeper coloured *G. acaulis* and *excisa* and *brachyphylla* and *bavaria* are only found at a still higher level. In the meadows in the valley one finds quantities of the sweetly scented little Orchid, the alpine *Nigritella*, and growing near it the common Burnet, which so much resembles it in colour. There are also thousands of spikes of the common *Polygonum bistorta* and a great quantity of the orange Hawkweed, alpine *Trifolium*, and the Mountain Avens (*Geum montanum*), whose soft fluffy pinkish heads of seed are now more conspicuous than the yellow flowers. Among the taller field flowers now coming into bloom we find the two handsome yellow *Gentians* (*G. lutea* and *punctata*), the poison-

ous dark blue Monkshood, the paler alpine Columbine, and here and there towering above all the showy blue alpine Sow Thistle. Among the rocks we find great patches of the little blue Campanula, and a perfect network of the *Sempervivum arachnoideum* and two larger varieties, all with equally brilliant red star-like blossoms, while every crevice and cranny are filled with some fascinating variety of Saxifrage (*aspera*, *Aizoon*, *muscoides*, *rotundifolia*, and many others).

A few hours' stroll up the mountain side will soon take one into another world of flowers. The upland meads are still studded with Primulas in bloom (*farinosa*, *longiflora*, *viscosa*, and the low growing *integrifolia*) and quantities of the purple long-spurred Violet, while the spaces under the rocks, which here and there crop up, are filled with the yellow *Viola biflora* and purple and white Butterworts. The grassy slopes are bright with the alpine Aster, and at still higher altitudes with the alpine and the sulphur Anemone. At this elevation, about 7500 feet, the rocks are covered with soft cushions of pink, and more rarely white, Androsace, their tiny flowers frequently so close together as completely to cover the green Moss-like leaves. In some places, as on the top of the Bernina Pass, the Androsaces are rivalled, if not surpassed, in brilliancy by the trailing Azalea (*A. procumbens*), which grows close to the ground and forms a carpet of coral-pink. In the same localities we also find the white Dryas, the sweet-scented pink Daphne, the blue dwarf Scorpion Grass (*Eritrichium nanum*), the purple alpine Toadflax (*Linaria alpina*), and the dainty little Bell-like flowers of the Soldanella. Higher up still, right into the snow, grows one of the prettiest of alpine flowers, the *Ranunculus glacialis*. This delicate-looking little flower, with white petals shading to red and red hairy calyx, grows at a greater height than any other flowering plant in Switzerland, having been found but a short distance from the top of the Finsteraarhorn.

One plant always associated in people's minds with the Alps, the Edelweiss, also grows freely in this neighbourhood. Children pick great bunches of it on the rocky slopes of the mountains between here and the Forno glacier, and these flowers can be bought for a few pence, but the plant is protected by law and the ruthless digging up of roots by the peasants is forbidden. But the searcher for this "luck flower" need not climb to giddy heights to procure it, as in some valleys it grows within a short distance of a good carriage road, and I have been fortunate in finding it on the rocks by the shores of the lake of Sils.

In this short space it is impossible to mention one-tenth part of the flowers which Nature has scattered here with such a lavish hand. Every roadside, meadow or Pine wood, every mountain path, craggy height or wild moraine offer a world of study for the botanist, a practical lesson for the gardener, and an endless source of delight to the amateur.

Malaja.

A. M. T. A.

## FLOWER GARDEN NOTES.

HERBACEOUS LOBELIAS.—I was responsible for the recommendation to leave herbaceous Lobelias in the ground (see page 455), and am glad that "S. W. F." has found no ill-effects from such treatment. It is, however, strange that on a cold heavy soil no surface protection is necessary, whereas in light dry ground I find it decidedly advisable. The inference must be drawn that these inmates of the flower garden are somewhat erratic in habit, and that it is difficult to know what to do for the best so far as their winter treatment is concerned, unless, as "S. W. F." suggests, half a dozen different methods are tried. If I remember rightly, one correspondent, who found annual lifting absolutely necessary, wrote from a soil very similar to that described by "S. W. F." Where these Lobelias are planted on a carpet of white Violas, it is advisable to keep the latter very hard picked, so that plenty of flower is showing when the spikes of the Lobelias are well developed. Possibly, as elsewhere suggested, a carpet of, say, *Mesembryanthemum* or silvery *Veronicas* is more suitable for them. In common with all herbaceous plants they have welcomed the splendid rains of July 20 and 21; prior to this the foliage was very limp and with little of the bright colour that is so attractive.

SURFACE MULCHING.—Writing of surface mulching in connection with the Lobelias reminds me to note that it plays a most important part in the cultivation of herbaceous plants, both as a protective agent in winter and a great incentive to growth, and the longer preservation of flower through the summer months. I refer to the matter at this season because there are instances to hand of the neglect of the winter mulching in the weak growth in the clumps of outdoor (I was about to write hardy) Fuchsias, and in the collapse of the old stock of *Antirrhinum*s and summer flowering *Chrysanthemum*s. Several gardeners have had to deplore the loss of *Gypsophila paniculata*, and concerning this and other things I heard the other day a very sensible remark, "Let us not depend too much on the hardiness of those things that cannot be guaranteed as perfectly hardy, but practise winter mulching by all means if there is the least suspicion of the inability to come safely through a very sharp winter." It may be added, after the experience of last year, that a heavy mulching is desirable. I have to acknowledge an error in writing two years ago of the non-hardiness of *Galtonia candicans*. The failure to appear in 1893 must have been due to a disturbance of the bulbs and not to severe frost, for the plants came up strong and well this year, and that despite the fact that in February, 1895, the frost penetrated the ground to a depth of 18 inches.

HARDY PLANTS FOR POTS.—I should like to draw attention to the use that can be made of hardy plants for pot culture at this particular season, whether they may be required for home vases or grouping, or to add to the attractions of the show tent. Their value in this direction is as yet imperfectly known, especially in those places where the amount of glass is insufficient to meet the demand with more tender plants. In giving the names of some particular things that will be found very useful and recommending this mode of culture, it may be noted that they should in the majority of cases be potted in early autumn, choosing for each the soil found most suitable for outdoor culture, plunging the pots to their rims in coal-ashes, and avoiding anything in the shape of coddling. Sound little plants, clumps, layers or corms must in all cases be chosen. In naming half-a-dozen really good things I should choose *Montbretia crocosmiflora* or *Pottsii*, *Gypsophila paniculata*, *Hydrangea paniculata*, *Carnations* *Ketton* Rose and *White Clove*, and *Campanula persicifolia* fl. pl. If to these are added a few pots of the Cape Hyacinth, a group can be made that would be hard to beat even with choice inmates of the stove, especially if, in addition, a dozen of such half-hardy things as *Francoa ramosa* and the old, but exceptionally useful, Fuchsias as *Mme. Cornelissen*, *Abundance* and *Mrs. Marshall*

are grown. As noted above, good sound corms of the *Montbretia* must be selected for potting, and in the case of the hardy herbaceous plants nice little clumps selected that are showing vigorous breaks. Border Carnations required for pot work I like to layer early, choosing the most vigorous grass. Extra care must be taken in the operation, not only to see that the knife is carefully used, but in the proper placing of the soil and in due attention to watering. The lifting for potting must also be carefully performed, getting well round and under the plants to prevent any injury to the roots. I think one of the most charming groups (on a small scale) I ever had was composed of a nice lot of the *Gypsophila*, associated with good plants of *Carnation Ketton Rose* and a *Clove* seedling something in the way of *Raby*, but much deeper in colour, more serrated and a non-splitter.

Claremont.

E. BURRELL.

#### PROPAGATING TUFTED PANSIES.

WHEREVER a very early spring display of bloom is essential, it is important that a start be now made with the cuttings, for there is no season in the whole year so suitable for this purpose as the month of July. Where plants of the proper stamp exist there will certainly be no scarcity of cuttings of the right sort. There are cuttings and cuttings, and I have upon more than one occasion seen gardeners inserting cuttings which were not of the right stamp, and which could scarcely be expected to produce good results. No one need ever hope for anything like a full measure of success who attempts to utilise the flowering growths of the current season for propagating. Plants raised from such cuttings as these, moreover, invariably produce only a sparse supply of cuttings next year. Next to this is propagating by division; indeed, I am strongly of opinion that a great many of the losses of which we hear from time to time are the direct outcome of divided plants. I was once led to divide my plants, and the following year was the most disastrous I ever had. Plant after plant collapsed quite suddenly and in a manner which surprised me, though my treatment was in every other respect similar to that I had adopted for years with every success. And then again, when I came to look for my usual supply of cuttings for the next year they were scarce indeed; in short, these divided plants seemed to be in a great measure hereof of the little remaining vitality during the summer flowering of the plants. Of some kinds I had happily a reserve batch from cuttings, which not only furnished me with the latter of the right quality, but also furnished an object lesson for the future. I think it is fairly obvious at a glance that a plant freshly rooted annually should be possessed of a greater natural vigour than one divided from a plant already much exhausted by the fresh demands made upon it during its flowering. If those interested in this particular style of gardening desire, they will quickly see a marked difference between the mass of roots produced upon a single plant from a cutting, to say nothing of the general vigour, and the sparse and feeble rooting that characterises a divided plant. The cutting is, in fact, an individuality of its own, representing an absolute renewal of vigour which cannot be secured by division.

It is very true that these tufted Pansies in many instances lend themselves to division, but it by no means follows that we obtain the greatest measure of success by its adoption. At page 35 of *THE GARDEN* I notice Mr. Burrell refers to a probable scarceness of cuttings, and it would be interesting to know whether the plants on which this is so noticeable are from cuttings or division. Of course, we have experienced a long season of drought,

which has retarded growth of all descriptions, but, apart from this, the plants, if from cuttings, should have their centres teeming with fresh young points. Every one of these points will root with the greatest ease, and drawing out the largest first and inserting them will give the remaining growths an opportunity of gaining strength. In a week hence the plants should be gone over again, and in this way it is quite easy to get fully 100 such growths from a single plant. Indeed, if circumstances demanded it, even more than this could be obtained. Mr. Burrell in the same note further observes, in reference to dividing the plants, that "This latter style of propagation will have to be more generally adopted than is usually the case, at any rate on all light soils." In reply I can only sincerely hope such will not be the case, as there is really no necessity for division—at least, for the majority and where a working stock exists. In this district (Hampton) the soil is exceedingly dry in such summers as the present one—in fact, dust-dry to a depth of 15 inches or 18 inches. Here I have raised many thousands with the greatest ease, and with very few losses indeed.

Where large numbers of these tufted Pansies are required it is far the best plan to plant a reserve patch for the purpose of propagation. By adopting this method the arrangement in the beds or borders need not be interfered with. When planting a reserve batch for stock I usually do so in nursery beds of about 5 feet wide. The soil must be previously well prepared by deep digging and burying abundance of cow manure fresh from the sheds. This item may be contrary to the generally accepted notion, but I attribute a great deal of my success with these plants in the exceptionally dry soil of this district to the free use of fresh cow manure. Not only does this enrich the soil, but it also provides that uniformly cool, moist rooting medium which is the greatest essential to success in very hot summers. Once the roots obtain possession of this layer of cow manure I regard them as almost proof against a summer like the present one has been. Plant in deeply drawn drills or shallow trenches, which permits of a slight earthing up. Planting is done the first week in October, and as the young shoots appear the earth is closed round them. In this way by the end of the year the July cuttings will have from a dozen to a score of shoots issuing from the base. But by earthing up, all these were protected from the winter then close at hand. From this time beyond keeping free of weeds little was done to the plants till the end of June. At this time they were cut down to within about 2 inches of the earth. Then followed a good hoeing and soaking of water if the weather was dry. At the time of cutting down, the centre of the tuft was generally full of young points, and these in a fortnight or three weeks make splendid cuttings. The kind of frame I used for some dozen years or more was generally a home-made one, 9-inch boards forming the sides and ends; a depth of 4 inches or 6 inches of soil was then prepared for the cuttings, the latter being simply drawn from the centre of the old plant, and, coming away for the most part with a heel attached, were inserted in the frame just noted without more ado. I always prefer cuttings with a heel, as I find these produce growth buds much more freely from the base than do cuttings made to a joint with the aid of a knife. Selecting only the strongest first, the whole collection is thus gone through again in about a week or ten days' time and until a sufficient number has been secured. The adoption of this method means an immense saving in labour alone, for

where thousands are required it is a long and tedious business to make these with a knife. Always insert quite firmly, water thoroughly, and shade lightly. In a month from inserting, these will be ready for transplanting to nursery beds preparatory to going into their permanent quarters, and where the work is done promptly the resulting plants will be a source of pleasure and surprise. Occasionally when pressure of other work has prevented the above work being done at the moment, I have, after cutting over the plants, filled up the centres lightly with finely sifted soil, extending the same over a 6-inch radius. By keeping this soil daily watered the fresh young growths quickly root into it. At the end of three or four weeks lift the entire plant and strip these young pieces off singly, transplanting into nursery beds or lines. In doing this I always discard any old wood or roots that may chance to come away with the young growth, believing that greater progress and vigour are secured by the building up of an entirely new plant annually. It sometimes happens that this earthing up of the tufts causes the young growths to elongate somewhat, and to counteract this it will be found a good plan to pinch out the point of each having this tendency. E. JENKINS.

#### Begonia Worthiana in the flower garden.

—"G. W." (p. 38) considers the above the best of the small-flowered section, but has he tried *Lælia*, *Aeme*, *Madame Lamarche*, *Paul Masurel*, *Message de Louvre*, *Charles Raes*, &c.? These nearly all made their appearance about the same time as *Worthiana*. All have medium sized flowers, but are far more showy than *Worthiana*. We have beds of all the above kinds by the side of *Worthiana*. *Lælia* makes a fine bed, the flowers of nearly the same colour as those of *Henri Jacoby Pelargonium*. The rage for size in the tuberous *Begonia* has nearly obliterated these smaller flowered sorts, but for effect the large-flowered kinds are nowhere beside their smaller flowered companions; even the old *Sedeni* makes a pretty bed. I suppose that the above kinds are now out of the trade, as I am being constantly asked where they can be had. These bedding *Begonias* should not be placed in pots at any time, and are far more satisfactory if they are never given glass protection.—FREDK. BEDFORD, *Straffan House*.

**Funkia Sieboldi.**—This handsome Plantain Lily is a valuable plant for effect and the most indispensable of the species. From the time it pushes up its strong cordate leaves until they drop at the approach of winter, it is always ornamental. The glaucous blue-green of the foliage is restful to the eye during the arid days of summer, while in the autumn the leaves assume a clear yellow tint that is almost equally charming. The flower-spikes, though pretty, are not particularly striking, being tall racemes of whitish lilac blooms that, however, harmonise delicately with the colour of the foliage. There are few places in the garden where *F. Sieboldi* would be out of place, but perhaps the sub-tropical portion or open spaces in the wild garden would be best suited to the display of its noble beauty. I have a fine clump, over 3 feet in diameter, growing in a shady position. This has produced over thirty flower-spikes this summer, and has been greatly admired. Snails are very fond of the succulent leaves, and must be rigorously exterminated from the neighbourhood of the plant if it is to attain its greatest perfection.—S. W. F., *Torquay*.

**Sweet Peas.**—When any popular flower becomes rapidly improved and increased there is always danger that such exceeding development will soon destroy popularity. Already we hear of demands that such popular flowers as *Begonias*, *Gloxinias*, and similar things should be simply regarded as seed strains, and certificated accordingly. Sweet Peas have got into the same category. Mr. Eckford, the great raiser, lists some fifty-five, and there are many others, old and new,

not included. As a result there is now, if variety, yet great sameness. But the worst feature is found in the many, not merely bicolors, but ineffective, indeed, unpleasing varieties with colours or combinations that are positively objectionable when viewed side by side with the best and most pleasing forms. It is a pity that, for the sake of making trade, so many of what seem to me and others to be so worthless, should have names and be put into commerce. They are bought and grown, they disappoint, and thus do Sweet Peas harm. Mr. Eckford had a very large collection at the Drill Hall on the 23rd ult., when a dozen of the prettiest are taken out—what was left might be discarded. What a pity it is that one half of the entire lot cannot be rejected altogether, and only the best grown and put into commerce. A dozen of the very best—as selected from the collection—are Blanche Burpee, white; Prima Donna, flesh; Royal Robe, pink; Meteor, bright carmine; Lady Penzance, reddish rose; Ovid, deep rose; Firefly, rich scarlet; Cardinal, crimson-scarlet; thus giving a very gradual deepening of colour, with a very dark one in Henley, maroon; then of blue tints, there are Lady Grisell Hamilton, pale mauve; Countess of Radner, pale blue; and best of all, Emily Eckford, rich blue.—A. D.

#### NOTES FROM MOUNT USHER, CO. WICKLOW.

THIS river-side garden is becoming richer and more popular every year. Its owners evidently do not rest, but by well-directed exertions in the intervals of a busy life are continually carrying out the deep and subtle laws of evolution. A garden, like every other natural growth, is either advancing or receding; there is no such thing as standing still. It is this constant progress, perhaps, that makes Mount Usher always new and always refreshing. Just now there is Rosa Brunonis tumbling like a silvery cascade over the dark roof of a creeper-clad outbuilding. Marliac's Nymphaeas (white, sulphur, and rosy red) are garnishing the pools, fringed with elegant Bamboos; and there, on the margin of the Water Lily pool in the wood, is Meconopsis Wallichii, of a blue soft and satisfying colour as the sky itself, each flower springing from a main stem over 6 feet in height. Nowhere else have I ever seen this exquisite blue Poppy finer or healthier than here just now. Another plant that is very beautiful is Sparaxis pendula, its 6-feet to 7-feet wands waving in every breeze, its slender stems arching as gracefully as any Bamboo, and its pale peach-tinted blossoms swinging bell-like from stems like the finest of wire. This is a hardy Cape bulb, seldom seen in all its beauty, but here it is now one of the most remarkable objects in a good garden. The new rock garden or stepping-stone bed is full of rarities, not the least being Campanula Zoysi and the dark purple Cyananthus lobatus, and here luxuriant masses and tufts of the Gentianella fringe every stone. But the glory of the "stepping-stones" just now is Dianthus Napoleon III. (a dozen large masses or more), not the usual worn-out unhappy bits, but great sheaves of dark green foliage having dense crimson heads of flowers. No description could do justice to this plant as thus seen luxuriant and happy. Its colour is most intense, a rich crimson-scarlet, before, or rather beside, which the scarlet of Tropaeolum majus on an adjacent paling of Ivy looks thin and poor in tone. There are Roses everywhere—China, Tea, and Hybrid Perpetuals. The great Apple Rose of Parkinson is most luxuriant, 10 feet or 12 feet high or more, its large and soft leaves Sweet Brier scented, and every shoot gracefully laden with its great hairy fruits, nearly as large as, but quite different in shape from, those of the

Ramanas Rose of Japan. Here I may allude to the above two Roses, and with them will join R. acicularis, which I lately saw at Newry, as being perhaps the finest three of all fruiting Roses; at any rate, if there are larger fruited and more fertile Roses or any even equal to the three above-named, I shall be very glad to hear of them.

Mount Usher lies in a deep and sheltered "happy valley" in Co. Wicklow, which is itself (like Kent in England) a focus spot of scenic beauty and gardening potentialities so far as soil and climate are concerned. Not only are horticultural rarities grown at Mount Usher, but even the most luxuriant of garden weeds are artistically utilised in suitable positions. The great Hemlock of Siberia (*Heracleum giganteum*), *Inula Helenium*, *Telekia speciosa*, &c., are made welcome in the wood garden, and the iron palisade fence, a most objectionable eyesore in most gardens, is here in part concealed by luxuriant Bindweeds, such as the great white *Calystegia sylvatica* from Hungary and the pink variety from North America or Japan. If I were to attempt the due relation of half the interesting plants now flowering at Mount Usher I should fail, but those who have enjoyed the privilege of seeing the place in its summer or autumnal beauty of tree and Fern or flower will agree with me that, like Killarney and other historical spots, this sweet little river garden at Ashford is really an Eden of the west.

F. W. B.

#### NOTES OF THE WEEK.

**Astilbe chinensis** is an uncommon hardy herbaceous Spiraea that has been flowering for a long time in Mr. Perry's nursery at Winchmore Hill. It is a graceful and very pretty kind, with plummy spikes of rosy pink and white flowers on stems about 18 inches in height.

**Milla biflora** succeeds well at Kew planted out in a frame devoted to bulbs of a similar half-hardy nature. It ought to be a popular garden bulb, its large long-stalked flowers being of the purest white and very beautiful, especially as seen growing among the narrow Rush-like leaves.

**Enothera marginata**.—This lovely Evening Primrose has been exceedingly beautiful during the early summer, its great white chalice scenting the evening air with delicious fragrance. It is certainly the gem of the family, and being a perennial should be in every garden.—S. W. F., *Torquay*.

**Rosa pyrenaica**.—Among wild Roses that are distinct in fruit this species merits notice. Some little bushes of it in the rock garden at Warley Place were laden with hips, which are 1 inch or more in length, of a bright red colour and clothed with hairs.

**Ipomæa Leari**.—This beautiful Indian species is now almost forgotten and rarely seen in gardens, but at Warley Place it still finds a home, and is conspicuous in a house of many fine stove climbers, giving a long succession of its bright blue flowers throughout the summer months.

**Asparagus decumbens**.—Among plants suitable for hanging baskets to adorn conservatories there are few more beautiful than this. A magnificent basket of it hangs in the conservatory at Warley Place, the long light shoots, from 3 feet to 5 feet in length, forming a graceful picture of elegant growth.

**Crinum Schimperii**, an Abyssinian species flowering at Kew, is very distinct. Its leaves are of a decided glaucous tint on their upper surface, the flowers white, faintly tinged with blush externally. The petals are broad, bluntly pointed, narrowing considerably at the base, and the tips reflex greatly after the flowers have been cut a

few days. A strong scape was bearing six fine flowers.

**Lily show at Manchester**.—It will be seen from our advertisement columns that the great Lily show, which was announced to open on the 5th inst., is postponed till the 22nd. Special facilities are offered to gardeners who may feel disposed to visit this the first special exhibition of Lilies held in the country. There will also be a special exhibition of Grapes.

**Spineless Gooseberries**.—Messrs. Letellier et fils, of Caen, Calvades, send us some specimens of their spineless Gooseberry. It is a good and well-sized fruit, of fair flavour. We hope they will go on adding to these varieties, not striving after large fruit, but trying to get the delicious quality of some of the best Scotch dessert kinds.

**Pinguicula caudata**.—Mr. Greenwood Pim kindly sends us photographs of a very well-grown plant of the great Mexican Butterwort (*Pinguicula caudata*), bearing in all nine flowers and buds. We are always glad to see clear and simple photographs of good garden plants, but these pictures of Mr. Pim's are not quite up to his usual standard of excellence, and could not be well engraved.

**Koelreuteria paniculata**.—Here this shrub is flowering this year for the first time in sixteen years. Apart from its raceme of flowers the foliage is handsome all through the season, but in the autumn it is especially so when covered with the pleasing autumn tints. The plant here is also about 8 feet high.—E. M., *Swanmore Park, Bishop's Waltham*.

**Gaura Lindheimeri**.—This herbaceous plant is too seldom met with in gardens. It is now in bloom, its tall spikes of white and claret flowers being very effective. It is a perennial that is grown and increased as easily as are herbaceous Phloxes. It seems perfectly hardy, and soon forms large clumps, the flower-spikes rising to a height of over 3 feet.—S. W. F., *Torquay*.

**Clematis Viticella**.—Two fine varieties of the old Virgin's Bower Clematis flowering in the Chiswick collection are C. V. rubra grandiflora and C. V. kermesina. Both of them have flowers of a rich and most distinct shade of velvety crimson borne as profusely as upon the typical plant. The flowers of the former variety, however, are noticeable for their fine size and breadth of petal.

**Weigela Abel Carriere**.—This variety has been much praised, but certainly not in excess of its merits, for while it stands out conspicuously as one of the finest when all the varieties are in bloom, it has the merit of keeping up a succession. A bed near the Fern houses at Kew is filled with this kind, and the plants are again breaking out into profuse bloom at a time when flowering shrubs are mostly past.

**Meconopsis Wallichiana** is usually well grown in the rock garden at Kew, but last winter severely thinned the group of plants, only leaving two, which are now flowering, but decidedly of different tints. The finest plant has flowers of a pale mauve shade, but those of the other one are of the characteristic shade of clear pale blue. This fine Indian Poppy is worthy of the care it needs.

**Gentiana septemfida**, one of the best Gentians for the rock garden, is now blooming well at Kew. Its rich deep blue flowers, as effective as those of the Gentianella in spring, are borne in a crowded head or cluster at the top of a slender leafy stem about one foot in height. The flowers being too heavy for the stem to support erect, it is well to let the plants be near a rock, over which they can droop.

**Crinum Powellii album**.—The past severe winters have tried and proved the absolute hardness of C. Powellii, and doubtless the same degree of hardness characterises its white counterpart, which is flowering grandly at Kew in an open border against one of the houses. A splendid scape had five immense pure white flowers expanded at one time, with a number of buds to follow in succession. It is a worthy companion to

the pink-flowered type, and those who have the one should not long be without the other.

**Mazua Pumilio**, a charming little New Zealand plant, thrives well in the rock garden at Warley Place, and is now flowering freely. It forms a spreading carpet that hides the ground upon which the leaves lie almost flat, and it is fortunate that they do so, otherwise they would quite hide the tiny, but pretty flowers, which are of a pale violet colour, and borne singly on stems each little more than 1 inch in height.

**Lilium Kramerii** grows and flowers remarkably well in the rock garden at Warley Place, several groups of it being a prominent feature at the present time. It is satisfactory to note a gain in strength and in the number of flowers on each stem from the bulbs longest established. One group has now been four years in its present situation, and the strongest shoots are carrying four flowers, whilst one has borne five.

**Campanula glomerata alba**.—A pure white form of the familiar and showy clustered Harebell should become as popular a garden plant as the type itself, and we were pleased to see a quantity of it in Mr. Perry's nursery at Winchmore Hill. There was still a lot of flowers upon the plants even at this late season, as this variety, besides its distinctness of colour, sends up a succession of its pretty clustered spikes of bloom.

**Fruit of Prunus Pissardi**.—I have not noticed any mention of the good qualities of the fruit of the purple Cherry Plum (*Prunus Pissardi*). We have had several tarts made of it; these were excellent. The fruit is much liked by birds, so cannot be allowed to ripen on the trees, otherwise its warm brown colour and pleasant, though not decided, flavour would make it a desirable dessert dish.—GEORGE F. WILSON.

**Prunella Webbiana** is a distinct addition, and Mr. Perry, who has it flowering well at Winchmore Hill, thinks it a first-class rock plant. It will make a charming companion to *P. grandiflora*, which we recently noted as being fine at Kew. Its flowers are much larger than those of *P. grandiflora* and in striking contrast as regards colour. They are of a deep violet-blue shade and borne in crowded heads on short erect stems.

**Hunnemannia fumarifolia**.—This beautiful Mexican Poppy, favoured by the hot season, is flowering well in the rock garden at Kew, and the little colony of it attracts notice both by the light and graceful glaucous leafage and the rich yellow flowers, with their cushion of bright orange-red stamens. It must be treated as an annual or biennial in an open, sunny place to ensure its doing well. A coloured plate of it was given in THE GARDEN of June 11, 1887.

**Carnationa Raby and the Old Clove** make a gay bed at Kew, where we are pleased to see that much more attention is being given to these flowers. Whilst many new Carnations seem to last but a few years, the good old Raby is as vigorous as ever and looks very bright, filling the centre of a long bed, broadly edged on either side with the Old Clove, which seems healthier in London and its vicinity than in many country gardens.

**Agapanthus Mooreanus**.—Some fine spikes of this pretty Agapanthus were shown at the last meeting at the Drill Hall by Mr. E. W. Moore, Glasnevin, and it is also flowering well at Kew in a frame beside the economic house where there is a strong plant planted out. It appears to flower quite as freely as *A. umbellatus*, the plant having eight fine spikes a yard or more in height and crowned with fine heads of bloom.

**Humea elegans**.—There are some very fine specimens of this graceful plant now flowering in the temperate house at Kew, where being planted out and with abundance of room overhead they have attained to dimensions such as we rarely see. One of the finest is nearly 15 feet in height, the upper 6 feet an exceedingly beautiful drooping pyramid of bloom, whilst many side branches are also terminated by long sprays of flowers.

**The Swan River Daisy** (*Brachycome iberidifolia*) is a graceful and lovely annual rarely seen

in gardens, but delightful, as we have seen it at Kew on several occasions lately in spreading masses of a yard or more across. It grows less than a foot in height, but completely hides the ground with a sheet of bright blue Daisy-like flowers, which are extremely pretty when seen near at hand and distinctly effective in the distance.

**The Agapanthus** in its blue and white forms is now a pretty feature in the Chiswick Gardens where it is planted out for the summer months, the plants filling a raised bed near the rock garden. They are carrying fine heads of bloom, and the white form is quite as fine as the typical blue. This way of using the old African Lily might be extended in gardens, as the plants need much less attention during the busy summer months.

**Venidium calendulaceum** may be grown as a half-hardy annual, or propagated by cuttings in autumn, but in any case it is a brilliant summer flower. It is evidently a favourite plant at Warley Place, as we saw several masses of it, and the effect was superb, with hundreds of single orange-yellow, Marigold-like blossoms fully out in the bright sun. It not only flowers profusely, but lasts long, spreading over the ground and blooming as it grows.

**Pratia angulata** is an alpine gem that flowers from the summer onwards, but is so diminutive that it has little chance of growing if in proximity to taller plants. In the rock garden at Warley Place these little plants have a suitable nook to themselves, and this one is very pretty, a mantle of rich green spreading over the ground and acting as a foil to its pure white blossoms, which, though small individually, are very effective in the mass.

**Tufted Pansies**.—There is plenty of evidence at Kew that tufted Pansies can be well grown even during hot seasons and on tight soils if the cultural details are adapted to the needs of the plants. Four beds near No. 4 house were pretty some weeks ago with a combination of English Irises and Pansies, but they are even prettier now since the Irises have gone to rest. The Pansies cover the beds and present to view a perfect sheet of fresh, sweet flowers. The varieties are Countess of Hopetoun, Skylark, Archie Grant and Formosa.

**Symphandra Kaufmanni** is a pretty biennial Bellflower that Mr. Perry grows well, and we saw a good batch of it, some of the plants being in bloom, others making strong rosettes of leaves and gathering strength for next year's flowering. In habit of growth and blooming it much resembles a Canterbury Bell. The flowers are ivory-white, large and bell-shaped, less expanded at the mouth than those of Campanulas, but disposed in a graceful branched pyramid about 1 foot high. It is quite hardy at Winchmore Hill.

**A noble specimen plant**.—At the recent flower show held in connection with the meeting of the Northamptonshire Agricultural Society at Wellingborough, a magnificent example of *Encephalartos Vroomi* was staged by Mr. C. Watkins, of Wellingborough. The plant when extended was over 15 feet in diameter and it had some seventy to eighty finely-developed leaves. So much space was required when the leaves were fully extended, that it had to be staged in the open air. Probably it is one of the finest specimens in the country.—R. D.

**Pentstemons at Burford Lodge, Dorking**.

—One of the leading features in the way of hardy plants Mr. W. Bain has provided in the gardens at Burford Lodge is a superb bed of Pentstemons raised from seed sown in January last. The plants are now in full bloom, and the quality of all is very high. Some spikes of these came before the floral committee of the Royal Horticultural Society held on the 23rd ult., and an award of merit was made to the strain. Taking these superb varieties as evidencing what may be obtained from seed, it is obvious that the naming of Pentstemons, unless the varieties have some

unusual novelty of character, is scarcely necessary.—R. D.

**Commelina celestia**.—This pretty and continuous flowering plant, although not quite hardy, is worth the trouble involved in lifting and storing its roots through the winter, or with generous treatment it may be successfully grown as a half-hardy annual. A bed of it is pretty at Warley Place. It strongly resembles the *Tradescantias*, with its erect stems and sheathing bright green leaves. When in bloom it is sure to attract notice by the richness of its colour, the flowers being of a deep Gentian blue. There is also a pure white variety.

**Lilium Browni var. leucanthum**.—This grand Lily is flowering well in a bed near the temperate house at Kew, and both by its robust habit and fine form completely dwarfs *L. longiflorum*, which fills the remainder of the bed. The stems are about 4 ft. in height, and the strongest one has five large flowers of great substance, very long in the tube and less reflexed at the tips of the segments than those of the typical *L. Browni*. The perianth divisions are creamy white, but the tube of the flower is of a lovely shade of soft clear yellow, free from spots or markings of any kind. The flower is also white externally with a narrow green band down the centre of each segment. This is altogether a noble Lily, as robust in habit as it is handsome in appearance. A coloured plate of it was given in THE GARDEN for February 9 of this year.

**Cyphomandra fragrans**.—A large specimen of the Tree Tomato now flowering profusely in the temperate house at Kew is worthy of inspection, by reason of its distinct habit of growth as well as for its flowers. The branches spread out flat, maintaining a horizontal disposition, arranged as it were in tiers one above the other. The large oval pointed leaves are of a shining glossy green colour and the pendulous racemes of bloom hang from underneath them. It has a peculiarly uniform method of growing and flowering. A secondary branch is produced at every third joint of the growing shoots, starting away at a slight angle, and all the flower racemes appear at the point of divergence. Each raceme has about twenty flowers, which in the bud state are purple, but when expanded greenish yellow, with a purple streak down the centre of each segment. They are each about 1 inch across, but not pleasantly scented, as the name would lead one to suppose.

**Tigridia pavonia lilacea**.—The *Tigridias* are now in the height of their glory, the display made in a narrow border beneath a wall clad with *Ampelopsis Veitchii* by *T. pavonia grandiflora*, *T. p. alba* and *T. p. lilacea* being gorgeous. *T. p. lilacea* is, however, growing much more strongly than *grandiflora* or *alba*, the flower-stems reaching to a height of nearly 2 feet, and the flowers in some cases having a spread of over 8 in. No conception can be formed by those who have not seen these flowers growing in masses of the effect obtained—the brilliant red of *T. grandiflora*, the ivory-white petals of *T. alba* and the deep rose-pink of *T. lilacea*. In splendour no Orchid can rival these Mexican strangers, but the open border suffices for their needs. Make a point of obtaining full-sized and well-ripened bulbs in the first instance, and plant in April. They will do well in any soil but a heavy clay, which should be lightened with road-grit, leaf-mould and sand. In the autumn, when the foliage dies down, the bulbs should be lifted, dried, and stored in sand during the winter. In some favoured spots the bulbs may be left undisturbed. Some years ago I resided in such a locality; the soil was light and shaly, and the border being entirely sheltered from the north and east winds, the *Tigridias* improved year by year. My attempt to pursue a similar mode of culture in my present garden was nipped in the bud by the loss of the whole of my collection during the first winter, but I find that the little trouble of lifting and storing is well repaid by the lavish display, which is now at its zenith.—S. W. F., *Torquay*.

A VIEW IN HABBERLEY VALLEY.

THE pretty view of which an engraving is here given represents a pretty copse. Such as this often occurs near to or even adjoining gardens, offering charming opportunities for pretty gardening too good to be entirely neglected. At Munstead, Miss Jekyll made a delightful Primrose garden in a Birch copse, and in a Sussex garden we once saw a little piece of natural woodland adjoining the kept garden perfectly carpeted with the creeping Forget-me-not, with here and there in open spaces groups of hardy flowers naturalised and perfectly at home. The most beautiful of all spring gar-

and surrounded on all sides by tree-covered slopes, one enters by the foot-worn rock of red sandstone, and after passing the curve in the road the beauty of the scene bursts upon the spectator. A peculiarity of the place is the amount of silver sand found in the soil.

ORCHIDS.

SMALL-FLOWERED MASDEVALLIAS.

It is difficult to say what it is that is so attractive about the smaller-habited and flowering members of this genus, but the fact remains that

any adequate idea of what they are like, and one must view them, and closely too, to realise their many and varied charms. There is nothing particularly difficult in their culture, yet many fail with them, and the reason is not far to seek. Being so small there is not, to use a well-known idiom, much to come and go on with them. Small matters of detail, or what would be small with other kinds, mean a great deal to these, and inattention to their simple wants for a short time only proves very detrimental to their well-being. Perhaps the most important detail in their culture is keeping them free from insects—at least if this is not attended to all others will prove futile. In the presence of red or yellow thrips the plants literally dwindle away, these obnoxious little pests soon over-running the foliage to such an extent that healthy growth is impossible. Their habit, too, renders the use of strong insecticides unsafe, so prevention must be the order rather than cure. As soon as an insect appears the plants should be thoroughly sprayed all over with tepid rain water, and this washing repeated at frequent intervals until a complete riddance has been made. None of these species like much material about their roots, so the smallest sized pots convenient must be used. It is on this account unwise to rear large tufts of these, for by breaking them up the health of the plants is improved, root action being freer, and the stock is likewise increased. The roots are more liable to die off in large pots during the winter, which is an additional recommendation to the use of the smaller pots. The drainage of the pots and quality of the compost must have careful attention, for these little plants enjoy and must have copious supplies of water at the roots, and anything close or heavy about them renders this impracticable. In potting, I usually mix the best of the peat fibre with clean freshly picked Sphagnum points, not using the white, partly decayed portions, and allow half as much peat as Moss. Small crocks and charcoal are ready to hand, but not mixed with this. The drainage being covered with a layer of Moss, a little of the mixture is wrapped round the base of the plant firmly, but not pressed so tightly as to injure the roots. Hold the plant in the exact position required, viz., with the base of the stems about half an inch above the rim, and fill nearly to this with the crocks and charcoal, dibbling in the peat and Moss firmly rather higher up than it is to be left, and trimming all off to a neat cone with a strong pair of scissors or shears. This is a light and porous root-run for the plants, and affords all the sustenance needed. A mild, moist and airy temperature not liable to fluctuations of any kinds is what they delight to grow in. They must be closely shaded from the sun all the summer, yet exposed to all the light possible during the dark winter days. They are rather erratic both in growing and blooming, and seem never entirely at rest; therefore only a little less heat will be required during the winter than the summer months. A capital way to grow these plants, and one that is not practised as often as may be the case, is to plunge the pots to the rim in growing Sphagnum. This keeps a nicely moist atmosphere about them, and does away with a good deal of damping overhead. Great care is, however, necessary that no slugs or other insects are introduced with the Moss, or they will play havoc with the young roots and flower-spikes. Should Sphagnum be difficult to obtain, any other green Moss will do, several native kinds having a very pretty appearance.

With regard to the time of repotting, I should not hesitate to do this at any season if

View in Habberley Valley, near Kidderminster. Engraved for THE GARDEN from a photograph sent by Mr. A. T. Bucknall.

dening can be carried out in places like this with a long succession of changing pictures from the time of Snowdrops onwards, but especially in Anemone time, as copses can be as completely carpeted with the Apennine Anemone as they often are by our native wood species. The Daffodil family, too, is a host in itself. Mr. A. T. Bucknall, who sent us the photograph from which the engraving was made, writes as follows:—

Habberley Valley lies on the north-west side of Kidderminster, at a distance of three miles from the town, and is known as one of the loveliest spots in the midland counties. Lying at the foot of Warshill (commonly pronounced Wassal) Wood,

anyone once taking an interest in them is not likely to relinquish their culture. The tiny flowers so peculiar in structure and so quaintly set upon the plants have a fascination for keen observers of Nature certainly not excelled and hardly equalled by those of any other Orchid, and many who pass them by as unworthy of notice would probably be charmed by their wondrous variety of form and individual beauty could they be induced to examine them closely. Let anyone who thinks them insignificant do so, and endeavour to describe the different colours, form, and size of any one of them, and possibly before his task is finished he will have altered his opinion. Description, in fact, fails to give

the state of the compost was so bad as to warrant interference, but possibly, all things considered, the spring is the most suitable time, if necessary removing a little of the surface again towards the end of September and replacing with new and sweet compost. To enumerate one half the species would take far too much space, nor is it necessary to grow them all. The undermentioned are all pretty and free-flowering, and will make an interesting little collection. M. Arminii, M. Carderi, and M. Estradae, all natives of New Grenada, with lovely tints of yellow, rosy-purple, and violet, M. Dayana, M. triaristella, M. vespertilio, and M. Wageneriana.

B. S.

#### HYBRID CATTLEYS AND LÆLIAS.

In most cases the crossing or hybridising of florists' flowers has been a comparatively easy task, the organs of reproduction being conspicuous and well within the reach of the operator. Their rearing has also, when compared with Orchid seedlings, been comparatively easy.

The important results of hybridising Orchids in various parts of this country as well as on the Continent are shown in the numberless forms of *Cypripediums* and other Orchids which one meets with in every collection now-a-days. The production of these mules, which is due entirely to the gardener's art and skill, has rendered the formation of the line of demarcation between species proper and plants which formerly were considered as mere varieties a matter of much difficulty, as it has now been proved beyond doubt that certain subjects which were held as distinct species were nothing more than natural hybrids, the artificial hybridising between the supposed parents or species with which the subject showed certain affinities having produced the plant expected by the operator.

On account of the close affinity that exists among *Cattleyas* and *Lælias*, between which genera the only clear distinction consists in the number of pollinia arranged in single series of four in *Cattleyas* and in two series of four in *Lælias*, hybridisation readily takes place between them, and numerous are now the forms obtained from crosses effected between plants belonging to these two closely allied genera. Yet it is worthy of remark that while all the forms of the *labiata* group upon which experiments have been made, and also the Brazilian species with two-leaved stems, cross freely with each other and with the Brazilian *Lælias*, which also cross freely with each other, none of the *Cattleyas* nor even the Brazilian *Lælias* will hybridise freely with the Mexican *Lælias*. With the exception of *Lælia anceps*, which seeds freely whether fertilised with the pollen of a *Cattleya* or that of a Brazilian *Lælia*, others have invariably proved failures, for it is on record that although numerous crosses have been apparently effected both ways, and that capsules have been produced, the seed has in every case proved barren.

The first successful hybridiser of Orchids, the late John Dominy, took up the subject in Messrs. James Veitch and Son's nursery at Exeter in 1855. Besides certain distinct forms of *Cypripediums*, such as *C. Domini*, *Harrisianum*, *vexillarium*, which even now are among the most distinct seedlings known, also *Calanthe Veitchi* and other hybrids which he raised at Exeter, he also produced the first hybrid *Cattleya*—*C. hybrida picta*—from *C. guttata* and *C. intermedia*. This was followed by *C. Brahmii*, the result of a cross between *C. Loddigesii* and *C. Aclandii*; *C. Dominiana*, between *C. maxima* and *C. intermedia*; and the most beautiful *Lælia*, or, as it is generally called,

*Cattleya exoniensis*, which was one of Dominy's earliest as well as most successful efforts, and of which, on account of the irregularity with which crosses were registered in the early days of Orchid hybridisation, the parentage is unfortunately involved in obscurity. Then came the equally beautiful *Lælia Dominiana* and *L. Dominiana rosea*, about the actual parentage of which there is also much uncertainty.

The successes obtained in the Exeter and Chelsea nurseries by Dominy and Seden in raising hybrids at length attracted the attention of others in that direction, and their efforts were greatly helped by the excellent paper read by Mr. H. J. Veitch at the Orchid conference in May, 1885. In the meantime, *Cattleya Mitchellii*, the result of crossing *C. guttata* Leopoldi with *C. labiata* Trianae, had been raised in 1874 by Mr. Mitchell, gardener to Dr. Ainsworth; *Cattleya citrino-intermedia*, the only hybrid from *C. citrina* yet known, *C. Harrisii*, *C. Miss Harris*, and *Lælia Novelty* had been raised by Dr. Harris, of Lamberhurst, Kent. These were followed by *Cattleya Baroness Schroeder* and *Lælia vitellina*, raised in Baron Schroeder's gardens; *Lælia Marriottiana*, raised from *L. flava* and *Cattleya Skinneri* by Sir Wm. Marriott; *Lælio-Cattleya Brymeriana*, raised by Mr. W. E. Brymer, of Dorchester, &c. Messrs. Sander and Co., of St. Albans, have either acquired or raised several hybrids in *Cattleya* and *Lælia*; Messrs. B. S. Williams and Son, of Holloway, have raised or acquired a *Lælio-Cattleya*; Messrs. Low, of Clapton, have exhibited one *Lælio-Cattleya*; Mr. Lewis, of Southgate, is credited with two *Cattleyas*, and Messrs. Backhouse, of York, with one, while Mr. Statter, of Stand Hall, Manchester, has raised *Lælio-Cattleya Clive*.

Continental Orchid growers and amateurs have also lately added to the list of garden productions, but it is worthy of remark that while in Belgium a considerable number of hybrids has been obtained, the efforts of the raisers appear to have been directed towards the production of *Cypripediums* only. The first *Cattleya* hybrid raised on the Continent (*C. calummata*) was obtained by Mons. A. Bleu at Paris, and is the result of a cross between *C. intermedia* and *C. Aclandii*. The same raiser also obtained *C. amœna* by crossing *C. Loddigesii* with *Lælia Perrini*. *Lælia juvenilis*, also of Bleu's production, is the result of a cross effected between *L. Perrini* and *L. Pinelli marginata*. *Cattleya Vedasti*, raised in Paris by Mons. Perreoud, is a distinct hybrid produced by the crossing of *C. Loddigesii* and *Lælia Pinelli marginata*. The same raiser also succeeded in producing *C. Alberti* from crossing *C. intermedia* and *C. superba*. To M. Ch. Maron, gardener to Mons. Darblay at St. Germain-les-Corbeil, France, we are also indebted for several hybrid Orchids. None are recorded from Germany; but *Lælia Horniana*, which is said to be a very distinct plant, was raised by M. Horn, who has charge of Baron Nathaniel de Rothschild's collection at the Hobe Warte in Vienna. By far the most brilliant, as also the most interesting, of all the hybrid *Cattleyas* of garden origin raised on the Continent, however, is undoubtedly *C. Mantini*. It is the result of a cross between *Cattleya Skinneri* Bowringiana as seed parent and *C. Dowiana aurea* as pollen parent, and, as might have been expected, the offspring from such parents is a really handsome plant, a robust grower and a most important addition to the section of autumn-flowering *Cattleyas*. The first plant of it was exhibited in Paris at the meeting of the Société Nationale d'Horticulture, when it created quite a sensation among Orchid amateurs and growers, and when first honours

were unanimously awarded to it. A most remarkable point in connection with this beautiful seedling, and one which may be taken as a sure indication of its being a particularly free-flowering plant, is its comparatively rapid growth and free-flowering character, for M. Mantini tells us that the hybridisation took place in October, 1889, the seeds were sown in November, 1890, and two plants flowered for the first time in October, 1894.

Now that numerous crosses have taken place in all parts of the country we may expect many plants of distinct character, but it is doubtful whether we shall have to record many new-comers of more striking appearance and of more sterling value than are possessed by some of the hybrids above mentioned or described. S. G.

***Cypripedium caricinum*.**—This singular, but pretty species does not meet with much favour among Orchid growers, possibly on account of its shy flowering habit, and I know of cases where its culture has been given up entirely for this reason. Still, while many growers do not succeed in flowering it, in other places it never fails to bloom annually and well. I believe the most frequent cause of failure in growing it is too much heat. Being a native of Peru, its natural associates are *Odontoglossums* and kindred Orchids, and with these it should be grown. The leaves are quite distinct from those of any other *Cypripedium*, being narrow and almost Grass-like in appearance. They are deep green and grow in tufts upon a creeping above-ground rhizome. The flower-spikes rise to a height of about 16 inches and produce the flowers successively as soon as the first ones fade, others taking their place. These are pale green in colour, the petals being brown or crimson on the ends, with a white wavy margin; the sepals are similar in colour, but not so much twisted as the petals. The lip is curiously formed, a tuft of black hairs ornamenting the staminode plate and variously coloured spots the enfolding portion. The compost for this species must be holding and the drainage free and open. Good fibrous loam and peat in equal proportions with chopped Sphagnum and charcoal will grow it well. Abundance of water is required during the growing season, occasional sprinklings overhead being also of service. A friend of mine who is very successful with this species keeps it quite dry for a few weeks in winter, and although this seems strange practice for *Cypripediums*, in his case the end amply justifies the treatment. In any case a slight cessation of growth is an advantage, and if this does not occur naturally the partial drying system is to be recommended.—H.

***Oncidium ornithorrhynchum albiflorum*.**—This, the white-flowered form of *Oncidium ornithorrhynchum*, first bloomed in the collection of the late Mr. J. Day at Tottenham in 1873 from amongst an importation of the species from Guatemala. It has always been a scarce and valuable plant and is generally considered difficult to grow. The plant that was exhibited on October 23 of last year at the Drill Hall by Mr. R. I. Measures, Cambridge Lodge, Camberwell, and gained a first-class certificate, is again throwing up its flower spikes. The treatment adopted with this plant was as follows: After flowering the plant was put at the warm light end of the intermediate house close to the glass, and was kept a little on the dry side until the growths began to make their appearance. Then water was given more freely, but with care during the severe weather in the winter and early spring. In the beginning of June the flower-spikes made their appearance. The plant was allowed to remain in the same position in the house until the second week in July, when the spikes had grown to from 12 inches to 15 inches long, when it was removed to the *Cattleya* house. The motive in view for removing the plant into a higher temperature was to endeavour to get the flowers expanded

before the fogs set in. Two years ago it was allowed to remain in the same house it had been grown in, when the buds were all destroyed by fog. Last year the warmer treatment, as stated above, proved so successful, that it has been adopted again. The plant is now showing fifteen flower-spikes, and when the flowers have expanded it will be removed to a cooler and drier house, where the flowers continue in perfection for several weeks. The material used in potting the plant is about two-thirds good fibrous peat and one-third Sphagnum Moss, with just a sprink-

treatment from that given to the Wardianum and similar types of the genus. The blossoms are produced about now upon the growths that have been made this season, often while the leaves are still green. These are of a beautiful golden yellow with maroon spots inside the prettily fringed lip. They are also sweetly scented, but, unfortunately, do not last longer than a couple of weeks. After the blooms are over the plants sometimes rest awhile, but they must not be forced to do so if they seem inclined to grow. As soon as signs of growth are apparent the plants

until well on the dry side, as indicated by the Sphagnum looking whitish and feeling rustling and springy to the touch. Enough must then be given to moisten it thoroughly and the plants left till they are again getting dry. The growth must be kept gently moving all through the winter and hastened on in spring by increasing the temperature. It likes a light position not far from the glass and an abundant supply of water to the roots. This Orchid frequently produces young plants upon or towards the end of the last matured pseudo-bulb, which may be taken off when they have had a season's growth and set going on their own account, nice healthy specimens being the result of grouping half-a-dozen or so of these in a pot or basket. *D. chrysanthum* was introduced from Burmah in 1828.

*Trichopilia suavis.* From a photograph sent by Miss Willmott, Warley Place, Essex.

TRICHOPILIAS.

This genus contains several really good and useful species which ought to be represented in all collections. Botanically, they resemble *Oncidiums* somewhat, but are quite distinct from the latter genus. Pilmannas are by some authorities merged into *Trichopilia*, but for garden purposes this would be a mistake. *Trichopilias* are all natives of Central America, and thrive best in a temperature distinctly higher than that of the coolest house. If there is no compartment intermediate between this and the *Cattleya* house, they will be better arranged in the coolest part of this latter structure, and so placed that they receive the full benefit of the ventilation. In habit they are pseudo-bulbous, and each bears a single leaf. The roots are not so persistent or strong as in some other kinds, and on this account considerable care is needed in preparing the compost and in watering. The usual peat and Moss mixture is suitable, provided it is kept in good order by efficient drainage and plenty of crocks and charcoal intermixed. While growing freely, plenty of water at the root is necessary—in fact, much more than is required by some stronger, more gross-growing plants, but after the pseudo-bulbs are formed this must be considerably lessened, and the growth well exposed to light and air in order to ripen it, without which it is useless to expect a good flowering return. During winter the plants only need enough water to prevent the pseudo-bulbs shrivelling, but an unduly dry atmosphere should even now be guarded against, as they are rather subject to the attacks of red-spider and thrips. The best time to repot *Trichopilias* is soon after the flowers are past and before the plants have made much growth. The base of the pseudo-bulbs must be kept well above the rim of the pot and water carefully applied at first. They are all suitable plants for amateurs and beginners in Orchid culture, for they are mostly cheap and easily grown. The flowering return, moreover, is ample, and, if all the species are grown, spread over a considerable season. Newly-imported plants are quickly and easily established by potting them up in clean crocks and placing them in the warmest part of the *Cattleya* house, giving a little compost as soon as the roots begin to show. A few of the better-known kinds are mentioned below.

ling of finely broken crocks. The whole surface should be covered with good living Sphagnum.—  
STELIS.

DENDROBIUM CHRYSANTHUM.

DENDROBIUMS will always be a favourite genus with Orchid growers, being in nearly every case useful, free-flowering and attractive Orchids. The subject of this note is no exception to the rule, and has the additional advantage of flowering after the majority of the other kinds are over. Though a deciduous species, it requires different

must be placed in a nice genial temperature to induce them to grow strongly, and when the young shoots have attained a length of about 2 inches they must if necessary be repotted. If left longer the roots will be pushing from the base of the pseudo-bulbs, and these will be injured in the operation of potting. Fairly large pots may be used, as *D. chrysanthum* is a vigorous rooter, and the compost should consist of rough lumps of peat, Sphagnum Moss, and charcoal broken to the size of a Hazel nut. Care will be necessary with the watering until the roots are well through the compost. The plants should not be watered

*T. CRISPA* is a somewhat variable kind, a native of Costa Rica, and brought to this country about 1850. It is possibly the most free-flowering of all, the blossoms being produced in succession from the base of the pseudo-bulbs in racemes of two and four. The sepals and petals are wavy, usually brownish crimson, frequently edged with white or pale yellow. The lip is deeper in colour than the sepals, spreading in front, the lower part enfolding the column. The throat has usually a stain of deeper colouring. It flowers at various times in the year, but usually during spring and

early summer. The var. *marginata* is a larger-flowered variety, usually blooming later in the season. The sepals, petals and lip of this kind are more or less edged with white.

*T. GALEOTTIANA* is an inferior plant to the last-named, the flowers not being so bright in colour. It flowers in autumn and has greenish yellow and brown blooms, produced on one or two-flowered scapes. This, too, is variable, some forms being much superior to others. It is a native of Mexico, introduced in 1859.

*T. MARGINATA* is another species in the way of *T. crispata*, one variety (*lepidata*) being very similar. Indeed, it is questionable whether they are really distinct species or simply seedling varieties, but that is a matter for botanists rather than gardeners. The flowers are each upwards of 4 inches across, brownish purple in ground colour, the lip bold and spreading, the sepals and petals margined with yellow.

*T. SUAVIS*, as will be seen by the accompanying illustration, is a beautiful large-flowering species deserving of the most extended culture. The pseudo-bulbs are about 2 inches high, very thin, and each bears a large deep green leaf. The flowers are very fragrant and produced from March to midsummer on short, decumbent spikes, which spring from the base of the pseudo-bulbs. The sepals and petals are not so much twisted as in the other species, creamy white, occasionally spotted with red. The lip has a yellow throat, the side and front lobes spotted with violet-rose. The variety *alba* is wholly white, save a blotch of yellow on the throat, while *grandiflora* is a stronger growing, larger and brighter-flowered Orchid than the type. *T. suavis* grows naturally at great elevations in Costa Rica, whence it was introduced in 1848.

*T. TORTILIS* is an easily managed, free-flowering species, very ornamental if well grown. The flowers are produced in summer and are remarkable for the twisted sepals and petals. These are brownish red, margined with yellow, the lip white in front with bright red spots, the inside of the tube crimson. Introduced from Mexico in 1835.

R.

#### SCHOMBURGIAS.

MANY of the species of this genus are rather small flowering and not particularly attractive, but a few deserve a place in collections where variety is looked for. They are South American plants, epiphytes, with erect leafy pseudo-bulbs a good deal like *Cattleyas* in habit and appearance. The flowers, proceeding from the apex of the pseudo-bulbs, are borne on long, upright racemes mostly towards the top. Some growers have found *Schomburgkias* rather difficult to flower, but a good deal depends upon how they are treated. All of them seem to like a light sunny position in a brisk moist temperature, the shading only being let down during the middle of the day to prevent the foliage being scorched. As much air as possible consistent with a high temperature should be allowed, as this conduces to a firm and solid growth and tends to keep the plants to their proper season. Growing under these conditions, obviously a good deal of water will be needed at the root, and this supply must not be in the least lessened until the pseudo-bulbs are quite finished. After this both heat and moisture must be reduced, not all at once, but gradually. Towards the middle of winter the plants may be kept perfectly dry with advantage, but the temperature must not rule too low. The *Cattleya* house is, in fact, the most suitable place for them, and they must be kept well up to the light even while resting. A little water will again be needed at the roots as soon as the spikes appear, and the supply increased as these develop and the plants are again on the move. Pots or baskets, as most convenient, may be used, the former perhaps for preference. They

must be filled rather more than halfway up with drainage, and a layer of Moss placed over this. Three parts of Sphagnum to one of good peat fibre, with some rough pieces of charcoal or potsherds, will be a suitable compost, and in potting or basketing, this must be laid firmly about the roots, the base of the pseudo-bulbs being kept well above the level. A few neat stakes will be required to fix the plants in position, as it is important that they do not rock about after being disturbed at the roots.

*S. HUMBOLDTI* is comparatively rare, though an old species described by Reichenbach as far back as 1848, and this was years after its first discovery. Its flowers are bright purple with a yellow centre to the lip.

*S. LYONSI* was introduced from Jamaica in 1853. It is a beautiful kind, well known and interesting on account of its being one of the few exotic Orchids that are self-fertilising. It grows about a foot high and bears strong erect spikes of bloom. The individual flowers are from 2 inches to 3 inches across, the sepals and petals narrow, rosy white, with purple spots; the lip also white spotted with purple and sometimes margined with greenish yellow.

*S. ROSEA* is another very old species found growing naturally on rocks at a great elevation in Sierra Nevada. The sepals and petals are deep purple, the lip light rose. It is said to be very free flowering and to produce shorter racemes than the majority of this species.

*S. THOMSONIANA* is a more recently introduced species, named in honour of Mr. W. J. Thomson, of St. Helens, with whom it first flowered. The blossoms occur on erect racemes and are light yellow on the segments, the labellum white with dark purple markings.

*S. TIBICINIS* is a strong-growing handsome kind, popularly styled the Cow-horn Orchid. The flowers are upwards of 2 inches across, the sepals and petals crimson-purple with maroon tips, the lip orange-yellow streaked with purple on the side lobes, the front usually white. Some variations exist in this species, the best form being that known as *grandiflora*.

*S. UNDLATA* was found growing on rocks at an elevation of 2400 feet near Pandi, New Grenada. The sepals and petals are wavy, brownish purple, the lip rose coloured, with white lines on the crest.

H.

#### THE WEATHER OF THE PAST SEASON AND ITS EFFECTS ON THE GARDEN.\*

I AM glad that our secretary has put this heading to my paper. It is the same as the heading to my paper this time last year, and it at once suggests that what I have to say on the subject this year is not anything very new, but is a continuation of last year's paper. And this is exactly what I wish to bring before you now, for the condition of the garden this year is so intimately and curiously connected with the weather and its effects on the garden last year, that my last year's paper is really quite incomplete without this year's record. I suppose none of us can remember two successive years so entirely unlike as 1893 and 1894. The one bright, clear, dry and sunshiny beyond all experience, the other dark, cloudy, wet and sunless to a really unpleasant extent; and yet I have little doubt that as the weather of this year was to some extent the result of the weather of last year, so I am sure that the condition of the garden was far more brought about by the weather of 1893 than by the weather of 1894.

Let us very shortly see what the weather has been since December 1, 1893, to November 30,

\* "The Weather of the Past Season and its Effects on the Garden." By Rev. Canon Ellice. Read before the members of the Bath Natural History and Antiquarian Field Club, December 12, 1894.

1894. Up to December 30 there had been but four days of frost, on one of which, the 3rd, the thermometer fell to 19°, but the 31st brought in ten consecutive days of frost, not very severe except on the 5th and 6th, when the thermometer fell to 14° and 13°. There was again frost on the 23rd and 24th. The rainfall of December was 2.59, and of January 2.63. In February there were five days of slight frost, and the rainfall was 3.43. In March there were four days of slight frost and the rainfall was 2.15. April was a fine month; there was no frost, but there was a rainfall of 2.17. In May there was one frost on the 20th; here in Bath and the neighbourhood it just touched 32°, though in some parts of England it was much more severe. Here it would have done very little mischief, but unfortunately it was followed by a day of bright sunshine, and the effects were disastrous and far-reaching; and I shall have more to say about it further on. The rainfall of May was 2.12, of June 2.19, of July 3.46, of August 2.67, of September 3.12, of October 4.30, and of November 5.49,\* and there were no autumnal frosts until the morning of December 1. The total result was that during the twelve months there were but twenty-six days on which the thermometer was below the freezing point, and the accumulated degrees were 151. That is really a very small amount of frost, and when you add to this that nearly the whole of this was in the early part of January when vegetation was for the most part dormant, and that the low readings probably lasted for a very short time, we may say that the minimum temperature was much above the average. But the rainfall was also much above the average; it amounted altogether to 36.34. This great amount of rain of course implies a great amount of cloud, and that means a small amount of bright sunshine; and even on days when there was no rain the sky was dull and sunless in an unusual degree.

Such (very shortly stated) has been the weather of the last twelve months, and now we can see what were the effects on the garden, and we shall at once see that the effects were largely brought about by the bright weather of 1893. In my last paper I ventured to make two forecasts; one was that we were not likely to have a very severe winter, and we certainly had not, for we cannot call that a severe winter in which hard frost only occurred on a few days in December and ten days in January. The other forecast upon which I ventured was that the long hot summer had added so much vital strength to all plants, that this year would be a good year for flowers and fruit. That forecast was almost but not quite right, and it would have been quite right but for the frost of May 20. From all parts there came the same record. In my own garden the flowering shrubs were laden with blossoms with a profusion that I never saw before; and from Kew the report was that in every portion of the gardens the flowering was quite phenomenal. Among the early flowering shrubs the *Magnolias* were perfect pictures of healthy bloom; fruit trees of all sorts were sheets of blossom, and *Roses* were full of promise; and so through all the flowering trees and shrubs, till we arrived at the *Tulip Trees* and *Catalpas* which were thickly covered with flowers. Unfortunately, in a large amount of this fair promise we were doomed to disappointment. The May frost destroyed all blossom that was in a certain stage; Pears, Plums, Peaches, and Apricots

\* I have taken these rainfall amounts from the record kept by Rev. C. Miles, Almondsbury. They are slightly in excess of the Bath record, but I think they are more accurate for Bitton.

had passed that stage and were comparatively unhurt; but Apples, Walnuts, Strawberries, Raspberries, and Currants were in many cases so injured in their blossoms that they bore little or no fruit, except in the few cases in which they were so forward as to be beyond injury, or so backward as to have their flowers unformed and so were saved. Gooseberries had heavy crops, and so had Pears and Filberts, but there were no Walnuts. Peaches and Apricots also had heavy crops, but owing to the wet and lack of sun the fruits not only ripened badly, where they ripened at all, but to a great extent they rotted on the trees. Bulbs were not as good as I had expected them to be, and I suppose, especially with the Lilies, that they have not recovered the drought of 1893.

The year was marked in a very unpleasant degree by two pests, weeds and earwigs. Among the weeds Thistles were especially abundant, and this abundance of Thistles was remarked not only all over England, but in many parts of Europe, and to an alarming extent in America. In my own garden I was not pleased to see a great number of Thistles of species which I had never noticed before, and the farmers in the neighbourhood told me the same tale with respect to the Thistles in their fields; they were very abundant and not of the common kinds. Grass was another weed that gave great trouble in the gardens, and for both the Grass and the Thistles we undoubtedly had to thank the hot weather of 1893, which ripened every seed. The Thistles will probably disappear, certainly in gardens and fields where they have not been allowed to seed; the Grass may give some little trouble in our flower beds, but it can be easily removed. Of the other pest I mentioned, the earwigs, I am not sufficiently an entomologist to say whether the abundance this year was at all owing to the last hot summer, but everywhere they were very abundant, and their special mission seemed to be to make holes in the wall fruit before it was ripe, into which the wet entered, and the fruit rotted on the tree. I very seldom have been troubled with earwigs in my garden, so if this year's abundance was owing to the bright weather of last year, I may hope that the dull weather of this year will clear them away.

I am afraid that among the effects of this year's dull summer must be mentioned a large amount of grumbling, and certainly it has not been a year in which there was a prolonged enjoyment of out-of-door life. Yet, like every year, this year with its peculiar weather has had its uses, and has had its own special lessons. Among the uses must be reckoned the ample supply of rain, which will go far to restore the average, and to make up the deficiency caused by last year's drought, and I certainly have learned more than one good lesson in garden work. I have never before had the lesson brought home to me so closely that all the beauty of our trees, our hedgerows, and our gardens is not produced by the particular weather of the one year through which we may be passing, but that it can all be traced back to many previous years. Perhaps it is not too much to say that whatever the beauty of a tree or shrub may be this year, it has got some of that beauty by little and little in every year of its existence. I have mentioned the phenomenal abundance of flowers this year on almost all trees and shrubs, but I should also have noticed the abnormal growth of this year's branches. I am sure that in many cases the growth of the branches on our trees and shrubs with corresponding abundant foliage has been quite three or four times

the usual annual growth,\* and for this we have to thank not the wet weather of this year nor the bright summer of last year, but the two combined. This year's wet would not by itself have produced the unusual growth, but it has largely helped it, and last year's heat would not have been sufficient to produce the effect if it had not been followed by this year's dripping summer. And I am sure also that we may go back much farther, and trace something, however little, in every year of the life of the tree or shrub that has helped to produce what we have seen this year. The vigour of an old tree or shrub is as much dependent on its vigour when it was young as the vigour of our manhood and old age depends largely on the vigour of our childhood and boyhood. This may seem a truism not worth notice; but though I am not one of those who think that every plant and animal was created for the use or pleasure of man, yet I do think that it adds something, perhaps much, to the pleasure of our gardens to think how the beauty of our gardens has been slowly growing up for our delight year after year, "man knoweth not how"; and it surely adds to the pleasure we may have, in planting and carefully tending young trees and shrubs, to think that what we are doing now is to give pleasure or profit in many distant years to those who will then be looking at them when we ourselves are passed away. Perhaps one or two instances of the way in which the vegetation of one year is provided more by the year or years that went before than by the present year may be interesting. If you take up a Grape Hyacinth now or a little later, you will often find the flower-spike not only perfectly formed, but even coloured some months before it shows above ground. If you bisect a large Fern, say a full grown Filix-mas in the summer, you will find no less than the growth of four years strongly shown. There are the outside fronds of last year; there are the full-grown fronds of this year; at the top of the throat (if I may so call it) you will find the crown of next year's fronds neatly curled up, and below that you will find the crown of the fronds of the year after next closely packed, but perfectly visible. The Tulip bulb has something of the same character; each bulb contains the flowering bulb of three years. The old writers said that you could also find the flowers of three years, but that is not confirmed by modern observation. The main fact, however, remains that no plant and no living organism except annuals, and perhaps not even annuals, contain only the growth or the flower of one year only.

Another lesson which I have learned from the weather of the years 1893-94 is the immense value of a

#### HOT DRY SUMMER.

I knew the value of such a summer in ripening the wood, but I never sufficiently observed that the effect went much further, and especially in warming the ground. Though the frosts of last winter were severe for the short time they lasted, they did very little mischief, and I put that down to the large amount of heat which was stored up in the earth during the long hot summer of last year. I am sure that this is one great secret of the way in which half-hardy and even tender plants are grown successfully in one garden and cannot be grown at all in a garden which may be a near neighbour. Soils vary greatly in the way in which they can take

\* I may mention as instances of the luxuriance of the foliage this year, that on the Paulownia grown as a shrub I had leaves 22 inches in length and 16 inches in breadth, and that on the hardy Japanese Banana (*Musa Basjoo*) I had leaves more than 4 feet long and nearly 2 feet broad.

in and retain heat, and this partly depends on their position being sheltered or otherwise and well drained, but far more on their constituent parts. A loose friable loam, especially on sandstone, with a gravelly sub-soil will absorb and keep an amount of heat which a wet clay soil can never acquire, and this heat shows itself not only in the abundant and healthy growth of all plants grown in it, but it shows itself also in the power of resisting frost. People are apt to talk of a frost as if it was something that came down from the skies and caught hold of the earth, whereas the simple explanation of frozen ground is that the radiation of heat from the ground is not equal to the cold atmosphere above it, and the depth to which frost penetrates is largely determined by the amount of heat in the earth, and so wherever means can be found to keep in the heat which exists in the earth, and wherever the earth is so warm that it can retain its heat in spite of all the cold air above, there frosts do little or no damage. This explains the difficulty which people who have been in the tropics often speak of, when they have seen beautiful tropical flowers growing in places where there are often sharp frosts; the earth has been so roasted by the tropical sun that a few degrees of frost lasting a very short time have no effect on the plants. It explains, too, how the possibility of growing tender plants does not so much depend on latitude, for there are parts in the north where many things can be grown which we cannot think of. At Castlewellan, in County Down, nearly four degrees north of us, Lord Annesley grows a marvellous collection of plants which we should consider too tender to attempt here, including a large number from Australia, New Zealand, and the Cape. When I tell you that his catalogue of hardy plants contains eleven species of New Zealand Acacias and nineteen species of Eucalyptus, you will get some idea of what can be grown there. The garden is on a granite soil, and within the influence of the Gulf Stream, there very narrow. It explains also why many things cannot be grown in England. There are parts of Sussex and Cornwall which are in the same latitude as parts of the champagne district of France, but their soil is not warmed by the sun of France, and so they cannot produce champagne. And this explains also the value of mulching of all sorts; any kind of mulching is simply a device to prevent the radiation of heat from the earth, and so keep warmth at the roots. Mulchings simply act like great coats; there is no real heat in either, but the mulching prevents the escape of the heat of the earth just as the great coat prevents the escape of the heat of the body. I use many devices to serve as mulchings or protections, boards, slates, old casements, bell-glasses, flower-pots, &c., and it is wonderful how very little will suffice. You may see that by the way in which even in severe frosts the ground is often soft under trees and shrubs, and in early autumn you may sometimes see every blade of grass covered with cold dew, while there is none on the Plantains and Daisies. The flat leaves, though comparatively small, are enough to prevent the radiation of heat and so prevent the condensation which produces the dew; but the readiest example is Nature's own beautiful covering of snow. When the snow lies deep and the weather is cold you may send a stick through a thick coating of ice or frozen snow at the top, but below the snow the stick will go into soft ground; and even when the weather is cold and there is no sun, the snow is melted from beneath by the warmth of the earth. In America

a good protection against frost is found in brown paper steeped in sulphuric acid and made tough and waterproof, and a newspaper spread over a plant when frost is expected is often quite sufficient to protect it. I must say something on the

#### AUTUMNAL TINTS

of this year; they were very late and very poor. In my own garden I could scarcely see a single specimen that was well coloured, and in many cases the leaves fell green, or just browned; and in some cases they did not fall at all. This poverty of tints was not at all confined to Bitton. We have in this neighbourhood two places in which very extensive planting has been carried out with a special view to beauty of autumnal tints, Tortworth and Weston Birt. At Tortworth the trees were very poorly tinted, and the gardener at Weston Birt reported to me that it was the same there; and I have in my garden a shrub given to me by the late Mr. Holford, *Euonymus Thunbergianus*, as the shrub which he considered the most beautiful of autumnal shrubs, but this year the leaves are still green in December, and show no signs of colouring. This want of colour may be entirely put down to the want of sun during the summer; leaves require good sunshine to develop their colours as much as flowers do, and that they were unusually late may safely be put down to the frosts of May. The cold weather of the third week in May put back vegetation at least three weeks; and leaves, like the trees they grow on, have their allotted length of life, and if not destroyed by frosts or winds prematurely they run their full course, and if they are three weeks or a month late in the usual time of budding, they will be three weeks or a month late in their decay, especially if their life is prolonged, as it was this year, by a mild October and November. The mildness of these two months was one of the chief climatic features of the year, and the effects in the garden were very marked. On November 30 I noted the following plants in flower, omitting varieties, such as different sorts of Roses, &c. :—

Scarlet and other bedding	<i>Lamium album</i>
Geraniums	<i>Allium glaucum</i>
<i>Datura sanguinea</i>	<i>Oxalis floribunda</i>
<i>Fuchsia globosa</i>	<i>Nandina domestica</i>
<i>corallina</i>	<i>Linum flavum</i>
<i>gracilis</i>	Double <i>Helianthemum</i> s
<i>Ceanothus azureus</i>	Strawberries
<i>Gloire de Versailles</i>	Scarlet trumpet Honey-suckle
Ivy	<i>Lavandula Stoechas</i>
<i>Helleborus niger altifolius</i>	<i>Tropaeolum tuberosum</i>
<i>Borago laxiflora</i>	<i>Erica carnea</i>
<i>Veronica parviflora</i>	<i>multiflora</i>
<i>Rosa polyantha</i>	<i>Pyrus japonica</i>
<i>involuta</i>	Yellow <i>Calceolaria</i>
many hybrids	Yellow Wallflower
<i>Meconopsis cambria</i>	<i>Garrya elliptica</i>
<i>Hydrangea porphyrocladon</i>	<i>Hazel catkins</i>
<i>rosalba</i>	<i>Spiraea Bumalda</i>
<i>Callirhoe involuta</i>	<i>Helleborus fetidus</i>
<i>Achillea umbellata</i>	<i>Lychnis dioica plena</i>
<i>Eryngium creticum</i>	<i>Anthemis tinctoria</i>
<i>Potentilla formosa</i>	<i>Gaillardia</i>
Primroses	<i>Erigeron philadelphicus</i>
<i>Caryopteris mastacantha</i>	<i>Anemone hortensis</i>
<i>Lavatera adsurgentifolia</i>	Daisies
<i>Teucrium purpureum</i>	Coreopsis
<i>Olearia Forsteri</i>	<i>Achillea ptarmica plena</i>
<i>Aponogon distachy n</i>	<i>Ruta crithmifolia</i>
Double Calla	<i>Rudbeckia hirta</i>
<i>Erigeron mucronatum</i>	<i>Campanula Bourgati</i>
<i>Hypericum Moserianum</i>	<i>Portenschlagiana</i>
<i>Convolvulus cneorum</i>	<i>Primula polyantha</i>
<i>Kniphofia triangularis</i>	<i>Nasturtium</i> , bedding varieties
<i>Doronicum cruentum</i>	<i>Geum coccineum</i>
<i>plantagineum</i>	Pampas Grass
<i>Iris stylosa</i>	Red Pentstemons
<i>Cytisus capitatus</i>	<i>Euphorbia Characias</i>
<i>Genista umbellata</i>	<i>Eupatorium riparium</i>
Groundsel	

<i>Geranium Endresii striatum</i>	<i>Solanum jasminoides</i>
<i>Robertianum</i> , red and white	<i>Rubus roseiflorus</i>
<i>Salvia Bethelli</i>	<i>Fatsia japonica</i>
<i>Crocus pulchellus</i>	<i>Hypericum patulum</i>
Dandelion	<i>Aubrietia purpurea</i>
<i>Sida Napaea</i>	<i>Berberis Darwini</i>
<i>Chrysogonum virginianum</i>	<i>Polygonum affine</i>
<i>Abelia chinensis</i>	<i>Hieracium pictum</i>
	<i>Achillea Millefolium</i>
	<i>Cyperus longus</i>

While of fruits more or less ornamental there were the Snowberry, Cotoneasters of several species, *Pyracantha*, Rose heds, Blackberries, *Diospyros tchi-tchi* (this year a fine and very handsome crop, though there were none last year), *Physalis Alkekengi*, *Hymenanchera crassifolia*, *Pyrus Maulei*, and *Iris*, and Holly berries very abundant. I have no fruit on the Hawthorns nor on any species of *Crataegus*, but in the park *Crataegus coccinea* was laden with beautiful fruit, and a collection of the fruit of different species of *Crataegus* was sent to me from Weston Birt, which, for richness of colour and size of fruit exceeded any I had seen before.

Of course I do not mean to say that all these ninety-five plants that I have named were in their full beauty of flower, and many of them were quite out of their right season, but they were all visible on November 30, and that they were so must be put down to the mild weather of October and November, aided, I am sure, by the hot season of 1893.

An interesting question remains: what will be the effect of this season on the future lives of our plants? In all trees and shrubs that are completely hardy the result will be nothing but good; it will be a marked season in their lives and add perceptibly to their size and beauty. But in the case of trees and shrubs that are a little tender we must speak more doubtfully. If the winter should be unusually severe and prolonged, the effect would probably be very disastrous; but if the severity should be only average, I do not think we need have much fear. The abnormal growth may be a weakness, and as a general rule we should say that such a growth in a sunless summer must be weak and sappy, but I think it is not so. The wood, it is true, cannot have been much ripened by the sun, but the growth took place so early in the season, that I think it possible and even probable that the wood is ripened by its own natural growth; and so I look forward to the winter with some anxiety, but not with much fear.

I must now bring my long paper to a close. It has much exceeded the limits within which I proposed to keep it, and if it has too much taxed your patience, I hope that you will draw the right moral from it, and in future years, when you are looking out for writers of papers for your winter session, take Horace's advice slightly altered,

"Præsidentem fugito, nam garrulus idem est."

**Narcissus freak.**—Some three years since when flowering a large batch of *Narcissus* principles under glass I noticed some very distinct from the type. Selecting the most worthy, I ranged them while still in flower, and, numbering them, planted them in due course. In the first year after planting nothing unusual was noticed. Good bulbs were formed, however, and in the autumn of 1894 I planted them in rows side by side. The growth this year has been strong and vigorous, and all the selected kinds ripened and died down much about the usual time, with one exception. Now on July 20 this one, of which I have only four or five bulbs, is as fresh, green, and full of vigour as one expects to see in March or April. There is no sign of ripening in the foliage whatever, a curious circumstance in such

a tropical summer as this, and when the majority of kinds all around have ripened long ago. In very wet, cold, and sunless summers some of the poetical tribe have a tendency to long retain their foliage, but I have had no such experience with any trumpet kind before, and am inclined to allow it to run its course.—E. J.

## GARDEN FLORA.

### PLATE 1025.

#### SOPHRONITIS GRANDIFLORA AND ANGRÆCUM LEONIS.

(WITH A COLOURED PLATE.\*)

#### SOPHRONITIS.

THIS is a small genus consisting of only a few distinct species, *S. grandiflora* being the largest and most brilliantly coloured. It was founded early in the century by Dr. Lindley upon *S. cernua*, the generic name as applied to *S. grandiflora* being seemingly inapplicable. Botanically they resemble *Cattleyas*, and hybrids have been raised between them. None of the species take up much room and all may be grown in small shallow pans suspended from the roof. Three parts of Sphagnum Moss to one of peat fibre will make a suitable compost for them and a very thin layer only is required. They must be kept fairly moist while making their growth, but dislike large quantities of water poured about them, being best dipped in a pail or tank. A mild and airy temperature, rather higher in winter and summer than for the *Odontoglossum* house, suits them well, and they must never be dried during the winter. This latter season is when they usually flower, and consequently the plants must be well nourished, though over-watering is equally injurious. The size of the flowers when compared with that of the growth is remarkable, and as a good proportion of the energy of the pseudo-bulbs must be expended in perfecting these, it is obviously wrong to leave them too long upon the plants. If left and kept in a dry atmosphere the blossoms last five or six weeks in fine condition, but from three weeks to a month is quite long enough to leave them on.

*S. CERNUA* seldom exceeds 2 inches in height, the tiny pseudo-bulbs clustering very closely together and forming a dense cushion-like tuft. The leaves are roundish, about 1½ inches in length, the pseudo-bulbs dark bronzy green. The racemes are short and proceed from the axils of the leaves, each bearing from six to nine flowers about an inch across, bright rose with a yellow lip. A native of Brazil; introduced in 1826.

*S. COCCINEA* is sometimes classed as a separate species, but other authorities make it a variety only of *S. grandiflora*. Both the habit and colour of the flowers vary, some plants having short bulbs and leaves, others being longer, and although some *Orchid* growers affect to pick out the colours by the habit, this cannot be depended on. The flowers of *coccinea* are bright scarlet, and both this and the typical

*S. GRANDIFLORA* are natives of the Organ Mountains, in Brazil. No description of this is necessary, the flower in the illustration being a capital likeness. It is the strongest grower of all, and will thrive with more material about the roots than *S. cernua*. It is none the less truly epiphytic and does much better under than over-potted. Introduced in 1837.

*S. VIOLACEA* is smaller even than the first-named, and although less showy than the others, is, nevertheless, a pretty and pleasing little *Orchid*. The little pseudo-bulbs are slightly

\* Drawn for THE GARDEN by H. G. Moon in Messrs. Sander's nursery at St. Albans, Jan. 15, 1895. Lithographed and printed by Guillaume Severeys.

1874

1. *OPHEODONTIA SPANDELLI* (L.) ALBERTSON & HILL.

swollen in the centre and about 1 inch in length. The flowers are of a delicate soft rosy purple, each 1 inch across, and occurring principally in ones or twos. This is also a native of Brazil: introduced from the Organ Mountains in 1840.

#### ANGRÆCUMS.

That figured belongs to the smaller-growing section of the genus that thrives best in small wood baskets suspended from the roof of a tropical house. They are rather more difficult to grow than the larger habited kinds, but if their wants are anticipated and provided for before they suffer from want of these attentions, they will not be much trouble. In the first place, a lot of close material about the roots must be rigorously avoided, for this means simply death to the plants. The roots in their native habitat, twining about the smaller branches of trees and in similar positions, cannot have anything to surfeit them, but instead are exposed to air and light to an extent hardly possible with those of cultivated plants, and while not advising cultivators to follow Nature too literally, yet to take their cue from her and adapt it to circumstances is the surest road to success. The baskets should have several large lumps of charcoal placed in the bottom, not so loosely as to rock about when moving them about, and the plants should be tied into position. Over the roots a thin layer of Sphagnum Moss is all that is needed, the quantity varying with the strength of the plants and the likings of the various species. The utmost cleanliness is essential, and all decayed portions of Moss or roots should be cut away before placing the plants in position. During the growing season a light shade will be required, but this must be removed in autumn as soon as it is safe to do so; for although Angræcums have no pseudo-bulbs to ripen, yet the leaf system must be consolidated if the plants are to flower freely and pass the winter in safety. Like all distichous-leaved Orchids, the roots of the Angræcums are indicative of the resting and growing seasons, the points greening and getting active in spring and clouding over again in autumn. Thus, it will be readily seen when the supply of water must be increased or diminished, but the plants will not require much drying at any time, nor must the temperature fall below 60° during winter. They are rather subject to the attacks of white scale, these insects frequently appearing in winter while the atmosphere is somewhat dry. In cleaning them the roots that are above the compost must be examined as well as the leaves, for the scale is often to be seen on these, and great care is necessary in its removal. The under-mentioned are all useful free-flowering kinds, the blossoms all lasting a considerable time in perfection.

A. ARTICULATUM is a dwarf-growing plant, with leaves 4 inches or 5 inches long, from the axils of which the flower-spikes proceed. The flowers vary a good deal in shape, and also in the number produced upon the racemes, but all the varieties are extremely chaste and usually pure white. Both this and

A. CITRATUM are natives of Madagascar. The flowers of the latter are small, creamy white, with pale green spurs, and about a dozen of these are produced in two rows upon the horizontal racemes.

A. ELLISI is a pretty, sweet-scented Orchid, named after the late Rev. W. Ellis, who first brought it to this country from Madagascar. The leaves are from 8 inches to 10 inches in length, and it bears long, arching racemes of pure white flowers.

A. FALCATUM is a dwarf plant, with narrow, deep green foliage. The flowers are small and

produced on short racemes. Being a native of Japan, this kind thrives in a much lower temperature than the other species named.

A. FRAGRANS is a very small-growing plant, producing single-flowered scapes, the blossoms being pure white, about 2 inches in width. The dried leaves of this Orchid are called Bourbon Tea by the natives, and are said to resemble vanilla in flavour and scent, and to be used as a digestive medicine.

A. LEONIS (the species illustrated), a native of the Comoro Islands, was discovered by M. L. Humblot. It is a dwarf, but stiff-growing plant, the leaves about 7 inches long and deep green. The flowers are so well drawn as not to need description. This is also known as *Aeranthus Leonis*.

A. MODESTUM is a beautiful little Orchid with bright green, bronzy-tinted leaves each about 6 inches long. The flowers occur in two lines upon the arching scapes and are pure white. It produces its flowers with the greatest freedom.

A. SCOTTIANUM is very distinct and a totally different habited kind. The leaves are terete, 3 inches or 4 inches in length, and produced from a long rooting stem. The flowers, appearing in pairs from the axils of the leaves in summer, are pure white. It is a native of the Comoro Islands, requiring abundance of heat and moisture and very little rooting space. R.

## THE WEEK'S WORK.

### HARDY FRUITS.

PLANTING STRAWBERRIES.—The planting season is now at hand, and my remarks apply to the importance of doing the work as early as possible to secure a strong autumn growth. There are several advantages in early planting on well-prepared ground: the plants grow so freely, and after the genial rains recently, with the earth so warm, the conditions are most favourable. Those who plant early reap a great advantage, as the plants are better able to stand severe frost or drought, and the flower-spikes are thrown up more strongly. There should now be no delay in planting and no stint in the way of food, allowing the soil to settle before doing the work. It frequently happens that land for this crop can be got ready ere this. Ground which has been cleared of early Potatoes, Turnips, Spinach, or similar crops answers well. Much can be done to make poor land suitable by adding heavy soil, marl, or clay if expense is no object, but as in most gardens labour is none too plentiful, the grower by deep cultivation, giving plenty of food, and not allowing the plants to get old or weakened will reap a good return. Firm planting is essential, and in poor land, though deep cultivation is advised, it is not well to bury the good soil. This should be kept on the surface, the manure being placed in layers under it, the bottom soil well broken up with a strong fork and the manure mixed with the middle spit or second course.

PRESERVING STRAWBERRIES.—If fruits for cooking or preserving are required and of small sorts, yearly planting may not be necessary, indeed, some kinds for the above purpose are best left for two years; but as far as my experience goes it is not well to leave them after having borne three crops. Such varieties as King of the Earlies, Grove-end Scarlet, Black Prince, and some of the Pine section are valuable for the above purpose. The plants should now be cleared of the runners not required, and the old foliage may be reduced, the rows well cleaned by hoeing, and a top-dressing of farmyard manure given. This will encourage the formation of strong crowns and large fruit spikes for next season. Where liquid manure is plentiful it may be given freely. The manure placed between the rows should be lightly forked in. It is well to place a line up each side of the plants and cut away a certain amount of top growth, giving room for the manure.

AUTUMN FRUITING STRAWBERRIES.—The plants grown for this purpose should now be allowed to throw up their flower-spikes, which they will do freely if well fed, and the copious rains in most parts of the country will strengthen the flower-spikes and cause the fruit to swell freely. Up to this date vigorous pinching has been necessary to get late autumn fruits, but it is not wise to delay the fruiting longer unless more spikes appear than the plants can mature, when early removal will be beneficial. The season of growth now being so short every means must be taken to forward the crops, and the best food will be liquid manure. The hoe should be plied freely between the rows to keep down weeds, and in heavy soils it is well to place the fruit on slates or tiles, slugs being troublesome. All summer growths must be cut off, and in wet weather should there be too much leafage, some may well be removed to admit the sun.

RASPBERRIES AFTER FRUITING.—The old fruiting canes should not be allowed to remain a day after the fruits are cleared if the welfare of the plants is considered, as these with the fruit crop will have impoverished the plants, and much harm follows when the plants are allowed to make new wood and support the old. Raspberries being surface-rooters will now well repay food in the way of a mulch, and the more decayed the manure the better. Previous to mulching, all useless shoots or sucker growths should be pulled out, and any varieties which appear worn out and are only making a weak growth should be destroyed. The land should be trenched and a new quarter selected for a fresh plantation.

FIGS ON WALLS.—Many trees, no matter how well established, were cut down to the ground level last winter, and, of course, fruit this season will be out of the question. Much, however, may be done towards ripening the wood for next season's crop. Growth in the spring being late owing to the protracted frost, I advised more attention being paid to the new growths from the base, and as much of the old wood or top growth was killed early removal down to a live portion will have facilitated the new growth, as if the new shoots were thinned early, only leaving the strongest, these latter will have made good progress and should now be fastened to the wall to get firm and matured. Avoid crowding the new wood, as if at all soft it will not winter well. Feed freely with liquid manure to encourage strong, rapid growth, and if necessary give a good mulch of decayed manure. Old trees require more moisture than usual this season; having a mass of roots, they will, with less strong wood, send up a lot of thin growths, which must be reduced in number.

CHERRIES—MORELLOS.—The fruit will now be at the finishing stage, and the trees if cropping freely well repay a rich mulch, and plenty of moisture to keep the growths clean and prevent the fruit shrivelling. The Morello does not crack when ripe like the sweeter kinds, and requires much moisture in light land. The trees if they receive a check are apt to go off wholesale; the leaves droop and turn yellow prematurely, and next season the tree, or a large portion of it, collapses entirely. The wood should be laid in neatly, using as few nails as possible. Foreright shoots may be cut back hard, only leaving a few eyes or buds. These will then make good fruiting spurs next season. Should black fly be troublesome, dust some tobacco powder on the affected parts, and, for trees badly infested, syringe over early in the day, so as to get dry by sunset, and apply the powder whilst the shoots are damp. Endeavour to lay wood in freely, as the more new wood that can be laid in, the greater is the freedom from canker.

SMALL FRUITS, such as Gooseberries on north walls, required for hanging, must have the sucker growths cut away, also any lateral or spur growth not required for extension, and, to prevent shrivelling, sufficient moisture to keep the trees free of red spider. Protection must also be afforded by netting or thin tiffany. The latter prevents the fruit being scorched, and also prevents mice or

small birds injuring the fruit. Trees in the open that have borne a heavy crop well repay supplies of food in the way of liquid manure. Any useless growth on bush fruits may with advantage be cut away, as by so doing the trees get more light, and rains reach the roots more readily. Young trees of Gooseberries or Currants planted rather thickly in lines may be mulched with some good manure.

G. WYTHES.

### KITCHEN GARDEN.

**EARLIEST CELERY.**—In some few places Celery is expected by the middle of September, and where Sandringham or any of the early white kinds has been liberally treated since the removal to the trenches in April, a partial earthing may now be given. The first thing necessary is to give the trenches a thorough soaking with farmyard liquid a couple or three days before earthing is commenced, then remove all suckers which may have issued from the base of the plants, also a few of the lowermost leaves. If one man only has to do the work, each plant should be firmly tied together a few inches from the bottom, in order to prevent the soil from getting into the centres. When two men are employed one should walk backwards, grasping the plant firmly with both hands, while the second, walking in the reverse manner, brings up a little soil, pressing it firmly. A small portion should then be taken off the sides of the trench with the spade to give it a level and neat appearance. If any traces of Celery maggot appear, hand-picking must be resorted to before earthing up. Except where this very early demand for table Celery is made, there is no gain in commencing earthing up so soon in the year.

**COLEWORTS—SECOND SOWING.**—A second sowing of this most useful vegetable should now be made, the first batch, which is now growing freely, needing a liberal thinning. Do not neglect this until the young plants through weakness fall about. Encourage the earliest lot by liberal waterings at eventide, so that they will be ready for transplanting as soon as old Strawberry beds are cleared away. My best Coleworts are always produced on such sites, the firm, undisturbed root-run promoting a stocky growth and good, firm white hearts. Plant 15 inches apart all ways, and in dull or showery weather if possible. Watch carefully for underground grubs, these often destroying many of the best plants by cutting them off just beneath the surface. If searched for early in the morning they will generally be found upon the spot. Net the second sowing without fail and keep moist until the plants appear.

**OPEN-AIR TOMATOES.**—The earliest lot of these having now been planted some time will need attention in the matter of securing the leads either to the wires, where the walls are furnished with such, or to stout slanting stakes fixed firmly in the ground. Remove all side laterals as they appear, and in the case of those plants that are plunged in the pots and are showing surface roots, top dress moderately, postponing the heavier mulch and liberal feeding until the first lot of fruit is set. With free cropping varieties it is not wise to allow every fruit in all the clusters to remain, all deformed or secondary ones being removed so that the first set and more symmetrical portion may swell to their normal size. All screens of evergreens, boards or lights may now be entirely removed. Avoid cutting away the foliage wholesale in order to hasten maturity, as this is a positive loss and tends to weaken the plant and lessen the aggregate weight of the crop. Be satisfied with a moderate growth in successive batches, withholding all stimulants for the present. It is not yet too late to plant out later raised batches of good open air varieties, as with a fine autumn an abundant crop may set, which if not ripening on the outside wall may be cut with a portion of wood attached and suspended in a warm dry vinery or greenhouse, where they will ripen sufficiently for cooking or making sauce. This later batch will do best if not turned out of the pots, but plunged as recommended for the first early

lot, being mulched and fed similarly after the fruit is set. Laxton's Open Air is hard to beat, all points considered.

**TURNSIPS.**—Another and final summer sowing should now be made, choosing a cool moist position as recommended for the last two sowings. This will carry on the supply until the August sowings of Orange Jelly and Chirk Castle are made. Should the bulbs attain to their normal size sooner than expected and any fear of a blank occurring exist, they may be lifted and laid in carefully in a cool, shady corner. If this is done in time it is surprising how long they will remain in a usable condition. Turnips now at the thinning stage must get liberal treatment, or grub and hollow or decayed centres may be expected. Give manure water several times and a good bath overhead occasionally in the evenings of sunny days. Thin out well so as to allow of a free circulation of air.

**CABBAGE QUARTERS.**—Some time ago I advised going over the first beds of spring Cabbage and cutting back all the main stems to within a few inches of their base in order to encourage the formation of a colony of tender sprouts at the right date. If this cutting back is not practised, the sprouts come early and at a date when plenty of other vegetables abounds, being in consequence little valued in the kitchen. Secondary lots which have been cut over may now be treated in the same way if the ground can be spared. These will be found invaluable where Coleworts are not grown. Let the ground between the crops be hoed and cleared, and a good sprinkling of artificial manure given should showery weather set in; this will greatly assist the old half-exhausted stems to put forth new vigour.

**RAGGED JACK KALE.**—If a sowing of this hardy and useful green was made when advised, any blank space caused by lifting Potatoes or clearing off Broad Beans and Peas may with advantage be filled with the young plants. This may seem late for such work, but if the ground is in fair heart the plants will make a hard wiry growth and be able to withstand almost any frost, and making renewed growth in spring will afford many dishes and an agreeable change in the dining room. All late-planted Broccoli, Kales and Brussels Sprouts should now be hoed for the last time, and advantage taken of the dry weather to use the same tool amongst all crops again. Sometimes at this particular date a colony of Nettles springs up on Celery ridges; these need timely removal by the hand, using an old glove. Hoing frequently weeds a lot of soil down into the trenches when the weeds are close to the sides.

**HARVESTING ONIONS.**—In all forward districts the earliest autumn-sown Onions will be fit for pulling up. Allow them to remain on the ground for ten days or so, turning them about occasionally to expose each part of the bulb to an equal share of sun and wind, afterwards removing them to a cool dry place and spreading them out thinly. Shallots unharvested should also be got under cover, as heavy rains sometimes cause the bulbs to start into a second growth, which is an evil. As soon as Garlic ceases to grow it should also be treated in the same manner. J. CRAWFORD.

## STOVE AND GREENHOUSE.

### CANNAS AT CHISWICK.

The large-flowered Cannas have grown so rapidly in popular estimation within the past few years and the increase of kinds has been so great that it became impossible for private growers to try them all. The trial at Chiswick will consequently be of great assistance in enabling one to select the finest and most distinct varieties, as it must be admitted that there is a great similarity in many of them. The collection on trial fills the two divisions of the Paxton house, and an early opportunity should be taken of inspecting it, as the plants are now flowering well. The varieties here named and described are a choice selection of the very best, representative of the several types and

colours found in the family. Among the spotted varieties—of which many are not wanted—the finest are Antoine Barton and L. E. Bally, both having good spikes of large, rich yellow flowers, profusely spotted with bright crimson. Mme. Crozy, now fairly well known, is still a prominent variety, and brilliant in effect with its scarlet yellow-edged flowers. President Carnot is a dark-leaved variety, its flowers of a bright self-crimson colour, and Alphonse Bouvier is a striking kind with a long truss of rich self-crimson flowers, fine individually and of telling effect in the truss. J. D. Cabos is one of the most distinct varieties, its stout stems nearly 6 feet in height, clothed with dark purple leaves, and crowned with large erect heads of bloom, the flowers of a bright and most attractive shade of orange-buff without spots or stripes of any other colour. Capucine is somewhat similar in colour to the preceding variety, but much more dwarf in habit, making a robust compact plant with long light green leaves of a decided glaucous tint. Gloire de Empel has dark leaves and extra fine flowers of a crimson hue, and Felix Crousse is distinct, with a free habit and bold truss, the flowers deep crimson, the petals longer and narrower than those of most kinds. Sophie Buchner is an effective variety of strong free growth, its shoots crowned with a noble truss of bright scarlet-crimson flowers that are large and unusually broad in the petal. P. Marguant has pretty flowers of a clear orange-buff flushed with red, a distinct and attractive shade of colour. There are a great many more varieties to be seen, but the cream of the collection is embraced in those here described.

**Arum Lilies.**—Where planting out is practised to secure a batch of strong plants, now is a good time to pot them up, so as to avoid the leaves flagging, as they do when potting is deferred until the last week in September. This dry season has not been favourable for an early growth of the plants. By potting up the roots in good time, and giving them a sunny position afterwards, the lost time may yet be made up. —E. M.

**New Malmaison Carnations.**—I am so far very pleased with the growth in pots of the new Malmaison Carnations raised by Mr. Martin Smith and distributed by Mr. Douglas. They seem to possess all the vigour of the old Souvenir de la Malmaison, Mrs. Everard Hambro', Sir Charles Freemantle and Sir Evelyn Wood being particularly free in growth. While many of the new border and Tree Carnations are of comparatively poor growth, it is pleasing to find these Malmaisons the reverse, as the fine size and colour of the flowers cannot but secure for them great popularity amongst all lovers of Carnations. —J. C.

**Phyllocactus crenatus.**—This beautiful flower should be grown by all. The cottager with his window may command equal success with the millionaire and his acre of glass. The blossoms are large, sweetly scented, and on the inside of a creamy whiteness, which on the exterior petals changes to a darker shade. The flowers are not very lasting, but their loveliness makes amends for their fugitive qualities. Pot in good fibrous loam mixed with lime rubbish and broken potsherds, making the soil as firm as possible. The plant will want no water from November till March, when it will begin to start into growth again. Cuttings should be dried for two or three days before inserting them in the soil. —S. W. F.

**Layering Malmaison Carnations.**—Those who have healthy plants of this popular Carnation will be anxious to increase their stock as soon as the new growths become sufficiently consolidated. In this midland district the old-fashioned plan of turning the old plants into open borders and layering does not answer very well, rooting being very slow and generally unsatisfactory. The plan I adopt is to stand the parent plants on the north side of a span-roofed green-

house, where they are shaded by the foliage of Azaleas and Camellias, sufficient sun and light, however, gaining admission to prevent them becoming drawn and weakly. I then select the most promising shoots, making an incision from one joint to another in the ordinary way. A little Sphagnum Moss is then gently wedged in to keep the incision from closing, and the whole bound round with Sphagnum Moss. The Moss is syringed daily to keep it moist, and in due time the young rootlets may be seen protruding through the bandage in all directions. The layers are then taken off and potted, Moss and all.—J. C.

**Scutellaria Mocciniana.**—A great many members of the genus *Scutellaria* are hardy, but the above-named species—*Mocciniana*—requires the temperature of a stove, or at all events of an intermediate house, though during the summer months it succeeds perfectly in the greenhouse, and, blooming as it does at this season, the flowers remain fresh and bright for a longer period than they would in a warmer structure. This *Scutellaria* is a native of Mexico, from whence it was introduced over a quarter of a century ago, and at one time it was met with far more frequently than it is at the present day. The flowers, which are borne in closely packed terminal clusters, are tubular in shape and about  $1\frac{1}{2}$  inches long, their colour being bright scarlet, with the interior of the bloom yellow. Such a large quantity of blossoms is borne in one cluster, that a succession is kept up for a considerable time. It is easily propagated by cuttings of the young growing shoots put in early in the spring, and kept rather close till rooted, which will not be long. They must not be kept in the propagating case longer than is absolutely necessary, for the plant has a tendency to run up thin and naked during its earlier stages; hence as sturdy a growth as possible should be encouraged, and the plants when young must be stopped in order to ensure a bushy habit. At the same time this must not be carried to excess, for the stouter the stems, the finer the heads of blossoms.—H. P.

**Two forms of *Thunbergia grandiflora*.**—The two distinct forms of this *Thunbergia*, that is to say, the ordinary kind with pale blue flowers and the little-known variety with white blossoms, are just now flowering freely in the Victoria Regia house at Kew, and show well their value for such a purpose. In houses such as this there is ample space to allow the climbers to dispose themselves to a great extent as they will, and it is in this way that subjects like this *Thunbergia* are seen at their best. The two varieties above mentioned form the subject of a coloured plate in THE GARDEN of March 2 of the present year.—H. P.

***Littonia modesta*.**—This is a native of the Natal district of South Africa, and consequently in this country it needs greenhouse treatment, though at one time it was frequently met with in the stove, where the results were often unsatisfactory. The *Littonia* in question is a near ally of the beautiful *Gloriosa superba*, and is a slender-growing climbing plant, attaching itself to any support within reach by long tendrils, which are produced at the ends of the leaves. Both produce curiously shaped tubers, which pass the winter in a dormant state, and in the case of the *Littonia*, slender succulent shoots are pushed up on the return of spring. These shoots soon lengthen and quickly acquire a climbing habit, but they do not attain the length of those of the *Gloriosa*. The flowers of the *Littonia*, which are produced from the axils, are bell-shaped, drooping, and about a couple of inches across. Their colour is bright orange, which is but little represented among greenhouse climbers, and a succession is kept up for a considerable time. Soon after the flowers are exhausted the stems show signs of going to rest, the first indication of which is the leaves turning yellow, and when this takes place the supply of water must be gradually diminished, and finally almost entirely withheld during the winter. Then on the return of spring the tubers should be shaken clear of the old soil and repotted, when they will quickly push up shoots. Care

should be taken that these tender succulent shoots are not injured in any way, as if the growing portion is broken, there will be no flowers from that particular shoot, as it will not break out into growth again, being in fact but a flower-spike.—T.

#### CHLOROPHYTUM ELATUM VARIEGATUM.

THIS plant, I believe, was originally sent out in 1874 or 1875 under the name of *Anthericum variegatum*. At any rate in the latter year I had two nice plants of it, which in time were transferred to 8-inch pots, and therein made good showy plants, the retail price for these extra-sized plants being one guinea each. As a decorative plant it was as a novelty advertised to supersede *Pandanus Veitchi*, but this was never realised. It was also stated to be hardy, a circumstance which resulted in the loss of many plants a year or two later. Indeed, the plant is not sufficiently hardy in some districts to safely pass through our more severe winters even when given frame protection. As a rule, the plant is more generally employed in the cool conservatory or winter garden, and in the latter it is capable of producing a good effect by reason of its well-marked foliage. In many a competitive group, too, in the exhibition tent it may frequently be seen playing its part, either as a raised isolated example or among the lower plants constituting the margin. In all such arrangements, however, the best effect is secured when the plant is slightly lifted up, by reason of the long graceful leaves reaching below the pot containing it. These are some of the uses to which it may be put, but in none of them do we see so much of the natural beauty of the plant as when it is allowed to go its own way.

Quite recently I saw an excellent example of this growing as a window plant in a 9-inch pot. The plant was well furnished and had produced several flowering stems, but these latter not having been removed were fully 3 feet high. Curiously enough, these old flower-stems contributed to the chief attraction of the plant under notice, as from many of the axils on the stem leaf-buds had issued and formed nice young plants. These latter, to the extent of a dozen or more, were thus suspended from the somewhat branching stems in all directions, and in this condition it was certainly one of the most attractive window plants I have seen. I have occasionally seen similar growths on the flower-stems of *Anthericum Liliago*, and more rarely on *A. racemosum*, but not to the same extent as on the plant above noted. Those of your readers who may be in search of a novel and interesting window plant of easy culture could scarcely do better than grow this one, encouraging the plant to flower freely, which it does when established, afterwards leaving it to its own devices. The specimen here noticed was filling quite a large window, and as a variegated plant for this purpose was quite unique. E. J.

***Dipladenia atropurpurea*.**—With the various collectors throughout the world on the watch for new plants it is strange that this *Dipladenia* which was lost soon after its introduction in 1842 should have remained unknown to cultivators till it was re-introduced by Mr. Stephenson Clarke, of Croydon, in 1889, and then it cropped up quite accidentally among some imported *Cattleyas*. It is undoubtedly a great acquisition to stove flowering shrubs, for it will bloom profusely when grown as a little bush, even plants in pots only 5 inches in diameter producing a great number of blossoms. The individual blooms are about 3 inches long and a couple of inches or so across the month, their colour being a kind of chocolate-crimson overspread with a velvety lustre, the inside of the throat orange at the base. The outside of the flower is crimson-purple at the lobes, fading gradually off to the base, where it is almost white. It is one of the most continuous-flowering *Dipladenias* that we have, for even small plants will bloom nearly all the summer. The lover of huge blossoms will doubtless see more to admire in

some of the large-flowered hybrids, but most people would, I think, be inclined to place this species and the white-flowered *D. boliviensis* among the very best of the *Dipladenias*. They are certainly far less particular as to their cultural requirements than many of the hybrid kinds. Both strike readily from cuttings and soon form effective-sized plants. *D. boliviensis*, which was first sent out by Messrs. Veitch in 1870, has flowers rather larger than *D. atropurpurea*, their colour being white with an orange centre. These two species therefore form a direct contrast to each other.—H. P.

***Hæmanthus Katherinæ*.**—Some species of *Hæmanthus*, notably the brightly coloured *H. multiflorus*, often grown under the name of *H. Kalbreyeri*, are not very amenable to general cultivation, while, on the other hand, several of them can be grown with very little trouble and depended upon to flower well. One that ranks high as a good garden plant is *H. Katherinæ*, with large heads of bright cinnabar-red blossoms that last a long time in perfection if they are not kept in too hot and close an atmosphere. It succeeds well in a cool stove or intermediate house temperature, but I have also seen good examples where it has been treated as a greenhouse plant. It has been in flower here for the last month, and forms a very pleasing change from the plants usually grown. A second species that has flowered this year with unusual freedom is *H. albiflos*, whose closely-packed heads of white blossoms are borne on stems about 6 inches high. This is very effective when grown in a large pan, as they grow *H. coccineus* at Kew, for the numerous flower-heads form a very effective specimen. In an importation of *H. albiflos* I have seen very variable leaves, some being nearly smooth and others clothed with whitish hairs. In some of these last the hairs were especially noticeable at the margins of the leaves. *H. albiflos* blooms best when thoroughly established.—H. P.

#### HIBISCUS ROSA-SINENSIS.

THIS, which is known as the Chinese Rose, is regarded as a native of China, but it has been for such a long time cultivated in many parts of the tropics, that it now often occurs in a wild state, and forms a brilliant feature in tropical scenery. It is essentially a stove or at least an intermediate house plant, though during the summer it may be kept in a warm greenhouse. I have met with it in several instances tried out of doors this summer, and in most cases it is flowering freely, though in some places the foliage is not in so good a condition as it might be. At Battersea Park I noted a bed of a single brightly coloured form that yielded a considerable number of its brilliantly tinted blossoms. The different forms of this *Hibiscus* give the finest display when they are planted out in a sunny stove, as they will then flower in the greatest profusion. They strike readily from cuttings, and under liberal treatment will grow rapidly. The typical *H. Rosa-sinensis* was introduced into this country as long ago as 1731, but though some very beautiful varieties have made their appearance within the last half century, it is at the present day to a great extent under a cloud. There are many varieties in cultivation, some with single and others with double blossoms, while one—*Cooperi*—was about a quarter of a century ago very popular as a fine-foliaged plant. The leaves of this are broadly lance-shaped, bright green, irregularly marked with white and crimson. A well-coloured bush of this is very effective. The flowers of this variety are scarlet. No mention of the different forms of *H. Rosa-sinensis* would be complete without a word or two in praise of *H. schizopetalus*, which, though usually spoken of as a distinct species, is at all events nearly related to the old Chinese Rose. It certainly does not possess the large gorgeously coloured blossoms of this last, but it is so distinct from anything else as to be sure to attract a large share of attention when in flower. This *Hibiscus* is of a loose open habit of growth, and, like its allies, will not bloom freely if kept dwarf. As a roof plant it is seen to

very great advantage, for the pendulous blossoms are borne on stalks 6 inches or more in length, and consequently the flowers are brought immediately under the eye. The individual blooms are about 3 inches in diameter, and remarkable for the curiously cut and slashed petals, which are of a bright red colour, marked towards the centre with yellow. As in many of its relatives, the long projecting stigma forms a prominent feature. T.

BOOKS.

DR. SCHLICH'S MANUAL OF FORESTRY.\*

THE present volume is an English adaptation of the well-known "Forstschutz" of Dr. Richard Hess, Professor of Forestry at the University of Giessen. The adapter found it necessary at times to deviate from the original, especially in the chapters on Forest Offences and Rights and Forest Insects, so as to make them more serviceable for English students, and where practicable his examples have been taken from Britain and India. The present volume stands as No. 4 of Dr. Schlich's admirable "Manual of Forestry," leaving only vol. v., on "Forest Utilisation," to complete the series. The adapter gratefully acknowledges the assistance he received from Professor Schlich during the progress of the work, and also from Mr. B. H. Baden-Powell, C.I.E., instructor in forest law at the Royal Indian Engineering College, and late judge of the Chief Court of the Punjab, who undertook the revision of the chapters on Forest Offences and Rights.

Up to comparatively recent times forests were looked upon as the hunting grounds of the great, and little was done in the direction of forest protection beyond what was necessary for securing sufficient tracts of forest for the protection of deer and other game. The barbarous forest laws of ancient times were directed against the unfortunate peasants, whose fields were ravaged by the four-footed lords of the forest unchecked save for the quasi-paternal war levied against them by the feudal lord. The Ban forests of Germany and the forests of Epping, Dean, Windsor, and the New Forest remain as relics of former extensive tracts reserved as hunting-grounds by royal and noble personages. William the Conqueror, who "loved the tall deer as a father," and the other Plantagenet and Tudor kings, whose principal relaxation was

\* Dr. Schlich's "Manual of Forestry." Vol. iv.—Forest Protection. By W. R. Fisher, B.A., with 259 illustrations. Braubury, Agnew and Co. (Lim.), Bouverie Street.

in the chase, and whose sanguinary laws against deer-stealing and minor forest offences were a disgrace even to those times, knew nothing of forest preservation in the broader sense; and in England the first example of a monarch who considered forest trees of more importance than game is to be found in James I. This monarch drew upon himself much unpopularity by enclosing part of Windsor Forest and putting an end to the pollarding of maiden Oak trees, which were lopped in winter to enable the deer to browse off the bark of the lopped branches. None but pollard Oaks have been lopped in this way since 1608, and most of the hollow Oak pollards in Windsor Forest were in existence before that date. The rabbit pest is very badly felt in this royal forest, where they have increased in an alarming manner during the last twenty years, and where large tracts of valuable undergrowth have been

*Gastropacha pini*. Mature caterpillar feeding on the needles of a Pine shoot.

destroyed by them. "Such wholesale destruction," the author observes, "of valuable woods by rabbits would not be allowed in any other European forest." Another cause of forest deterioration was the grazing of pigs and cattle. In old days this was a forest usage second in importance only to that of hunting. In Germany, forest grazing was regulated in 1585 by the Ordinance of Mansfeld, which prescribed a five years' close season for all coppice woods with twelve years' rotation. In 1665 Louis XIV. put an end to the grazing of sheep and goats in the French Crown forests. The custom of grazing pigs in Oak forests has greatly fallen off in importance of late years. The great damage done to forests by insects first attracted attention in Germany in 1780, and since that date important works have been published on forest entomology. Early in 1800 laws were passed in France and Germany for the fixing of shifting sands in the neighbourhood of forests in littoral districts, and to the engineer Brémontier belongs the credit of having been the first to devise a remedy for this cause of forest decay. In 1856 the great damage done by floods in the Rhone valley induced the French to pass a law for the *reboisement des montagnes*. Forest fires, once of frequent occurrence in France and Germany, are now effectively guarded against in those countries. The preservation of birds useful in forestry and agriculture is now the subject of special enactments, but, as the author points out, a serious danger lies in the indiscriminate slaughter by gamekeepers of birds of prey and the smaller carnivora, owing to which thoughtless destruction rabbits and wood-pigeons have increased so enormously, as to become "a veritable scourge to forestry and agriculture, to say nothing of even greater danger from mice and voles."

Lastly, there are the many diseases of forest trees, which researches of comparatively recent date have traced to the operation of fungi.

The book is divided into six parts, of which part 1, dealing with the protection of forests against man, contains chapters on forest boundaries, protection against irregularities in utilising forest produce, offences and protection against forest rights. Part 2 deals with the protection of the forest against game, rodents, birds, insects, with a chapter on insects useful to forests,

Eggs of *Gastropacha pini* on Pine bark.

Pupa of *Gastropacha pini*.

and also special chapters on injurious forest insects (Coleoptera and Lepidoptera). Part 3.—Protection against plants, forest weeds, fungi. Part 4.—Protection against atmospheric influences—frost, isolation, wind, violent rain, hail, snow and rime. Part 5.—Protection against non-atmospheric phenomena—damage by water, avalanches, shifting sand, forest fires. Part 6.—Protection against certain diseases—red rot, white rot, stag-headedness, abnormal needle-shedding, damage by acid fumes from furnaces.

The accompanying illustrations are taken from the chapter on the Pine moth, page 267. This moth (as the editor observes in a note) is fortunately not a native of these isles, but it has played in the history of European forestry a part which entitles it to the bad eminence accorded to it in the present work. A brown moth, 60 mm. to 80 mm. across the outspread wings, with peculiar markings in the wings varying much in individual examples, owes its existence to the interesting specimen shown above. The cater-

Eight-year-old Scotch Pine killed by *Agaricus melleus*. (Reduced.)

pillar attains a length of 80 mm., has sixteen legs, and in colour varies from ash-grey to red-brown or dark brown, with peculiar markings. The moth makes its appearance in the months of July and August, and about 100 to 200 bluish grey eggs, as large as hempseed, in clusters of about twenty-five to fifty, are deposited by it in the bark

crevices of Scotch Pines standing at about the height of a man, or on the needles and shoots of young Pines. In from twenty to twenty-five days the caterpillars appear, and scatter themselves about the twigs where they begin to feed. In October they hibernate in Moss, dead leaves, &c., at the foot of the trunks, and in the following March and April, if the weather is warm enough, they recommence their work of destruction. Pupation takes place in June or the beginning of July, and the moth emerges about twenty days after.

It is a most voracious little beast and the most destructive of all insects to the Scotch Pine forests in Central Europe. It also attacks the Austrian and Mountain Pines, and, if food is scarce, Spruce and Larch too. The attack is on the needles. A single specimen will eat a needle in five minutes and may destroy 1000 needles, and the result of the destruction of the needles and buds is that the tree perishes. The trees may recover, however, if, for a pole, 200 needles and, for an old tree, 400 needles remain green. An attack generally lasts for three, occasionally for four years, until from degeneracy, insect parasites, and bacterial diseases the enemy itself succumbs. Various are the measures taken to get rid of the pest. These include the making of trenches in the ground to catch the caterpillars, collecting the eggs by scraping them from the trees—a method which has the drawback of destroying many ichneumons, collecting the caterpillars after November or by shaking the trees in August, collecting the pupæ in July and August, collecting the female moths in July in the mornings and on cold wet days before the eggs are laid, by which means the ichneumons are not destroyed; but the best and safest plan where the insects have appeared in large numbers is girdling the trees with grease or tar bands. This method was first employed in Silesia in 1829 against that scourge, the *Liparis monacha*. In 1878, in Plietnitz, W. Prussia, 45,000,000 caterpillars were destroyed by means of tar rings at a cost of 7s. per 10,000 caterpillars. In woods under sixty years old the hibernating caterpillars were collected at a cost of 20s. per 10,000. The value of the annual increment of wood saved was 8s. per acre, as against 7s. the cost of the tar rings. The caterpillars, finding their ascent to the tree crowns cut off, return to the ground and try to find their way to other trees; this, however, they are prevented from doing by isolating, by means of trenches, the wood containing the tarred trees from other woods which have not been so protected.

Our second illustration represents the honey fungus (*Agaricus melleus*, L.), one of the commonest in these islands, and the cause of a disease frequently met in conifers. In the accompanying fig. it is seen upon an eight-year-old Scotch Pine, which it has killed. A full description of the symptoms is given at p. 382. Plants which have been attacked eventually die, and when young, generally in the first year of the disease. On examining the dead plant with a microscope the bast and cambium will be found to be destroyed, and the resin-ducts full of hyphæ, and enlarged and deprived of resin; fine hyphæ also proceed along medullary rays towards the centre of the tree. Starch is transformed into turpentine, which flows from the tree. The fungus attacks all indigenous or exotic conifers, especially the Scotch and Weymouth Pines and the Spruce; the Larch not infrequently, but rarely the black Pine. There is scarcely any limit to the great age at which the tree may be attacked, but the disease is most frequently seen in plants between four and fifteen years old. In dense sowings and multiple plantings the disease is at its worst, especially if the wood was originally stocked with broad-leaved trees, as Beech, Oak, Hornbeam, Birch, and species of *Pyrus* and *Prunus*. Left in the ground, the stumps of such trees form the nurseries which propagate the disease. Plants which have been attacked are seldom recognisable as such until the year before they succumb, when their needles turn pale and their shoots are stunted.

The following protective measures are recommended:—

(1) All stumps and roots of broad-leaved trees should be thoroughly extracted before plantations of conifers are established on the site of a broad-leaved wood, and where the disease has once appeared, dense sowings of conifers and multiple planting should be avoided. When the disease shows itself—

(2) All plants which are attacked must be dug up with all their roots and the rhizomorphs and burned. Should this produce a blank, the ground must be thoroughly trenched and all strands of rhizomorphs extracted before it is replanted, and it is best to plant broad-leaved species.

(3) Small isolation trenches should be dug round plants, or groups of plants, which have been attacked, so as to localise the injury and prevent a further spread of the rhizomorphs. The trenches should be far enough from the plants attacked to exclude all rhizomorphs from the healthy trees.

**Garden Flowers and Plants.\***—This little manual is another addition to the series of cheap popular books of which Mr. Wright is the author, and, like those that have preceded it, it contains much trustworthy advice. The book is mainly intended to supplement the instruction that has been given by horticultural lectures under the auspices of the different county councils. It will certainly succeed in this. We note with satisfaction that in his general remarks the author advises simplicity of design and arrangement for the garden borders and beds, always accepting the situation as a guiding factor. A long chapter is devoted to annuals, and if the instructions are followed, the many lovely flowers of this tribe will have a chance to display their true beauty. Bulbous and tuberous-rooted plants form another division, the characteristics and cultural details of these being given, but we regret to see such vulgarisms as the word "bulbarian" (p. 63), which is a disfigurement to the pages of even a cheap book. Bedding plants have a chapter devoted to them, and another follows on the best hardy plants, containing also admirably selected lists of plants for flowering at different periods. We are glad to see these, because in them is the source of true flower beauty for small gardens, as those know well who have seen much of country cottage gardens, always brightest and sweetest when filled with hardy flowers alone. Florists' flowers are the subject of another division, where we regret to see the absurd distinction kept up between Pansies and Violas, and which, apart from its absurdity, will in a book of this kind tend to obscure the merits of the best type of garden Pansy. The book consists of about 140 pages, has a good index, and about fifty simple illustrations of much value, if lacking artistic merit.

## ORCHARD AND FRUIT GARDEN.

### ROOT-PRUNING.

WHILE highly satisfactory results sometimes attend the judicious lifting and root-pruning of old or exhausted fruit trees, innumerable failures have to be recorded through the work being carried out in an unpractical manner. Frequently the excuse for rough and hurried root-pruning is that time cannot be spared for the work, but even where trees are numerous and labour scarce, the difficulty might be surmounted by extending the work over several years, attending first to those needing it most. The old-fashioned plan of digging a trench at a given distance from the bole of the tree, descending to the lowermost roots and severing with the spade great and small together, has had to give way to

\* "Garden Flowers and Plants." By J. Wright. Maemillan and Co.

the more rational mode of lifting all roots worth preserving, shortening those of rampant growth and laying them in near the surface where they can feel the influences of sun and air. Under the old system good results were never obtained, some trees dying outright and others prone to rank growth after recovery from the shock, growing away as strong as ever by reason of the roots being still left down in the cold wet sub-soil. Another great mistake often made is doing the whole of the roots at one time. This to an old deeply-rooted fruit tree often means death or permanent paralysis. When root-pruning is decided upon a sufficient quantity of fresh, sweet soil should be prepared some time beforehand, the same being laid in dry quarters till wanted. Any good loamy compost will answer well, provided plenty of opening material such as old mortar rubble or lime scraps be incorporated. The latter ingredient is imperative, as firm ramming must be practised when the new soil is placed over and amongst the roots. The end of October or beginning of November is a good time for lifting and root-pruning early varieties of Apples, Pears, Plums and Cherries, also Peaches and Nectarines, leaving later varieties until the third or even last week in the month. By disturbing only one half of the roots at a time, the remaining half supports the tree until new fibres are formed, and no serious check is given. When commencing the work the trench or opening should always be taken out at some distance from the tree, as the more of the fibrous portion of the roots that can be saved the better, and many of these are severed when a too close start is made. Young trees that have only been planted a year and which show a tendency to grow too strongly may be lifted bodily and replanted, but any that have stood untouched for several years and have much gross growth ought certainly to be treated in the piecemeal manner recommended for older trees. When this rule is violated, valuable young Pears and Apples are sometimes completely ruined. If the soil is wet and cold, owing to defective drainage, the latter should be rectified, placing a quantity of old brick ends, stones, or similar material in the bottom, and if possible replacing the old compost entirely with new. This need not necessarily be new turf, but a mixture of any fairly good soil, with plenty of rubble as a corrective. In very bad cases it is sometimes advisable to wash the roots previous to relaying them, and the portions of older strong roots that are allowed to remain may be notched at frequent intervals along their entire length to induce the formation of new fibres. Slates or tiles fixed firmly immediately beneath the seat of the tree are most useful in preventing tap roots from descending. It is these that are generally the cause of rank and unfruitful growth in all fruit trees. Mulching after the operation is necessary to protect against frost the newly-disturbed roots, which now lie near the surface and are easily injured by this agent, especially after heavy rains or snow. Rotten manure, however, should not be used, but light, loose material, such as rough leaf-mould. This will allow the moisture to pass away, and what little sun there is during winter to penetrate the border. When the trees operated on occupy warm walls, syringing is needful on fine days for a short time, or until the foliage falls. Some time ago I saw a lot of old fruit trees brought from a state of uselessness to a fruitful condition by the above mode of treatment.

J. CRAWFORD.

**Black Currants.**—The crop of this fruit in the midland counties has been so heavy that poor

prices only have been realised, good fruit having been sold for as little as 1s. 6d. and 2s. a stone. This fact clearly shows that a glut of any hardy fruit benefits none but the consumer, and that a medium crop, from a market point of view, is what is most to be desired. The greater portion of the Black Currant crop hereabouts is past, the fruit having ripened pretty early owing to the drought. In isolated places, and notably in one that has come under my notice, small plantations growing in semi-shaded positions are only just ripening their fruit. This would now realise a much better price, especially if the growers could dele them out to private customers, and thus evade the middleman. The same rule holds good with Raspberries, and it would doubtless pay fruit growers to turn their attention more to the question of aspect with these small fruits, in order to prolong the season and increase the profits.—J. C.

**Leaves for dishing fruit.**—Exhibitors of choice fruits are frequently annoyed at finding their Vine leaves, which looked right enough when leaving home, much withered and not at all suitable for adding grace to the various dishes. There are various substitutes, however, which, independent of their better keeping properties, are quite as ornamental when associated with Peaches or Nectarines, leaves of the Tulip Tree, larger Elm, and Hazel all doing good service in dishing up. Ampelopsis does very well if gathered late the previous evening, and if not wanted for more than one day. Of course, Vine leaves from cool structures, and especially the coloured leaves of some varieties in autumn, stand the ordeal of the show tent far better than from early forced houses, but, as a rule, the above-named subjects answer best. I have also seen leaves of the common Lime used, these, being somewhat hard in texture, lasting well.—J. C.

#### A JARGONELLE PEAR TREE.

SIR PHILIP CRAMPTON was a celebrated surgeon in Dublin, and he resided at No. 14, Merrion Square. In his own profession he was a remarkable man, and amongst the medical men in Dublin to-day there are many traditions of him. There is also a public memorial fountain at the foot of College Street to his genius and worth as a citizen, but by far the most remarkable and beautiful memorial of him is the great Jargonelle Pear tree he planted in front of his town residence and surgery in the year 1815. The tree to-day is one of the features in the square, and the very car drivers point it out to visitors and strangers as a notable thing to see. The illustration is from a photograph by Werner and Son, and shows the tree as seen in its beauty of blossoming early in April last covered with bouquets of its exquisite white flowers. At the present moment every spur and branchlet are thickly set with fruit, and in all its long history this seems to be a record year so far as its fruitage is concerned. As a city fruit tree it is well worth notice, and it is to be hoped that some readers keen of observation as to the beauty and fertility of fruit trees in towns and cities will kindly send to the editor either good photographs or accounts of other noteworthy town fruit trees that may be known to them.

This historical town tree has repeatedly been alluded to in the pages of THE GARDEN, but by far the best and clearest account is that in vol. iv. (p. 417) by the late Surgeon John Hamilton, who in part attributed its fertility and luxuriance to its fibrous roots having gained access to a sewer adjacent to its rooting area. In the year 1873 no less than 1700 Pears were gathered from the tree, but in more recent years this number has been exceeded, more than 2000 fruits having been gathered in an exceptional season. The tree has passed

through various minor cultural vicissitudes. Thus some years ago a zealous and well-meaning attendant, hearing that paraffin oil was fatal to green-fly, and noticing these pests on its young growths, emptied a can of the oil from one of the upper windows, and the result was like that of a fire, the upper branches being dark and bare of leaves for a season or two afterwards. The present owner of the tree (Mrs. Hamilton) is most zealous as to its safe-keeping as a memorial of the past, and she certainly has her reward in now seeing it in a most healthy, fertile, and flourishing condition.

F. W. BURBIDGE.

**Cherry Governor Wood.**—I note "S. W. M.'s" note in praise of this Cherry. It is also my

Jargonelle Pear tree in bloom on Sir Philip Crampton's house, 14, Merrion Square, Dublin.

favourite, outside or in. It is perhaps most at home and most fruitful on walls or fences, but it forms a good pyramid or bush, and I have also planted it as a cordon. But Cherries resent the narrow limits of cordons much more than Apples, Pears or Plums. Under glass or on walls or hoardings with any aspect, even north, side by side with the Morello, the Governor Wood retains the excellency of its flesh and flavour. It is also one of the freest bloomers and surest setters in whatever form grown. Had I only space for one Cherry, that one should assuredly be Governor Wood.—D. T. F.

**Good Raspberries.**—Raspberry Superlative deserves all that Mr. Wythes (p. 40) has said in its favour. The variety Hornet I do not know,

but has Mr. Wythes tried Baumforth's Seedling? While being equal in size and cropping, it is as much superior in flavour to Superlative as Transparent Gage Plum is to the Victoria. It is also quite as hardy and free growing.—F. BEDFORD, *Straffan*.

**Cut-leaved Currants.**—In "A. D.'s" interesting notes on the Chiswick Currants, the White Cut-leaved and Mallow-leaved are described as being very distinct. Perhaps this instructive writer will say whether the Cut-leaved Black Currant is grown at Chiswick and what estimate is formed of its merits. I grew it some years ago and thought it one of the best Black Currants, with a minimum of leaves and branchlets and a maximum of fruit. Neither did I notice Fay's Prolific Red among the best. The Red Victoria is a favourite of mine, and I read with much pleasure that it was still the best late red for walls. I presume the White Crystal and Transparent are bigger and better than the old White Dutch at its best, which is expecting a good deal. It seems singular that more White Currants are not grown for dessert, as not a few say that they are the only Currants worthy of being eaten raw.—D. T. F.

**The Gunton seedling Strawberries.**—I have been glad to see and hear in various directions recently good news of these fine seedlings. From what I have seen and tasted of Gunton Park I quite agree with Mr. Crawford's high estimate of its merit. This writer says of Gunton Park Strawberry that it comes into use when Royal Sovereign is over, is as large as that variety, of a much darker, richer colour, while the flavour is good enough to please even the most fastidious. As a firm, good travelling Strawberry Gunton Park is about the best I have ever handled. Lord Suffield is also a most useful late Strawberry for following on, very fruitful, with stout flower-stems, holding the fruit well clear of the soil. It has a most delicious flavour, equal or superior to The Queen when well finished, rich and almost as dark in colour as Waterloo. Empress of India has probably more of the British Queen flavour than either of the others of this fine trio, and hence it may have been a little less noticed and grown in the same quarters. But this is also a second early in the open, of almost unique merit, and one of the richest flavoured Strawberries under glass.—D. T. F.

**Haphazard pruning.**—I chanced the other day to visit a garden in which the Apple trees showed what mischief can be worked by the knife of an ignorant jobbing gardener. The trees in question were healthy and vigorous bushes about twelve years old, and if left to themselves would have been large and probably fairly fruitful. Summer pruning of a novel and experimental character had, however, evidently been practised for at least three years. This pruning had consisted solely in shortening back a foot or more in June the strong leading shoots; consequently most of the trees were simply thickets, through which sunlight and air could barely penetrate,

the only fruit that was borne being carried on the outer branches. Summer-pruning of a sort should certainly have been practised, but should have been confined to keeping the centres of the trees clear and encouraging the growth of the best situated shoots. It would be far better for those who have not mastered the art and *rationale* of pruning to leave the trees alone rather than mutilate them merely because they think that something, they know not what, should be cut away.—S. W. F.

### RED SPIDER ON FRUIT TREES.

It is not often, luckily, that fruit trees generally are so badly overrun by red spider as they are this season. On all sides are to be seen Apples, Pears and Plums badly affected by this pest, and in a less degree Peaches, Apricots and Cherries are also infested by it. Red spider naturally has done the most harm in the case of heavily cropped, somewhat stunted trees, the leaves on many of these being now of a brownish yellow hue, or more like they ought to appear next autumn. A closer examination of these leaves shows they are alive with the little mites. Peach and Apricot leaves badly infested by red spider will, unless the latter be checked or got rid of, invariably drop prematurely, and if those on the other kinds of trees hold on more tenaciously, they will yet fail to carry out their original functions. A bad attack of red spider means injury, therefore, to both top and bottom growth, and the consequences will be apparent next season as well as during this. It may perhaps be thought that the drenching rains that have fallen lately must have the effect of materially checking the onslaught, and so they have done as far as the exposed upper surfaces are concerned; underneath all is activity, and how to check this is the question. In the case of the larger standard trees, and there are many of these looking very sickly, it is doubtful if much can be done towards getting rid of the spider, though even in some of these instances I should yet feel disposed to see what a thorough soaking of liquid manure would do for them. Anything that will stimulate healthy top-growth to a certain extent acts as an antidote to red spider, and anything that tends to dwarf the tree has a converse effect. Hence the necessity for thinning out the fruit when possible in all cases where there is very much of it and no healthy leafy growth going on. There should be no hesitation about the matter, especially when the affected trees are not large, and this would include wall trees generally. Rains may or may not have been sufficient to well moisten the soil about the roots of fruit trees. The chances are not nearly enough has fallen to bring about this desirable state of affairs, and in any case the way will have been paved for a good soaking of liquid manure to be given. In addition to this something should be done in the way of exterminating as many of the red spider as can be got at. Most preparations, decoctions, or insecticides strong enough to destroy these tenacious mites are also powerful enough to damage the skins of most fruits, and if the skins are damaged, scarring and cracking are the natural result. Too much water will even have the same effect. Syringing Peach and Apricot trees every evening seldom, if ever, has an injurious effect upon the green fruit, but the smooth-skinned Nectarines will not stand it, and if water is constantly or for many hours together hanging on green Plums, these also scar and crack. Syringing Apples and Pears nightly has much the same effect as dull, wet weather after a dry period; it causes the fruit to grow to a large size, but impairs both their quality and keeping pro-

erties, while as regards ripe and ripening fruit of Cherries, Plums, and Gooseberries, these are liable to absorb too much water, and either crack or be otherwise spoilt. The only safe remedy I can suggest is sulphuring the leaves. If a good handful of flowers of sulphur is squeezed through a muslin or canvas bag into a 3-gallon can of soft water, it will mix readily enough, and with the aid of a syringe may be sprayed over the trees. It is the under sides of the leaves that most attention should be paid to, and if one syringing does not deposit a fairly good coating of sulphur on the leaves, a second dose should follow a day or two later on. This coating of dry sulphur sticking to the leaves completely checks the work of the red spider, and it is not long before it disappears. It does not injuriously affect the fruit nor greatly disfigure it, and all the while the sulphur sticks there will be no further trouble. For several years past it has been my custom to sulphur Peach, Nectarine, and Apricot trees under glass directly they are cleared of fruit, and this obviated all further necessity for damping the floors and syringing the trees by way of red spider prevention. W. I.

**Melons Sutton's Triumph and Gunton Orange.**—In these days when new Melons are appearing in great force at each meeting of the R. H. S., one is sometimes inclined to think it is hardly advisable to send more seedlings unless they are something decidedly better than the old-established favourites. For some years I relied solely on Hero of Lockinge and Blenheim Orange, but on losing stock of the first named substituted Sutton's Triumph, and do not wish for a better Melon either for size, depth of flesh, constitution, productiveness, or flavour. A speciality of this Melon is the very powerful perfume, thoroughly ripe fruits emitting a most delicious scent. I was not aware until the other day of any variation in the colour of the flesh, but was assured this was the case; indeed, a comparison of two fruits taken from different plants that were produced from the same packet of seed showed that whilst the exteriors were almost identical, there was a very considerable difference in the colour of the flesh, although the powerful aroma and exquisite flavour were the same in both Melons. Perhaps Mr. Palmer, who was, I believe, the raiser, or the Messrs. Sutton who sent it out, can give a little information as to this peculiarity. For a capital little Melon for a small family commend me to Gunton Orange. There is a great depth of flesh for so small a fruit, the rind being thin, and the receptacle for seed very small. The flavour is all that can be desired, and it is very hardy, free setting, and prolific. In a recent note on the cultivation of Melons the opinion is advanced that the cordon treatment necessitating close planting is partially answerable for canker. This is altogether contrary to my experience; indeed, since adopting the cordon treatment I have not been troubled with this disease, and have attributed it to the ability to get the plants out of the way so much more quickly. There is no doubt that some soils are more peculiarly liable to bring about the disease, and where this is so the plant cannot do its work too quickly. Again, if a big supply is required from limited space there is nothing like the cordon treatment, and a greater number of varieties can be grown in the given space if this is deemed advisable.—E. BURRELL.

**Walnuts.**—It is one of the marked features of this remarkable season that we have (at least, so far as my own observation has gone) a record crop of Walnuts. Not only is there plenty of Nuts, but they are found in unusually large clusters. As a result, we shall see these Nuts very cheap later. It is to be regretted, however, that, remembering what a capital pickling constituent green Walnuts are, far more of them are not gathered and utilised for that purpose.

Had that been the case whilst the Nuts were yet young and soft, not only would the still abundant remainder have been much finer, but the trees would have been materially relieved. It is to be feared that the present season's very heavy crop will necessitate some two years' rest to enable the trees to recuperate and again form fruiting buds. The present crop should, however, largely encourage the planting of Walnut trees. They always form handsome objects if ample room be afforded. They do very well in ordinary soil and are far from being difficult to please. They do well on grass, whether in a meadow, park or orchard. The trees need very little attention after they become well established, and when they are old their wood, if sound, has undoubted commercial value. Probably there is no home-grown Nut so popular as the Walnut. Walnuts are saleable even ere the rind or coat has loosened, although not then too wholesome; but as from that time they may, if well ripened, be kept with care in good condition for several months, there is ample time to utilise a good crop. Besides Walnuts, it is surprising that good small Nuts, Cobs and Filberts are not far more widely planted and cultivated. In too many gardens where these are found they are not cultivated, but rather left to grow wild.—A. D.

### EARLY PEACHES ON OPEN WALLS.

HAVING gathered Peaches from the open walls the second week in July, it may not be out of place to send a note as to their value. Though the varieties are not considered to be all one may desire as regards flavour, I think there will be few complaints, the hot season having just suited the American varieties. Waterloo was ripe in advance of all others, and was most valuable. The fruit was splendidly coloured, the flavour this season being better than in 1893. This variety if treated liberally will be equal to some of the older kinds. Early Alexander is better than ever this season, and though I have no great love for it indoors, it certainly proves a good wall Peach, the fruit being large, beautifully marbled with crimson, and the flavour really good. This was ripe on July 15 on a south-west wall and will furnish good supplies, the trees cropping rather too freely. I only grow three varieties of these very early Peaches, and as they follow each other so closely I have some on a rather cooler aspect than others, thus giving a succession. The finest Peach of the trio is Amsden June. This at times is confounded with Early Alexander, but with me it is quite distinct, the fruit being more richly coloured, not mottled and larger. Amsden June was ripe this year at the same time as Alexander, both having the same position and doubtless both would have been earlier on a full south aspect. A few weeks ago there was an interesting article on this variety in these pages and its value for forcing fully demonstrated, so that it may be termed a valuable addition to our earliest varieties. There seems to be a prejudice against these early varieties in some quarters, and I can understand it to some extent, as without high culture the American kinds are poor, small and flavourless. There must be continual attention from the time the trees are in flower to the end of the season, the ripening of the wood being very important. As these varieties fruit so early it is important that the trees receive a certain amount of attention after the fruits are cleared to keep the foliage clean and ripen the wood. I do not know whether those who cultivate these early American varieties have noticed how small the stones are this season. Of course it is well known that the stones of these kinds are always much smaller than those of the older varieties, but they appear even smaller this year than

usual. This may be owing to excessive heat and drought, and I fear, unless wall trees have been well attended to in the way of moisture and rich mulchings of decayed manure, the fruit will be small.

During the past three years I have tried several kinds of fertilisers when the fruit was swelling, and from careful observation I find much depends upon the season, the kind of soil and the age of the trees. Last season such aids as guano, bone-meal and quick-acting fertilisers were soon absorbed, the season being wet and dull. This year I have found liquid manure very good. Peaches, I feel confident, do not get sufficient food or moisture at times and we hear complaints as to size and quality. The trees revel in a hot summer if well supplied with food and moisture, ample space being given the foliage and the old fruiting wood removed as soon as the crops are cleared. I do not know of any better trees for low walls if well exposed to the south or south-west. I find I get the finest fruits from fan-trained trees on walls 8 feet high. W. S. M.

## ROSE GARDEN.

### MR. GRAY'S ROSE GARDEN AT BATH.

IN a series of chapters that appeared in successive issues of the "Rosarians' Year-Book" Mr. Gray has told us "why he came south," and it was from sheer love of the Rose in its loveliest forms that he moved from the Perthshire highlands to a rocky precipice on the outskirts of Bath and essayed the formation of a Rose garden on a spot that had stricken dismay into the hearts of not a few previous prospective purchasers of the place whose gardening desires were perhaps less keen. To convert an almost inaccessible rocky slope into the Rose garden that now exists could only have been accomplished at enormous cost, but the result is worthy of the labour. These great terraces that have been cut into the hillside now form a unique garden solely devoted to the queen of flowers. Then apart from the charms of the garden itself there are those of the fine situation and beautiful landscape, rich pastures sloping from the garden down to the river Avon, the high hills beautifully adorned with trees on the opposite side. Only by creating a series of terraces was gardening possible, and every bit of stone used was dug upon the spot. These terraces now, having a southern exposure, are perfect sun-traps, and it is no matter for wonder that Tea Roses are happy upon them, especially when all that is conducive to their well-being is duly carried out. The Tea Roses are growing in thousands, and Mr. Gray is even contemplating giving up the Hybrid Perpetuals, which are also largely grown, as the plants, the finest, healthiest lot we have yet seen, do not give flowers of sufficient weight and substance, judging them from the exhibition standpoint. It is solely with a view of growing for show that Mr. Gray has made this garden, and in the day or season when his flowers are perfection they are practically invincible. It follows also that all the Roses grown in this garden are those that give flowers of exhibition merit. With a garden so large and advantageous and a mind so devoted to Tea Roses, we heartily wish that Mr. Gray would devote one terrace perhaps to the Tea Rose as a garden flower, grouping the best varieties thereon, and letting them carry a score of blossoms where to realise the present show standard but one can be allowed. The

show growers produce glorious individual flowers, but the grace and beauty of Tea Roses tossing in many-flowered clusters, filling the garden with fragrance, are other aspects of the flower which we think the most beautiful of all, whilst from an artistic point of view comparison is needless. This, however, by the way, for even the greatest disbeliever in Rose show methods of displaying the charms of the flower cannot but experience a sense of great enjoyment in a garden like Mr. Gray's, where every flower seen is a perfect one of its kind. Maréchal Niel is grown to the extent of some hundreds on walls and in the beds as well, Mr. Gray practising a simple expedient with his standard plants in open quarters of tying out the vigorous shoots horizontally, thus forming a flat, but circular head, magnificent flowers being obtained, shaded and protected by the plants' own leaves. All the best Teas that exhibitors are bound to grow it is almost needless to say were seen in their finest form. Among a few kinds specially noted is La Princesse Vera, conspicuous alike for robust growth as well as for its fine and numerous flowers, which are large, full, of a cream white colour tinged with pink in the outer petals. Comtesse Panisse was very fine, also Perle de Lyon, and Reine du Portugal, though a hopeless Rose in most gardens, was giving good flowers here. Comtesse de Nadaillac puts on its richest tints too in this sunny garden, and Francisca Kruger was so bright and beautiful, that we scarcely recognised it. Jean Ducher, responding to the heat of the year, was a glow of many colours such as only long days of successive sunshine can elaborate out of its great buds, which only in sustained fine weather reach their greatest perfection. Thus might many more be singled out for special mention, especially among the Teas, which appeal to us by special and strongly distinctive characteristics. No mere description in words can do justice to this garden, or adequately express the sense of pleasure experienced. Among many pleasant days spent among Roses there is none that will live longer in grateful remembrance than this. Mr. Gray not only presides over, but entirely manages his own place, and whatever cultural skill his Roses evince, which is considerable, to him is the credit due. Last, but far from least, all Rose lovers are welcome visitors, and ready permission is granted them to inspect the charming spot.

## KITCHEN GARDEN.

### POTATOES.

THE heavy, though so late, rains now falling will not fail to have a very considerable influence on the Potato crop, and already much concern is being manifested as to what that influence might be. At first the moderate showers were credited with a tendency to produce growing out of the young tubers, and it is very likely, so far as not only the earlier varieties not yet fully ripe, or later ones that have had both top and tuber growth checked, that the new impetus given by the rains to growth will produce the growing out anticipated. No doubt in most cases it will be wise to get up the earlier or more matured varieties so soon as possible, as it would be less an evil to have them up good, if small, than to leave them to super-terbate, and thus have a comparatively worthless tuber crop. But already the rain has been so considerable, that the lowest roots have been reached and the soil to fully 1 foot in depth thoroughly moistened. There is no prospect whatever that after such a soaking, should the rain cease (even at the moment of writing), Potatoes will not have ample moisture to satisfy all needs

so long as required. Could we be assured that the rain would stop there, then there would be no doubt but that we should have a very heavy, perhaps an immense, late crop. But once the weather breaks in July, and especially after so long and unusual a period of drought as we have experienced, there is no telling how much rain there may be, or how soon the drought may be turned into a flood. To town dwellers the rain comes as an unmitigated boon; to rural dwellers, and especially to farmers and gardeners, it may be of very mixed value. Thus, if the wet be prolonged, then immense harm will be done to Potatoes and Corn crops, however beneficial it may be to fruit trees and some root crops. In late Potatoes the tendency of prolonged rains, with consequent lack of moisture, will be to promote inordinate top growth with excessive, but late and watery tuber crops; or else we shall see such a visitation of the Potato disease, consequent upon the chilling of the soil and lowering of the temperature, as may be productive of greater loss than would have resulted had no rain fallen for several weeks longer. It seems very probable that those breadths of Potatoes that have ample room between the plants will come off best in any case. Dense planting is still very much an evil, for so many persons do not yet realise the importance of the access of plenty of light and air to the leafage. It is largely through this foliage agency that good sound starchy tubers are formed. A. D.

**Potato White Elephant.**—I know several gardeners who still cling to this Potato for the main supply. The way they treat it to prevent having a crop of much too large tubers is to allow all the sprouts to grow, each root having then half a dozen shoots. The tubers from such growth are naturally much smaller than when the growths are limited to two shoots, as in the ordinary method of cultivation.—E. M.

**The Mushroom house.**—Now is a good time to select a wet day for thoroughly cleaning this structure in readiness for the coming season. Old exhausted beds should be cleared out, all walls whitewashed, and if the presence of woodlice is suspected, boiling water poured on the floors and in all crevices will banish them. See that the heating apparatus is in sound condition and throw open doors and ventilators to thoroughly sweeten the structure. In places where the majority of horses are turned out to grass at this period, manure from corn-fed horses is scarce; therefore, it will be wise if early Mushrooms are required to commence saving it, if even in small quantities, it taking some time to collect sufficient to form a good-sized early bed.

**Small Peas.**—I agree with Mr. Crawford (p. 67) that many small-podded varieties of Peas have very much to recommend them. For exhibition, of course, the small-podded varieties are at a disadvantage, except during the month of May or very early in June when the larger-growing kinds are not ready. This year I grew Cannel's English Wonder for an early supply, and it was surprising what a number of succulent Peas the short pods of this variety yielded. I measured two pods; one barely 2½ inches long had seven fine peas, the other just 2½ inches long having eight peas. I have grown for the last two seasons a variety named Goldfinder, a tall-growing, short-podded kind, but a wonderful cropper and of capital quality. The pods are really crammed with eight and ten peas of a deep green colour. No matter whether grown early, midseason, or late, the crop and quality are equally good. Take, again, Stratagem, a short-podded Pea, but bearing profusely a large quantity of well-filled pods. I have this year grown several of Eckford's newer varieties, and find that many of them are short-podded sorts. He must have had this idea in his head when working to obtain new varieties. Shropshire Hero much resembles Veitch's Perfection in the shape of its pod. It is a free-bearing kind, having seven and eight large peas in each pod. Renown is another well worth attention; the rather short deep green pods are literally

crammed with large peas. Epicure is a taller growing kind, reaching 5 ft. in a season like the present, and bears profusely, some of the pods containing as many as ten full-sized peas. Critic is another variety growing 5 feet high, having quite short pods, but well filled with extra large peas. Essential, again, has short pods, which contain eight and nine peas. Juno grows but 2 feet high, is free bearing; its well-filled pods are short, but contain peas of excellent quality. Several others might be named, but enough has been said to point to the fact that short-podded, free-bearing varieties are becoming more appreciated when they combine these elements and the best of flavour.—E. M.

**Early Cauliflowers.**—In this neighbourhood (South Herefordshire) the season has been a most trying one for many varieties of Cauliflowers owing to the drought and the hot weather, and it is interesting to observe the difference. Snowball was the earliest by a few days, but the heads were so small as scarcely to be worth sending to the kitchen, and they quickly opened out. Early London followed with large close heads, many of them weighing 3½ lbs. when trimmed, and remained in a good condition for some days after they were fully developed with simply one or two leaves bent over them. I think the stock I have had of Walchren must have degenerated, as the plants have been a very poor lot as compared with Early London, and though sown at the same date Walchren was nine days later in coming into use. Defiance produced rather small, but beautifully formed heads, just the size for a gentleman's table, only about three days later than Early London. Several other varieties are so much like some of the sorts named in every respect that I omit mentioning them, as this season can scarcely be considered one to bring out all the good points of any variety, but rather to bring into prominence the bad ones. Provided a true stock of Early London can be procured, I think it second to none as an early variety, sown either in the autumn or spring. Unfortunately, we sometimes get a spurious strain, and in our disappointment are liable to forget how well it has behaved in the past.—W. G. C.

## PUBLIC GARDENS.

### THE VICTORIA PARK AT BATH.

Few provincial public parks are set in such picturesque surroundings or give such commanding views of the landscape as the Victoria Park at Bath. Its beauties alike of situation and those that have resulted from wise planting are exceedingly great. Here on a high hill crest judicious planting and simplicity of design characterise a road which is shaded and sheltered by a long and informal avenue of native trees in rich variety, yet which at the same time allows the eye to obtain frequent glimpses of the valley through which the Avon winds and of the opposite hills. A large portion of the city too, part nestling in the valley and extending far up the tree-adorned slopes on either side, is embraced in this commanding view. Turning to the trees, shrubs and flowers, the most superficial observers cannot be impressed by the beauty of the surroundings. There is very little of that gaudy, showy kind of bedding-out which at its best is a poor and fleeting substitute for the aspects that are only obtained through the use of more or less permanent types of vegetation that happily predominate here. We have often remarked that, instead of filling our gardens and parks almost entirely with gloomy evergreens and funereal conifers, the different forms of native trees should have preference. The common Elm is known to almost everyone, but there are many

varieties that differ in leaf and style of growth, as may here be seen, and although we have met with most of the Elms growing in this park at different times, we have never seen a collection in one place so complete as here. This tree is one of the features of the central avenue, but, happily, is not overdone, Horse Chestnuts predominating in other parts, with sometimes a few Acers, Poplars, and other fine trees which give variety of outline and of leaf growth, not omitting to mention two or three fine Tulip Trees which were abundantly in blossom when we saw them. One of the side walks is fringed with an admirable collection of Thorns, the trees standing on the Grass, and each sufficiently isolated from the next to allow of natural growth. This must be a pretty feature at flowering time, and no lovelier family of trees could be named as being worthy of an important position in a public park. There are noble Sweet Bays here 12 feet to 14 feet in height, and the winter, though it has partly defoliated them, has not cut them back as in many places, whilst, strange to say, Darwin's Barberry has been a much greater sufferer. What was once a grand specimen of *Garrya elliptica* is reduced to a stump by last winter, but one of the best of Evergreens—the Holly—that does well in this park, is represented in its best green, golden and silver variegated varieties. The little lakes have their margins adorned with vegetation in character, two Babylonian Weeping Willows being a prominent feature, also the American Weeping Willow. The golden Elder is here effectively massed, and the Sea Buckthorn gives a charming and restful tone of silver-grey, whilst a little later its shoots will glow brightly with orange-red berries.

### CONIFERS.

The dell is adorned with these, and it was a happy idea to place them here and confine them mainly to this spot. On the Grass slopes they are quite at home, and the specimens of some trees are good. Even the Wellingtonia we could not help admiring, over-planted and over-praised as it has been. Its handsome bole must be quite 4 feet in diameter, whilst its outline is more informal and with less of the sugar-cone shape than we generally see, whilst in colour it is a picture of health—rich green above, silvery beneath, and with none of that rusty tint which so often characterises this tree. Mr. Milburn, who so ably superintends this park, attributes this healthy colour to non-removal of the leaves that annually fall, and now form a thick deposit, which, slowly decaying, without a doubt feed the roots, whose fibres were active, forming a matted growth in the surface soil. A good companion to this tree, and quite as fine, is the specimen of the Californian Redwood tree (*Sequoia sempervirens*). The Weeping Yew (*Taxus baccata* *Dovastoni*) is a feature here, and we have never seen a finer plant. It is really a great spreading bush, with no apparent growth of stem, but situated on a steep slope; its semi-prostrate, weeping branches, luxuriant in deep green colour, cover and completely hide a large piece of ground. A tall and lovely Weeping Birch near is singularly happy, its situation and effect giving a welcome break to the prevailing dark tone. The Weeping Cypress (*Cupressus funebris*) is represented by a very healthy plant, whilst Nootka and Lawson's Cypresses and Thuja gigantea all flourish in the fullest degree. The Pine tribe (*Pinus*, *Picea*, and *Abies*) is admirably represented, and one of the finest bushes of *Daphniphyllum glaucescens* grows in this dell, which, though attractive at all times, must be doubly effective in mid-winter. No account of the trees would be

complete that omitted *Arbutus Andrachne*, one specimen here being very noteworthy. It has a clear stem rising about a yard from the turf, a wide-branched head of long red-barked branches which are conspicuous in colour, and a fine crown of foliage. Other fine trees are the Manna Ash, *Cerasus serrulata*, a specimen planted by Loudon; *Koelreuteria paniculata*, *Pyrus salicifolia*, with delightful silvery leaves; the Kentucky Coffee Tree (*Gymnocladus*), the Maiden-hair Tree (*Salisburia*), *Ptelea trifoliata*, *Corylus Colurna* and the variegated Turkey Oak. Mr. Milburn rather deplored the fact that *Rhododendrons* refused to do well, but if we may judge from what usually happens in most gardens where they thrive, this is rather something to be thankful for, and in consequence we see a park of marked individuality in its tree and shrub life. The latest addition is a department, and an integral part of the park itself, devoted to

### HARDY FLOWERS,

an example that many public parks might worthily imitate. The ground has been thrown into naturally graded mounds, in one place an easy slope, in another steeper, varied with rocks, upon and between which are cushions of Stonecrops, Rockfoils and Houseleeks, with numerous other alpine flowers besides. We were particularly pleased to see that Mr. Milburn had adopted the natural and true way of planting his flowers in simple groups and masses, thereby securing bold and combined effects that are lost by scattering and indiscriminate mixing. For example, in one place we noticed a fine break of Sea Hollies, brilliant in colour and a new revelation of flower beauty to those accustomed to the average assemblage of flowers that appear in public parks. A moist slope in another place was covered with Christmas and Lenten Roses in perfect health and vigour, and the bunch Primroses have a place also. A collection of hardy Ferns is grouped in a spot congenial to them, and a peaty corner elsewhere has hardy Orchids and other peat-loving subjects. *Telekia speciosa* massed on the grass suggested an admirable use for not a few of the stronger hardy flowers. In this hardy flower garden, also, are many choice shrubs grouped or isolated with good effect. *Xanthoceras sorbifolia* was in fruit, also *Elaeagnus edulis*. A spreading bush of *Clerodendron trichotomum*, passing out of flower, will also be a picture soon, with its electric-blue seeds set in their red capsules. *Romneya Coulteri* was flourishing, and *Cesalpinia japonica*, though partially cut back by the winter's frost, strong in growth. Other less rare, but very beautiful, shrubs prominent here were *Spiraea Lindleyana*, *S. arifolia*, *S. japonica*, *S. hypericifolia*, all grouped and flowering together; also the Bladder Sennas, *Olearia Haasti*, *Photinia serrulata*, *Aralia Maximowiczii*, most distinct in leafage, and the Judas Tree. In the grass, too, upon which most of these choice shrubs are grouped, spring-flowering bulbs from Snowdrops to Narcissi are naturalised.

In this park, at least, the season is denoted by the flowers that adorn it, and the garden is full of changing life, which is as it should be, and the aspect much to be preferred to that of the gaudy, monotonous garden that is made for the summer months alone, with its after-legacy of six months' dreary bareness.

**Churchyard Bottom Wood.**—The agitation in favour of the acquisition of Churchyard Bottom Wood, Highgate, has resulted in the Ecclesiastical Commissioners, who own it, making a considerable concession. They will sell the wood

(sixty-five acres) to the district council for £25,000, and waive their right to cut two roads through it. By this the rural character of the wood is preserved, and the Charity Commissioners, who are going to complete their scheme by selling the front for building purposes, will gain another 50 feet frontage, and enable two more houses to be erected upon the land, and thus another £20 a year will be added to the prospective income of the charities.

**New park for Buxton.**—The Duke of Devonshire has presented a valuable site, comprising not less than six acres, to the Buxton town council for the purposes of a public park.

### THE OXFORD BOTANIC GARDEN.

THIS old-established garden, so long and ably tended by the late Mr. Baxter, still maintains its high standard under the care of the present curator, Mr. W. Baker, and when there recently we were greatly pleased to see that the authorities had carried out a much-needed improvement by building an entirely new range of glass houses in the place of the old structures that had served their purpose and outlasted their time. Whilst the arrangement of the garden generally and its outside features are much the same as in years gone by, the renewal and extension of the glass department have afforded Mr. Baker fresh scope, which he has quickly availed himself of, the disposition, arrangement, and healthy appearance of the whole collection of plants being of the most creditable character. Special mention must be made of the house devoted to tropical aquatic plants, which, although not so large as the one in which they are grown at Kew, is not less interesting, whilst the tank being raised considerably above the ground level, the Water Lilies are seen to better advantage, being brought so much nearer to the eye. This tank at the time of our visit was a picture with many flowers, *Nymphaea Lotus* and *N. zanzibarensis* being present in their best and most varied forms. Mr. Baker was also successful in flowering the new *N. Sturtevantii* in this tank last year. Several of the new hardy hybrid Water Lilies were also flowering, but here, as elsewhere under glass, they do not show to such advantage nor attain such noble size as in the open air. Among numerous stove aquatics beside Lilies around the margin of the tank a mass of *Sagittaria montevidensis* was very conspicuous alike in its immense leaves and prettily marked flowers.

The collection of cactaceous plants is a comprehensive one and fills one structure, whilst another contains a good collection of Orchids, and the Ferns, both in number and size of plants, already require more space than the structure allotted to them affords. Other houses contain a mixed collection of flowering and fine-leaved plants, whilst a beautiful as well as a most convenient feature of the new range of houses is a glass-covered corridor that connects them. This is brilliant with flowering plants, *Lonicera sempervirens*, *Plumbago capensis*, *Browallia Jamesoni*, trained Fuchsias and other greenhouse climbers being very gay at the time of our visit.

The old walls that enclose a greater part of the garden are adorned with a host of hardy climbing plants, and although the usual botanical garden method of arranging the hardy flowers in their natural orders is the least artistic way, the beds here contain a large collection, including many of interest and beauty, succeeding each other throughout the season. Trees are quite a feature, as although their number must of necessity be limited, what there are are mostly uncommon and notable representatives

of their kind. The specimen of *Sophora japonica* is exceptionally fine, probably one of the largest in English gardens, its stem nearly 2 feet in diameter, carrying a wide-spreading head of lovely leafage. The Hop tree (*Ptelea trifoliata*) does well and flowers freely, the tree being covered with its curious clusters of winged seed-pods. Another uncommon tree which the winter did not hurt in the least is the Paper Mulberry (*Broussonetia papyrifera*), so called because the Japanese have made paper from its leaves. These are somewhat heart-shaped and rather downy, whilst fruits in abundance on all the branches much resembled those of the Mulberry. There is a very fine tree of the white Mulberry, also one of the best specimens of the Constantinople Nut (*Corylus Colurna*), which fruits freely and was bearing large clusters of its hard-shelled nuts. *Diospyros Lotus* thrives and fruits abundantly, and *Salisburia adiantifolia*, *Virgilia lutea* and *Gymnocladus canadensis* are represented by large and handsome trees. The specimen of *Fraxinus ornus* is a grand one, and must be pretty when in flower, whilst another most distinct Ash is *F. pubescens*, which has very large leaves. The trees of *Pyrus domestica*, *Crataegus Aronia*, *C. tanacetifolia* and the Fern-leaved Beech are all worthy of mention. Among flowering shrubs a group of *Rubus odoratus* was beautiful alike in leaf and flower, and several shrubby *Spiraeas*, notably *S. Lindleyana*, were conspicuous in flower. A shaded border also contains a good collection of hardy Ferns. The inhabitants of Oxford are fortunate in having such a well stocked garden, which is of easy access and open to the public from an early morning hour, whilst the facilities it affords for botanical study must be great.

**Notes from Chester.**—The sprays of *Acer colchicum rubrum* sent will suggest the gorgeous colour effect which is given along the sweep of the avenue in which plants of this beautiful Maple are freely intermingled. The *Hydrangeas* in the shrubberies are distinct and conspicuous. The flowering heads, such as the spike of *Hydrangea paniculata grandiflora* which we send you, set off splendidly a bank of green. The Heaths are always pretty. *Erica vagans alba* is a gem. *Clethra arborea* is not easily surpassed either for flower or foliage, and its beautiful bells are charged with a fragrance that is charming.—DICKSONS.

**Good dry-weather Pansies.**—The present season has not been a favourable one for tufted Pansies, although, in spite of it, we have seen them good in many gardens. At Chiswick recently we made note of several that seemed to be good drought-resisters. The old Duchess of Sutherland was one of the best, and still remains a Pansy of high merit that must not be lightly regarded for the sake of newer kinds. William Niel was charming in its unique shade of rosy mauve colour. Some of Dr. Stuart's new varieties were most conspicuous for healthy growth and abundance of blossom. *Christiania*, cream-white, with rich yellow eye; Sweet Lavender, pale blue; Blue Gown, deeper blue and one of the most persistent; Old Gold, dwarf and neat in habit, rich yellow; *Cordelia*, cream-white; White Wings, of a purer white than the preceding; and Biush Queen were all noteworthy for their vigour, freshness and profusion of flowers.

**Centaurea ruthenica.**—There are several very coarse and weedy *Centaureas* in cultivation that have no merit whatever as garden flowers, and doubtless the presence of these, or the knowledge of their lack of beauty, has served to divert attention from those of the family that are really beautiful. *C. ruthenica* is worthy of a place in the most select collection of hardy plants, and we noted with pleasure at Winchmore Hill, where

choice things in quantity are the aim rather than a few of everything, that Mr. Perry is working up a stock of this species. It is a graceful plant in leafage alone, whilst its pale yellow, long-stalked flowers are handsome and lasting on the plant or in the house. We have seen a good deal of the coarse, but showy *C. macrocephala* in the market this season in a cut state, and if there is a demand for it, *C. ruthenica* would surely be in greater demand if it could be had. A coloured plate of this species was given in THE GARDEN of October 21, 1893.

**The Royal Gardeners' Orphan Fund.**—The usual monthly meeting of the committee took place on the 26th ult., Mr. W. Marshall in the chair. The following special receipts were announced: Wimbledon Horticultural Society, sale of flowers, £5 5s.; proceeds of Rose fair at Croydon, per Mr. G. W. Cummings, £7; Mr. W. A. Miller, Underley Hall Gardens, box, £1 18s. 8d., and Mr. C. Herrin, Dropmore Gardens, box, 17s. 6d. The death of Mr. John Wills, a member of the executive committee, having been reported, the secretary was instructed to convey to Mrs. Wills the deep sympathy of the committee in her bereavement and their profound regret at the loss of so noble a supporter of the fund and of such a sincere and valued friend.

**Kitchen garden walks.**—Where the old practice of using salt on walks for destroying weeds is still adhered to the present is a capital time to renew the dressing. This will ensure clean walks till late autumn, when another and final dressing may be given. Where rains have recently fallen it will be advisable to give all walks another good rolling, this also lasting until October.

**Hand-list of Trees and Shrubs grown at Kew.**—On applying to the agent for Government publications here (Edinburgh) to procure for me a copy of the above, I am informed that it is only to be had at Kew. There must be many persons like myself desirous of having a copy of this useful publication, but as it cannot apparently be had through the usual trade channels, it will be a favour if you will kindly say for the benefit of myself and others at a distance how it is to be had.—F.

**The weather in West Herts.**—July, taken as a whole, was of about average temperature. Owing doubtless to the unusual prevalence of bright sunshine and the heat it had acquired during the preceding month, the soil was considerably warmer than the July mean. During the first half of the month little rain fell, but after this there were very few fine days. The total measurement amounted to rather more than  $4\frac{1}{2}$  inches, which is about 2 inches in excess of the average for the month and greater than in any July since 1880, or for fifteen years. The most noteworthy feature of the recent heavy rainfall was the way in which the rain penetrated the parched ground and the depth to which it descended into it. Indeed, two-thirds of the total quantity deposited has already come through the heavy soil gauge and nearly as much through the light soil gauge.—E. M., *Berkhamsted*.

**Tillandsia Durati.**—In the article upon this plant in last week's GARDEN (p. 49), through a misprint, the word "flower-pot" appears instead of "flower-plot." The passage should read: "Hibiscus syriacus growing in a flower-plot."—W. M.

**Names of plants.**—*Old Subscriber.*—1, *Liriodendron tulipifera*; 2, *Euonymus japonicus aureus*; 3, *Griselinia littoralis*; 4, *Tsuga adpressa*; 5, *Catalpa speciosa*; 6, *Reinospora filifera*; 7, *Spiraea Douglasi*; 8, *Thujaopsis dolabrata*; 9, *Biota orientalis aurea*; 10, *Botula laciniata*; 11, variegated Juniper; 12, *Tilia Molkei*.—*H. Peachey.*—*Rhus glabra.*—*W. H. Cook.*—1, *Lythrum salicaria*; 2, *Relenium pumilum*; 3, *Heliothis patula*; 4, *Epilobium angustifolium*; 5, *Echinops ruthenicus*; 6, send better specimen.—*J. R. D.*—The trumpet Honeysuckle (*Lonicera sempervirens*).

No. 1238. SATURDAY, August 10, 1895. V. I. XLVIII.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHARD AND FRUIT GARDEN.

### MARKETING APPLES.

ALTHOUGH a great deal of information has been circulated by means of the horticultural press, fruit conferences, and other channels on the best mode of marketing fruit, I think little attention has been given as to the best time to market different varieties of Apples to ensure realising the highest value for the same. The proper time to dispose of the Apples is of more importance than many would imagine, and a few notes on the subject may be of interest to those growers who have not had much experience and will shortly be selling their fruit. Taking the earliest varieties first, we have White Transparent, White Astrachan, and White Juneating ready now at the end of July, and I find it pays best to allow each of these sorts to become ripe before consigning to market, a higher price being obtained for them than if sent before that period. As the varieties are soft in the flesh they should be sent in small packages, as, for instance, half sieves or flats, lining these with soft hay or similar material, over which clean paper is placed, and the Apples carefully packed therein, so that no movement of the fruit can take place in transit to market. Devonshire Quarrenden, Cardinal, Mr. Gladstone, Stubbard, Duchesa of Oldenburg, and other varieties of these or Beauty of Bath type that put on a nice colour should not be picked or marketed until the colour is well developed, as the value is considerably increased thereby. On the other hand, Keswick Codlin, Lord Suffield, and Lord Grosvenor are most valuable if sold before they look ripe; buyers in the northern markets will not purchase the three varieties named except at a low rate. I once sent a large consignment away fully ripe, and beautiful to look at, thinking to secure top prices, but the salesman wrote per return that £6 per ton was lost by keeping them until ripe and that his buyers would not give good prices for such Apples, as they kept badly on their hands. But there are exceptions, as, for instance, Golden Spire has always realised a much better price when ripe than earlier; its rich yellow colour and firm skin cause it to travel well and look very attractive when opened for buyers' inspection. The same also applies to Queen Caroline or Brown's Codlin and Ecklinville Seedling. I have sent away many tons of the latter during the past ten years, and have always found them most valuable when fully grown, but they must be packed with great care and in small quantities together—28 lbs. is plenty to have in one package. Frogmore Prolific and Potts' Seedling are somewhat tender in the skin, and should be sold immediately it is seen they have attained a full size. If kept until the Apples assume a yellowish tinge they bruise easily and look damaged when opened; consequently a lower price must be accepted. Yorkshire Beauty and Worcester Pearmain realise the highest value when deeply tinged with red; in fact, all varieties that put on a handsome colour like the two sorts sell well, if of good size, in the manufacturing districts.

The grower must be guided by circumstances with late-keeping varieties like Dumelow's

Seedling, Newton Wonder, Lane's Prince Albert, Bramley's Seedling, and others of that class. My experience is that if £1 or upwards per cwt. can be obtained at the time the fruit is ready to pick, it will pay to send it away at once, thus avoiding the labour and expense of storing and the loss of weight that takes place, for Apples when stored for several months lose considerably in weight. Again, the good or bad crops in America and Canada must be taken into account, as they exercise a very material difference on whether it will pay or not to store Apples largely. Up to the present the Australian Apples need not be feared when put into competition with our own late varieties. From a fair amount of knowledge of prices for late fruit, I believe that Apples worth £1 per cwt. prior to Christmas should realise 30s. per cwt. in March to pay for the extra labour and loss of weight; if more than the latter sum can be obtained, then it pays well for storing the Apples. Sometimes £2 and upwards can be easily secured for these late supplies, but the grower ought to be fairly certain that the supply from abroad will not be heavy, and also that his fruit rooms are adapted for keeping the Apples plump and sound, as shrivelled fruit is a drug and difficult to sell at anything approaching a paying price. W. G. C.

**Strawberry Competitor forced.**—I forced a few plants last year to test its flavour. I had previously seen it in fine condition with a market grower, and was so impressed with it that I gave it a trial. Competitor ripens very quickly, the fruit very large, handsome and of fair quality. When hard forced it is superior to Noble and a better traveller. The potting season now being at hand, those who value large Strawberries would do well to give it a trial. As an outdoor variety it is most vigorous, and does well in a dry season. It requires plenty of space, as if the plants are crowded many fruits are lost.—W. S. M.

**The summer pruning of fruit trees.**—"J. C." (page 60) grasps the force of summer pruning when he says it would be wise not to allow varieties which are prone to make much wood to have their own way in the spring, practising pinching as in the case of pot trees and trees generally grown under glass. Thus sun and air would be able to act beneficially on each shoot and leaf, a thing impossible under the crowding system; and as the more wood a tree makes the more it is inclined to, this early pinching would lessen the liability to grossness and secure a more evenly balanced condition of the tree generally. In other words, the wood would be moulded into fertility through the breaking down of gross buds or shoots into moderate growths, and fully exposing the latter to light, heat and air. But because skilful summer pinching or pruning can do so much, some have pushed it to excess, and by cutting too much and all at one time the cultivator inflicts serious evils on the trees. Summer pruning should be a process running parallel with growth. Nothing could be more unnatural than the way in which it is often carried out, the whole of the current year's shoots pinched, cut, or clipped off at one fell swoop. Can it be any wonder if such sudden and severe arrestment of shoot growths should also stop the supply of food and sap to the fruit, or prevent it ever afterwards attaining to its normal size or developing its best flavour? This wholesale and sudden defoliation of shoots and leaves, this sudden transition from dense shadow to glaring sunshine, is as injurious to the buds as the fruit. Better far go over the trees at intervals extending over a month or six weeks, and thus by two or more easy stages complete the process of summer pruning. The whole matter would also be made very much easier through the stopping of the strongest buds early in the season and the removal of all the weaker shoots bodily so soon as their character was determined. The majority

of those left would then be of that medium and even growth most favourable to the development of fruit-bearing buds.—D. T. F.

**Good Raspberries.**—In a short note on good Raspberries (p. 40) I noted the excellence of Superlative and Hornet. At p. 88 Mr. F. Bedford asks if I have tried Baumforth's Seedling, which he considers superior. Baumforth's Seedling is certainly a good Raspberry, but it is not equal to Superlative, and my opinion is not singular, as in conversation a short time back with a first class hardy fruit grower he told me Superlative was the very best Raspberry grown and the most profitable. It cannot be termed the earliest variety grown, and the fruit is more acid than that of some kinds, but for preserves and tarts the brisk acid flavour combined with the firm fruit is an advantage. I have for years advocated the culture of Superlative in these pages, and for the past four years have planted only one kind (Superlative) on account of its cropping qualities, late bearing, and the few small fruits it produces. Some few seasons ago I had a failure with Raspberries, and, requiring this fruit in quantity, tried Superlative, it being an easy matter to gather 50 lbs. of fruit from a few short rows of plants. In seasons of drought, like 1893 and this year, in our soil Superlative is the only variety I have grown that may be depended upon. Baumforth's may be termed an improved Northumberland Fillbasket, and I have not a word to say against it, but it does not succeed so well on our soil. Mr. Bedford may grow these varieties under more favourable conditions. Again, has he got the true Superlative, as I cannot agree with his comparisons as to flavour? If the long time it crops is taken into account, I consider it the very best Raspberry grown. Given good culture and not allowed to remain too long in one place, it will make grand growths and give very fine fruit.—G. WYTHES.

### GOOD RED AND WHITE CURRANTS.

It is surprising that more attention has not been paid to the larger varieties of Red Currants, such as Cherry and La Versailles, which are superior to the small old red variety so much grown. It may be said that some of the larger kinds do not fruit so freely as the smaller ones, but much depends upon the mode of culture and the soil. La Versailles is a favourite with many who desire large fruit, but it is not liked by all growers on account of the brittleness of the shoots and branches. I have seen it stated that this variety is not worth cultivation, on account of its gross habit and loss of shoots when laden with fruit. This may be prevented by severe pruning in winter, keeping the plants very dwarf, and stopping the summer growth in the fruiting season. By growing dwarfier trees there is less fear of breakage, and it is a simple matter to stop the strong shoots in the growing season; indeed, the main growth may be pinched, and thus reduced in weight. If the weak shoots are cut out there will be less fear of breakage. I do not know of any variety so large as this. On the Continent it is grown under the name of Belle de Fontenay, being much liked for its large fruit and fine acid flavour. This variety fruits freely on the old wood and spurs. If only one large red kind be grown, the choice should be given to the Red Cherry, a variety with many synonyms, and certainly one of the very best. The fruits may not equal those of La Versailles in size, but the crop is little inferior. The plant is of a dwarf habit and of compact growth. Red Cherry is superior to the Old Red, Old Dutch, and the Cut-leaved variety. A few seasons ago I was advised to give La Constante a trial. This must be included in the list of good kinds. It is a large fruit, and much later than any of the kinds named above. The fruit keeps a long time before it shrivels.

There are fewer white kinds, a couple of varieties in most gardens being sufficient. The White Currant is not grown nearly so much, as at one time when glass was less plentiful the fruits were used for dessert. White Versailles is a good

companion to the red La Versailles, the berries large, pure white, with a very thin skin. The White Dutch cut-leaved variety is also very good, bearing well, the fruit of good size and quality; this is also known as Wilmot's Large White. Though a slow grower, it requires to be kept pruned to get fine fruit, topping the trees when in rich land. There are others, such as White Transparent, the berries large and useful for dessert. For walls, Currants are admirably adapted, as the fruit can be so easily preserved from birds.

G. WYTHES.

#### GOOSEBERRIES IN 1895.

IN spite of the drought in many parts of the country the Gooseberry crop has been remarkably good. I am aware in some districts the trees of a few kinds were crippled by frost, but they made such progress during April and May, that its evil effects were soon obliterated. Of course, there has been more trouble than usual with red spider, and complaints have been frequent as to the ravages of caterpillars. Gooseberries in many gardens do not get nearly enough food, and in some none at all. In light gravelly soils the trees soon suffer, and well-known growers of these fruits mulch early, giving rich manures, and to obtain fine fruits lighten the crop. By doing so early in the season there is no loss, as the large kinds are most useful in a green state when gathered early. More attention is now paid to trees that produce large fruits, as these are more valuable early in the season than when ripe. Such kinds as Berry's Early Kent and Whinham's Industry have been extensively planted for early fruit and are a valuable source of income. For private gardens there is an unlimited selection—in fact, too many, and one must not depend solely upon the large kinds if flavour is the first consideration. Again, some of the very large kinds have much thicker skins than the smaller ones, and much of the fruit is lost when the thick skin is taken into account. Some of the very best kinds weep badly, growing close to the ground. Most of the Lancashire prize berries have this habit, and well repay support in the way of a trellis, wall or stakes. I venture to assert that the best varieties when given wall culture are not inferior to the best forced fruits if gathered when the fruits are cool or early in the day. For flavour such varieties as Pitmaston Green Gage, Green Overall, Bright Venus, Harry, Early Red, Early Green, Early Sulphur, Red Champagne, Green Walnut, Red Warrington, Keens' Seedling and Ironmonger will not fail to please, and though not equal in size to some, they may be termed the best where flavour is considered. Those who can devote a north wall to Gooseberries and grow them as cordons, either double or with four shoots springing from the base, will have a nice lot of fruit for a long period. Grown thus, the trees give little trouble when once the growths have made good progress. Of course, much quicker results are obtained from single cordon growths, but I do not advise them, as though they are admirably adapted for training to wires or stakes, they throw out so much sucker growth at the base when planted on walls, that the double cordon is preferable with two or four leaders at about 6 inches or 9 inches from the soil. Grown thus there is little trouble, as the shoots or lateral growths can be kept well spurred back, and the fruits can be readily preserved if the trees are kept close to the wall. In such a position I have never known them to fail, always cropping freely, and if given a good mulch of decayed manure when the fruits have set there is little further trouble, and red spider is not known. The trees like a

cool border, and make very fine fruiting spurs every season. In many gardens there is often vacant wall space which could be utilised, and it would well repay to renew the bushes more frequently. Young trees are better able to resist extremes of weather and give much finer fruits. In planting it is well to get the ground into condition early in the autumn and plant just as the leaves have fallen. Unless grown for exhibition, some half-dozen kinds of each section are sufficient.

The best varieties this season with me on poor soil have been Whitesmith, King of Trumps, Aline, and Lady Leicester, all white varieties—the best reds being Conquering Hero, Forester, and Rough Red. Among the yellows, Leader, Drill, Tiger, Trumpeter, and Early Sulphur are the best, the green kinds being Green Gascoigne, Green Overall, Surprise, Stockwell, Keepsake, Telegraph, and Berry's Kent for earliness. This is a select list, but out of hundreds to select from it may be relied upon. It includes early and late varieties, not fastidious as to soil, and good croppers.

G. WYTHES.

#### SEASONABLE VINE NOTES.

If wasps' nests are as numerous generally as they are in this part of Herefordshire, Grape growers will be greatly troubled by these pests. In one field of twenty acres over eighty nests have been destroyed by the aid of cyanide of potassium, and yet they appear as numerous as ever. Fortunately there are means of preventing the wasps doing very much damage in vineries and other fruit houses without enclosing the fruit in muslin bags, which I saw being done recently. For a number of years I have relied upon Davis's wasp destroyer to keep the enemy at bay with the most gratifying results. Immediately the wasps commence to attack the fruit, a little of the liquid is dropped into the berries that have been eaten; in a very short time it will be seen that any wasps visiting the doctored berries are in difficulties; some roll off the berries and drop on the floor, others manage to fly a short distance, while a few may pass out through the ventilators, but in every case a peculiar buzzing sound, which seems to alarm all their fellows in the vinery, is made by the wasps. By a little perseverance in tainting the berries that have been damaged, wasps will avoid the vinery and do practically no harm. Personally I have not lost a bunch since using the destroyer. A word of caution is necessary in using this mixture. A strong warning should be given to young hands not to eat or touch any of the Grapes, neither should the bottle containing the mixture be carelessly left about. Only a short time ago there was a very painful proof of the poisonous nature of the above, and accidents frequently occur through the carelessness or want of thought of people who are well aware of the great value of these poisonous mixtures when properly employed.

Insect pests, including the dreaded mealy bug, are a source of great trouble and annoyance to many gardeners in those establishments where plants have to be grown in the vineries, but I think brighter times are in store for that class of men, and I believe they will have less cause for worry in keeping the Vines and Grapes free from mealy bug. I am thankful to say that bug never got a footing in vineries under my charge, but I have had trouble from it in plant houses, and of all the many insecticides in the market, I have only found one that will destroy this pest by fumigation, viz., the X L All Vaporising Fumigator. I saw a late vinery in which the Grapes were changing colour a few

days ago that had just been fumigated with the above at double the strength recommended by the makers. So far as I could see, no injury had been done to the fruit or foliage, and the mealy bug lay in quantities dead on the paths, staging and elsewhere in the vinery, and after a careful examination of the Vines and plants, not a living bug could be discovered. Whether it would be safe to fumigate Vines bearing ripe Grapes is a matter that possibly some reader who has tried it may answer in the negative or otherwise.

Where all the Grapes have been cut out of the early vineries, much may now be done towards increasing the crop and size of bunch next year. If red spider or thrips has been prevalent, the leaves may be thoroughly syringed with a safe insecticide, afterwards giving plenty of clean, soft water overhead daily while the foliage remains green, and if the border is porous with free drainage, liquid manure can be given with decided advantage up to the time the foliage falls, and on some soils that are of a specially hungry character, such as the one I have to deal with, feeding after the leaves have fallen will prove highly serviceable. When the Vines have been cleared of their crop, I think it a great mistake to allow a fresh growth of sub-laterals to weaken the back buds and to some extent diminish the light they ought to have at this season. A few gardeners contend that by allowing this late growth, a supply of stored sap is acquired by the Vines, causing them to break strongly and more evenly when started again. Such a contention I question, as it is more probable that instead of stored sap there is a lot of wasted energy, and the Vines do not rest so soon or well as they ought to do if first-class results are to be obtained.

#### THE ROCK GARDEN.

##### XII.

THE first half of July has been a time of brilliant sunshine, and though at present cloudy and rainy days prevail, the earliest part of the month was all that could be desired with regard to favourable weather for the rock garden. Mountain flowers, naturally, are not quite as abundant during July as they were in June, but among the plants blooming in July there is nevertheless a great number of beautiful kinds well worth the attention of those whose rock gardens, as a rule, are almost bare of flowers directly after the bright spring flowers have faded. Many plants mentioned in my previous notes as being in bloom during June are not only still in flower, but are even more gorgeous now than they were a month ago. Especially is this the case with Marliac's new Water Lilies, which flower most abundantly wherever planted. As I have already mentioned these in a previous article, I will pass no further comment on their exquisite beauty. I planted six varieties of the new Nymphaeas in the rock garden at Abbotsbury, where they were covered by scarcely more than a foot of water. They have not only not suffered in the least during the last severe winter, but made splendid growth and have been flowering continuously since May, quite dispelling the erroneous assumption still frequently met with that Nymphaeas should not be grown in water less than 6 feet deep. I may here also mention a few handsome plants growing not in, but near the water, which were in full bloom early in July. *Parnassia palustris*, with its white flowers on long stems, is an excellent companion to *Saxifraga aizoides*, with yellow flowers, as both flower at the same time, and love abundance of moisture and full exposure to the sun, while the deep yellow *Saxifraga Hirculus* and

the lovely *Cypripedium spectabile* love peaty soil and a half-shady position. Tall plants by the waterside blooming in July are the graceful *Spiræas*, *S. palmata*, *S. p. alba*, *S. Ulmaria*, *S. U. picta*, *Astilbe rivularis*, and also the effective purple *Loosestrife* (*Lythrum Salicaria superbum*), whose flowers form a capital contrast to the various yellow tints of the many *Hemerocallis* still in bloom.

#### DWARF ROCK PLANTS IN BLOOM DURING THE EARLY PART OF JULY.

The season for choice gems in the select part of the rock garden is by no means over. Some of the prettiest things out in bloom early in July were *Acantholimon venustum*, *Dianthus Freyni*, *Potentilla nitida*, *P. n. atrorubens*, *Umbilicus spinosus*, and *Androsace Chamæjasme*. *Dianthus Freyni* is a rare and beautiful Pink of dwarf and compact habit. Its flowers somewhat resemble those of *Dianthus glacialis*, but they are larger and the growth also is a little stronger than in that variety. It does well in a narrow fissure filled with calcareous soil, and has flowered abundantly at Exeter. *Acantholimon venustum* is also still rare, and not nearly so well known as it deserves to be. It is very different from and superior to the much better-known *Acantholimon glumaceum*. Its stiff prickly foliage is best compared to a minute *Yucca*, about 3 inches or 4 inches high, and bearing a spike of crimson flowers on an erect stem 6 inches to 8 inches high. *Potentilla nitida* with its carpet of silvery leaves and large white flowers is a most attractive plant. The white flowers often sport into a shade of pale pink or flesh colour, but all are eclipsed by the dark crimson variety, still rather rare and known as *Potentilla nitida atrorubens*. Of *Primulas* I noticed the following were in bloom early in July, and some of them are still flowering now. *Primula Poissoni*, *P. magellanica*, and *P. capitata* are all doing remarkably well in a half-shady position. *P. Poissoni* is similar to *P. japonica* in shape, but its rosy crimson flowers are borne on a shorter spike. *P. magellanica* is not unlike *P. farinosa* in its flowers, but the plant is more robust in all its parts, and being of the easiest cultivation is a very desirable plant for the rock garden. *P. capitata* is very striking with its heads of lilac-purple flowers on long erect stems, and is especially attractive when planted in large groups. The *Gentians* form another attractive feature in various rock gardens in this county, and especially at Exeter, where *Gentiana cruciata*, *G. septemfida*, *G. Kesselringi*, *G. thibetica*, *G. decumbens* and *G. asclepiadea* were flowering together early in July. Perhaps the most striking of the group is *G. Kesselringi*, with flowers of a much paler azure-blue than in most *Gentians*. *G. decumbens*, also, is of a paler hue than the semi-prostrate deep blue varieties *cruciata* and *septemfida*. *G. thibetica* is much taller and has a head of white flowers, which, however, seldom open profusely. *G. asclepiadea* is also rather tall, growing 1½ feet or 2 feet high and bearing numerous purplish blue flowers, produced from the axils of the leaves. These *Gentians* form an admirable succession to the spring-flowering varieties now past. Two excellent plants suitable for planting sideways into an abruptly sloping or vertical fissure are *Carlina acaulis* and *Horminum pyrenaicum*. The former has very large creamy white flowers and requires a sunny position, while the latter has a spike of purple flowers and does best in the shade in a position similar to that frequently recommended for *Ramondia*. Many of the *Campanulas* mentioned in my notes during June are still blooming profusely, but one of the dwarfest

and choicest newly opened is *C. Waldsteiniana*, which is of very neat habit and well worthy of a place among the select plants. Of taller *Campanulas* still in bloom I will only mention *C. Hendersoni*, *C. Burghalti* and *C. lactiflora*, while those of medium size now blooming include *C. Hosti*, *C. linifolia* and *C. Scheuchzeri*, all of which make excellent rock plants if kept sufficiently far away from the smaller kinds of mountain plants. *Haplocarpha Leichtlini*, also, is still flowering profusely, and on a dry rocky ledge *Opuntia Rafinesquiana* is expanding its large yellow blossoms after having withstood the exceptionally hard frost of last winter. The pink-flowering *Mesembryanthemum uncinatum* has also survived and is covered with blossoms; while close by *Silene Schafta* is expanding its graceful shoots laden with bright crimson flowers. The deep blue *Platycodon Mariesi* is also now at its best, and as in winter it dies down altogether, it never looks so well as when planted in large groups and displayed on a carpet of dwarf Evergreen plants like *Herniaria glabra* or others that would cling closely to the ground.

#### CARPETING PLANTS BLOOMING EARLY IN JULY.

I have often pointed out the importance of carpeting plants, not only for covering the ground between medium and tall sized plants, but also for being planted by themselves, falling over stones, often in places where no other form of vegetation would be equally effective. *Lippia repens*, though severely cut in some places by the frost, has survived the winter in Devonshire, and its pink flowers, just now nestling on dense greenery and clinging closely to the rock, are most attractive, as are also the white flowering *Pratia angulata* and the exquisite little *Hypericum cuneatum*, *H. repens* and *H. nummularifolium*, all with yellow flowers and of very neat habit. An excellent plant for quickly covering a stony ledge is *Umbilicus chrysanthus*. Like the *Umbilicus spinosus* already mentioned, its leaves form pretty rosettes, but are less incurved and without the spiny apex. Moreover, *Umbilicus chrysanthus* grows rapidly, while the other variety increases but very slowly. The flowers are pale yellow and appear here early in July, but on account of the pretty evergreen rosettes, the plant is an ornament to the rock garden throughout the year. It requires a dry, sunny position. Among the carpeting plants flowering in early July I would also mention a few varieties of *Sedum*. Even the common *Sedum album* is not to be despised in the rock garden, for its evergreen foliage and bluish white flowers are most suitable for bold effects, and as it grows very rapidly, it should be allowed to cover a large patch of ground in places where quick growth is desirable, and where no harm can be done to choicer plants of slower growth. The same might be said of the yellow flowering varieties *S. Bridgianum* and *S. Midden-dorffianum*, but their dark foliage does not form so dense a carpet as that of the former. *Sedum spurium* forms an evergreen carpet studded with heads of pink flowers. *Sedum crassifolium* should be in every rock garden. All through the winter its very bright green glossy leaves were most ornamental, and when in July a mass of golden yellow flowers is added to the display, few things in the rock garden are more effective, especially for distant effect. Of other pretty carpeting plants flowering during early July I will only mention *Convolvulus lineatus* with silvery grey leaves and large pink flowers, *Arenaria grandiflora* with numerous white flowers, and *Arenaria caespitosa aurea* with a dense carpet of golden yellow leaves studded with white flowers.

#### MEDIUM-SIZED AND TALL PLANTS FLOWERING DURING EARLY PART OF JULY.

Among medium-sized plants suitable for prominent ledges in the bolder part of the rock garden I would mention the lavender-blue *Statice*, such as *Statice elata*, *S. Gmelini*, *S. bellidifolia*, *S. spatulata*, *S. elata* and the bold *S. latifolia*. A mass of the yellow *Helenium pumilum* might also be used with good effect, and not less striking are well-arranged groups of *Lychnis Haageana* with its large showy flowers in various shades of red and the beautifully fringed *Lychnis Flos-cuculi plenissima*. Very pretty, too, is a group of the dwarf yellow *Solidago nana compacta* contrasted against the mauve *Erigeron alpinus*, *E. glaucus* or the crimson-purple *Prunella Webbiana* and its white variety. The dark blue *Delphinium cashmerianum* and the pale yellow *Scabiosa Webbiana* form another good contrast. A very handsome plant of medium size is also the orange variety of the Welsh Poppy (*Meconopsis cambrica*), and in a moist half-shady spot *Spigelia marilandica* is conspicuous by its red, yellow-tipped blooms. A charming white flower is *Anthemis macedonica*. The fine specimen on Messrs. Veitch's rockwork at Exeter was killed by the severe frost, but the plant had seeded itself and the seedlings are already in bloom. Among tall plants in the background of rock gardens few things are more imposing than a good specimen of *Centaurea macrocephala*, with its bold foliage and large yellow flowers. *Telekia cordifolia*, another noble plant, is more in its place as a single specimen on Grass near the rock garden than among the rocks themselves. *Romneya Coulteri*, too, is now developing its large white flowers and doing well in a well-drained position at the foot of a large rock. *Tropaeolum speciosum* is flowering most abundantly at Newton Abbot, where it covers a large rock.

In conclusion, I would mention a few effective tall plants very suitable for a border adjoining the rock garden: *Liatris spicata*, *Chrysobactron Hookeri*, *Physostegia virginica*, *Coreopsis lanceolata*, *C. grandiflora*, *Cimicifuga racemosa*, *Heliopsis patula*, *Rudbeckia laciniata*, *Bocconia cordata*, *Harpalium rigidum*, *Lychnis vespertina alba fl. - pl.*, *Eryngium Bourgati*, *E. giganteum*, *E. alpinum maximum*, *Chrysanthemum filiforme*, *C. S. Sage*, *Monarda didyma*, *Aconitum pyrenaicum*, *Potentilla Hopwoodiana*, *Helenium striatum*. All of these are among many others blooming early in July and most effective.

F. W. MEYER.

Exeter.

(To be continued.)

## ORCHIDS.

### NOTES ON PHALENOPSIS.

THESE are still growing freely, and are apparently making a solid and satisfactory progress, the weeks of bright sunshine allowing of ample ventilation without lowering the temperature unduly. When one sees how well this free circulation of air suits the plants and notes the robust character of the foliage grown under these conditions, it seems hard to have to close the ventilators and practically to keep them so for several months. Yet this is what we must do later on in the season, and if the plants are to come through the ordeal safely they must have the best of attention now before any fall in the outside temperature occurs. With these beautiful Orchids all changes of temperature or other atmospheric conditions must be brought about gradually and naturally, and it is quite

time that the shading was diminished to a certain extent, leaving it up a little later in the morning and removing it earlier in the afternoon. Healthy well-grown *Phalænopsis* will stand more sunshine than is usually supposed, and at this season the blinds must not be kept down for five minutes longer than is absolutely necessary. I know well the difficulty too often experienced by Orchid growers, where, owing to the miscellaneous character of the plants grown in one house, it is impossible to give any one family the most suitable treatment; but these beautiful Moth Orchids seem to me to stand out from all others and claim a larger share of attention than any. With these there is no pseudo-bulb to finish up, as with a *Dendrobium* or *Cattleya*, nor a growth to complete like that of a *Cypripedium*, for as often as not the plants when going to rest have a leaf half made. Still, a watch must be kept on the plants notwithstanding, and an experienced grower will be quick to note the steady, so to speak, of the growth which is precursory to resting. When this occurs he will know it is high time to slightly diminish the atmospheric moisture and allow a little more sunlight. It is at this season when the advantage of a broad spacious house, where ample ventilation can be given without drying up all the atmospheric moisture, will be apparent, and for *Phalænopsis* there is no comparison between the two styles of house. While not advocating a system of drying the plants at the roots, I always like to make them look for their moisture at this season and let them get a little on the dry side always before watering, and at least once a week to leave them a few hours quite dry. Some may be inclined to question the advisability of this, but I have practised it with such good results, even with small and weak plants, that I do not hesitate to recommend others to do so. Of course it is only a detail, and I do not wish to lay undue stress upon it, the chief point after all being to build up a firm and well-consolidated growth, foliage that will not disappoint us by falling off wholesale in winter and render the season's growth useless. The real importance of this will probably only be grasped by beginners after a season of ill-luck, when after growing them well, as they think, they find themselves at their wits' end to know what is the matter with their plants. Now, however, is the time to prevent this by avoiding exciting the growth, making the foliage soft and susceptible to changes of temperature, no matter how slight. Let the plants have their way and do not attempt to force them either to grow or rest, but observe them closely and take the precautions noticed above when seen to be necessary. In dull weather keep a little heat on the pipes to prevent a sudden drop in the temperature, but always make at least 5° difference in this between a fine and a dull day. The night air must be reduced unless the house stands at or about 65°, but it is not wise to let it rise much above this, especially with fire-heat. The house must be ventilated on top as soon as 70° is reached, and 5° above this must be the maximum now in dull weather, running up to 85° or 90° with sun-heat at mid-day.

H. R.

***Dendrobium thyrsiflorum*.**—Several plants of this species have behaved in a rather singular way this season. They have produced a number of secondary spikes, but have not as yet started to grow. This I attribute to a slight check given the plants owing to removal, and partly also from being grown in too much heat, viz., with the warmest section of the genus. I have usually grown these with the *Cattleyas*, but from force of circumstances had to arrange them in a very

warm house. I can think of no other reason for their doing so, as the plants appear quite healthy, and last season made a splendid growth.—R.

***Cypripedium Sedeni candidulum*.**—This, one of Messrs. Veitch's hybrids, is a most charming kind and almost constantly in flower. A strong plant that had been flowering all through the late winter and spring months was cut over about three weeks ago, and now several more spikes are appearing in the last formed growths. The blossoms resemble those of the type, but are lighter in colour, this form having been raised by crossing *C. longifolium* with the white form of *C. Schlimi*.

***Cattleya Eldorado virginialis*.**—This name is used to describe the albino form of this pretty *Cattleya*, which is now in flower. The sepals and petals are pure white, also the lip, the only colouring being a blotch of deep orange in the throat. The plant is a native of Rio Negro, and although not a very robust grower, it thrives well under ordinary *Cattleya* house treatment. It must not be over-potted and the compost should be free and open. It is also very suitable for basket treatment.

***Warszewiczella Wendlandi*.**—The flowers of this charming Orchid are large and very attractive. Each measures upwards of 4 inches across and is pure white, excepting the purple blotch on the lip and a few markings on the crest. Having no pseudo-bulbs, this species requires very careful treatment, especially during the winter months, for the plants must be kept at rest and yet must not be over-dried. A thin compost (one that soon runs dry after being watered) is the best and preferable to block treatment, which is undoubtedly too poor for them. The plants soon show the effect of too little or too much water, the former causing the foliage to wither and drop off, the latter often tending to spotting and decay. I have found it thrive best in a shady corner of the *Cattleya* house.—R.

***Phalænopsis violacea*.**—This very distinct and charming little species I recently saw in good condition. The blossoms were about 2 inches across, the sepals and petals light yellow at the ends, becoming towards the base a rich violet-rose. The lip is also purple with a yellow crest. The flowers last a long time in good condition and are very sweetly scented. It is a good grower, thriving well with the other species. The leaves are broadly lanceolate, about 9 inches in length, bright green. It is a native of the Malayan Archipelago, was introduced in 1861, and has several well-marked varieties.—R.

***Aerides quinquevulnerum*.**—This superb *Aerides* resembles *A. odoratum*, but is easily distinguished by the five segments having a purple blotch on each of them, it being from this circumstance that it obtained the specific name. The fragrant and pretty blossoms are produced at various times, but usually towards the end of summer, and last a considerable time in full beauty if not wetted or bruised. It is a strong grower, thriving well in pots or baskets, in Sphagnum Moss and charcoal. The best time to repot is early in spring, just before growth commences, and when giving fresh compost it is just as well to give as much room as the plants will require for three years at least, as they dislike disturbance at the root. I like to grow these plants in the ordinary flower-pots of a suitable size, as when the time comes to repot one has only to carefully break them, and the roots may go into the new ones almost entire. None of these large-growing, distichous-leaved Orchids like to be crowded in the houses; each plant should stand well clear of its neighbour, and the larger and more spacious the house, the better the plants will thrive. The atmosphere must be kept moist and charged with ammonia, and the plants must not be dried at the roots at any time. *A. quinquevulnerum* is a native of the Philippine Islands and Manilla, having been introduced in 1838.

***Cattleya crispa*.**—This species was introduced from Brazil to our gardens some sixty years ago, but although very beautiful, and particularly useful

as an autumn bloomer, its merits appear to have been completely ignored in the race for novelties. It would be well if fine forms of this plant were searched for; it not only greatly resembles *Lælia purpurata* in growth, but it may with justice be called the autumn-flowering *purpurata*. It requires a severe, but judicious rest to induce it to flower freely.

#### DISA GRANDIFLORA.

THIS Orchid is now in flower in many collections, and the beauty of its blossoms depends very much upon how the plants have been grown, weakly growths infested with red spider or thrips never throwing well-coloured or large flowers. On the other hand, if the growth is robust and clean, it is one of the most effective Orchids in existence, no other, excepting perhaps *Sophranitis*, making such a rich display of scarlet or brilliant red. In a great many places *D. grandiflora* is quite a failure, not because of any lack of attention, but simply because it is not kept cool and moist enough. While growing freely, the amount of moisture required at the root and in the atmosphere is surprising, and nothing but repeated syringings overhead will keep the foliage clean and healthy. As soon as the flowers are past the plants may with advantage be placed either out of doors or in a cool frame without any protection, unless it is from the very heaviest rains, light showers being of great benefit to the plants. This will suit them well until the foliage and stems are thoroughly hardened, when they may be repotted and replaced in the cool house. The best compost is equal parts of peat fibre, loam fibre, and Sphagnum Moss, to which add a good sprinkling of finely broken crocks. The pots or pans should be those with perforated sides, these allowing the offshoots to come to light. After repotting, a great deal of care will be needed in watering until the roots begin to run freely, but by the middle of winter the plants will usually be growing, when the supply must be increased, until in March or April and from then until flowering time the plants must be watered as described above. The winter temperature must never go below 45° and a few degrees higher must be allowed as soon as the growths appear above the compost. During the summer keep them as cool as possible and always allow a current of air about the leaves, no matter if they are blown about by the wind—in fact, the growth will be all the stronger for it, provided always the moisture is ample. They must be kept shaded, and with regard to insects prevention is much better than cure. If red spider and thrips once obtain a firm footing it is almost impossible to eradicate them, spongings, repeated at short intervals, at the same time immersing the plant, roots and all in water, being the most likely means to accomplish this. Green-fly sometimes puts in an appearance and must also be checked at once, for if allowed about the flower-spikes the blossoms will be ruined. *D. grandiflora* grows about a foot high, has erect stems clothed with narrow green leaves from top to bottom, and bears at the apex a raceme of about four or five of the beautiful richly-coloured flowers. These are about 4 inches across, the hooded upper sepal being bright rose with deep carmine veins, the side sepals being brilliant crimson in some varieties, in others more of a carmine shade. In its native habitat this Orchid grows in boggy, very moist places, yet at a good elevation where at times it is very cold. Here the stems grow to a height of 3 feet and upwards and bear spikes with upwards of a dozen flowers. It was introduced from Table Mountain, near Cape Town, in 1825. The variety *superba* is a stronger growing and very large flowering form of the type. R.

## BROUGHTON CASTLE.

THIS delightful old place, belonging to Lord Saye and Sele, but at the present tenanted by Mr. H. F. Gladwin, is situated about two miles from Banbury, in a beautifully wooded and well-watered valley. A pleasant road leads to it from the town of Banbury, which also nestles in a valley, and although there is a gradual ascent on the way, two parallel and continuous hills entirely shut out all view of the country beyond. Broughton is a little village that apparently has existed, but not extended, for many years. The visitor coming from Banbury sees first a few cottages and the school, all stone-built and stone-roofed structures, grey with age, and, passing the ancient and beautiful church, the castle is seen standing back a little way from the public road, a meadow intervening. It is a fine, imposing structure, like most houses of its time, great in architectural beauty, and in a perfect state of

specimens of Oaks, Elms and other native trees all of large size. Proceeding round the house we come to some very old walls that encompass what was apparently once a courtyard on its fourth side and the walls being loop-holed denote great antiquity. This spot is now a little lawn with two or three simple beds of Asters and Zinnias, and a border several feet wide runs round between the grass and the wall, filled, as is fitting, with hardy old-fashioned flowers, among which Pæonies, Day Lilies, Delphiniums and Phloxes were most prominent in strong clumps. The ancient walls are covered with Ivy on one side and fruit trees on the other. At the end furthest from the house there rises a little spring of water as clear as crystal. A few steps lead to it, and a rich bank of hardy Ferns at the spot is charming in association with the water. Ivy has long mantled the ancient walls of the house, but is now varied and relieved by the Virginian

of salmon-red, are borne in a dense, clammy, crowded head.

## FLOWER GARDEN.

## NOTES FROM WARLEY PLACE.

THE rock garden with its rich collection of alpine plants is the feature of Miss Willmott's lovely garden at Warley Place, and a very good description of it and the many gems that are growing there was given in *THE GARDEN* for March 3, 1894. Since that time, however, very great additions have been made, and its extent and interest enormously increased by continuing it down to the little lake, following much the same plan as that of the earlier work. A little stream runs down the centre, here and there broadening out into a pretty pool where the new

Broughton Castle, Oxford. Engraved for *THE GARDEN* from a photograph by the late Mr. J. L. Robinson, C.E., Dublin.

preservation. In appearance it represents a fine Elizabethan mansion, and there is every probability that this building has been built out of one that preceded it. There are parts of a much earlier date known to have been erected in 1407, and with the surrounding moat it most likely was a stronghold of considerable importance in the time of the Plantagenets, whilst later on we read of an important gathering in the council room of those who were opposed to the arbitrary policy of Charles I. previous to the assembling of the Long Parliament.

The illustration shows the carriage front, the moat being spanned by a little bridge, the road passing through a strong castellated gateway. The other portion of the house seen in the picture has the water within a few feet of its walls, but on the opposite side there is a pleasant breadth of green turf, and beyond the moat the ground rises, prettily undulated and diversified with groups or isolated

Creeper, also of great size. One could imagine no more peaceful spot than this to make a fine flower garden of the permanent and artistic kind, with large and simple beds of flowers set in the rich grass of this verdant valley, and the water a gay garden, too, the new hardy Lilies its chief feature. There is a good walled kitchen garden, well cropped and ably managed by Mr. Cooling (the gardener), and several glass structures are devoted to Grapes and Peaches.

**Collomia grandiflora.**—The old *Collomia coccinea*, once a popular garden annual, has given place to more showy flowers and is now rarely seen. The species now under notice has much in common with *C. coccinea*, but differs in being perennial, whilst it is also rarely seen. Mr. Perry is growing it at Winchmore Hill, his stock being from plants he found in an old Cambridgeshire garden where it was grown and supposed to be an *Epilobium*. The leaves are of a glistening green colour, and the flowers, of a distinct shade

hardy Water Lilies and other choice aquatic plants have already been planted. At its lower extremity, cunningly combined and constructed so as to form part of the rock garden, yet with a flat roof of glass overhead, and with closed ends, a house has been made and planted entirely with Filmy Ferns in variety. Many of them already show signs of doing well, and without a doubt ere long this cleverly arranged home for them will be a most beautiful spot, and its charms the greater because of its unobtrusive character, as one has not the least idea of the existence of the structure till it is entered. The new portions of this rock garden are already so well clothed, one hardly credits the fact that it was only made last winter.

There are many other nice flowers at Warley Place besides those that want a rock garden; in fact, they have grown so much in numbers that they promise to fill the ground that was formerly devoted to bush fruits and vegetables; conse-

quently, a new kitchen garden has been made. Of the best hardy flowers there are mixed borders that must have been devoted to them many years, judging by the great spreading standard specimens of such Roses as Gloire de Dijon, Rêve d'Or, Homère and other varieties. A little garden of Tea Roses occupies one nook on the lawn, each bed filled with one fine kind and carpeted with a choice tufted Pansy. Carnations are very well grown and were gay when we saw them, especially the beds of Ketton Rose, Raby, Gloire de Nancy, Mrs. Muir, and others. Herbaceous Phloxes were splendid, and there is no finer family than this to help keep the garden gay till the autumn hosts of flowers appear. Large beds are devoted to English and Spanish Irises, and a bed of Persian Ranunculus was suggestive of spring, with its profusion of bloom—the result of deferring planting till spring. Along the front of a range of vineries, and apparently in the gravel of the path itself, the Portulaca flourishes and makes a brilliant display, sowing itself and reappearing year after year. Some soil was put there in the first place and surfaced again with gravel, whilst the front wall of the vineries reflecting light and heat is congenial. In the plant houses also one may see much that is uncommon and beautiful. Scented Pelargoniums are favourite plants, and the collection of these is a large one. A little house devoted to Ferns is very charming, the back wall being entirely hidden with Maiden-hair, the front, ends and main rafters concealed by Ficus repens. The stove furnishes a home for many climbing plants of great beauty, among which we noted Ipomœa Leari, Gloriosa superba in fine bloom, the double crimson Hibiscus, bearing many large flowers, Aristolochia elegans, with many quaintly marked flowers, and Oxera pulchella. A noble specimen of Nepenthes Mastersiana with grand pitchers was seen in this house, also Rondeletia speciosa major in protuse bloom. Rochea falcata, an old garden plant of the succulent tribe, is well grown. It is a striking plant when bearing its large heads of scarlet flowers and is easily grown in a greenhouse.

**Verbascum Chaixi.**—Reference is made to this Mullein on p. 15. It is truly a handsome plant when growing vigorously. For years a plant of it has been growing amongst Rhododendrons, and it annually sends up flower-stems 8 feet high. In this particular spot the soil is heavy and retentive of moisture, hence the extreme vigour of the Verbascum.—E. M.

**Water Lilies in hard water.**—Referring to the article on page 52, I wish to know if hard water is prejudicial to these lovely flowers. I have a pool which never freezes in the hardest winter. Some years since I planted *Nymphaea alba*, but it dwindled and soon died. I afterwards planted several of Mons. Marliac's beautiful varieties: these exist, but do not produce either good leaves or any flowers. The pool is fed by an adjacent spring which contains much lime. Is this the cause of my non-success? The water does not affect *Lythrum salicaria*, several species of *Osmunda*, and *Lastrea thelypteris*, all of which thrive.—R. MILNE-REDHEAD, *Holden Clough, Clitheroe.*

**Pansies and the drought.**—We often hear from our friends, especially in the south of England, that they do not attempt flower garden decoration by growing Pansies therein, by reason of their being so liable to succumb to heat and drought. I think where the soil is deep, in good condition, and judicious mulching applied, there need be no fear of lack of flowers from Pansies from April to October. The past season, from May well into July, has been one of the driest on record, and never have I seen Pansies do better, and likely to continue doing well. Such sorts as the Countess

of Hopetoun, Golden Sovereign, and numerous blues and purples are at the end of July beautiful, and only coming to their best. The Pansies and Violas are every year becoming more popular in Scottish gardens, their easy management and free-flowering rendering them welcome in the garden of the humble cottager, as well as in the gay parterres and extensive borders of the rich. Preparation of the soil as indicated I have found meet every want in the south of England—M. TEMPLE, *Carron, N.B.*

#### SEASONABLE NOTES ON BULBOUS PLANTS.

THE most important work among bulbs at the present time is that of lifting and drying them prior to replanting them. With some species and genera the annual lifting of the bulbs is most important—indeed, essential to keep them in health. But even here again one cannot recommend any hard-and-fast rule, for the soils of gardens vary so much, and equally variable are other circumstances under which plants either thrive or merely exist. Take two extremes of soil, for instance, one of a fine dry, sandy nature, in summer hot and parched, the other a stubborn, cold, retentive clay, which in summer hardens and shrinks with the intense heat. Either of these extremes of soil is, of course, unsuitable to the successful cultivation of many bulbous plants, and must in a greater or less degree be made suitable for the plants intended to occupy it hereafter. I mention these extremes of soil merely to show how difficult it is to lay down decisive rules for guidance, and it is in this connection also that we must decide whether the majority of bulbs are benefited by annual lifting or otherwise. Naturally the bulbs would be much safer in a soil of a sandy nature even in a wet season than would be the case if the soil were heavy. But whatever the soil may be, I think we may safely take it as a guide to all our operations in bulb-lifting that the majority in a season which is both wet and cold are decidedly benefited in the long run by the absolute rest they receive through being lifted. I say benefited advisedly, because the lifting and drying, particularly where the latter is unduly prolonged, by no means tend to the vigour of the plant at the moment. As a proof of this I may mention three well-known kinds which are decidedly more vigorous when left in the soil for two or three seasons in succession. The kinds referred to are Emperor, Empress, and Grandee, three of the most vigorous of all Daffodils when established. The soil of Hampton is especially well suited to these kinds, as may be imagined when I say that the foliage of the first named will attain to a height of upwards of 2½ feet and nearly 1½ inches broad. This is usually the case with bulbs of the first size left undisturbed for two years. But these identical bulbs lifted and replanted after, say, six weeks' rest would lose at least quite 1 foot of this length of foliage in the year following the planting. This does not, however, appear to represent diminished strength all round, but affects the stature of the plant more directly, since the foliage has the same robustness, though minus the length; so that in a year like the present such kinds as appear in full vigour may be left alone, unless necessity arises for dividing the established clumps. Maximus is another fine kind that may in well-drained soils be left for even three years without disturbance; indeed, my experience of it is that it flowers with greater certainty when left alone than when lifted periodically. Supposing, for instance, the amateur may not have time at disposal for the lifting of these bulbs at

the necessary moment, it would be quite an easy matter if these were planted as clumps, by placing a handlight over them to give them a thorough season of rest. In the case of maximus, for instance, such a rest would prove highly beneficial in a cold or rainy season, while the same remark would hold good with cernuus and other of the white trumpet kinds. I have never tried it, but possibly a similar course of treatment with Emperor in the third year of planting may provide a rest at once beneficial, without diminishing the stature of the plant, as does lifting it. There are other kinds again, notably Ard-Righ, obvallaris, Mary Anderson, many of the spurious section, and cernuus and its varieties, for which annual lifting and drying seem the only way to keep them in good health. These kinds and many others, as experience and individual circumstances appear to dictate, should be lifted early each year. It will always well repay the amateur to make note each spring of any that have traces of

#### DISEASE

early noticeable in the foliage. These kinds, whatever they be, will need attention at the lifting season apart from digging them out of the soil. Upon examination it is not unlikely that these bulbs will be found infested more or less with mites, that secrete themselves beneath the outer skins and there carry out their mischievous and oftentimes destructive work. Such bulbs will need to have the old skins removed and burnt without delay. I am strongly of opinion—which is only strengthened by continued observation—that we pay far too little regard to the root pests of bulbous plants. Anything affecting the leaves and stems attracts attention because they are constantly before us, but the bulbs being in the soil for the greater part of the year, we have not the same opportunity for investigation. And then again these insects that infest bulbous plants are so minute, that they really need searching for. Once they have bored into the bulb it is quite an easy matter to carry on their work of destruction, and the more so because of the colourless nature of their bodies. I have repeatedly found these insects present on bulbs apparently healthy—so much so, in fact, that roots, leaves, and flowers have all been put forth in perfection. With badly diseased stocks, and of the more abundant kinds, it would perhaps be easier to secure a fresh lot, but with the choicer varieties they repay cleaning. When the bulbs are lifted, some discoloration may be noticeable beneath the skin, and this when the outer coats are quite sound. These discoloured skins are frequently quite wet with decaying moisture, and a source of danger if allowed to remain. In such cases no time should be lost in cleaning and removing these decaying portions, even though the bulb may be for the time disfigured. But if the base is still sound, the removal of some of the coats of the bulb will not harm them, and a return to a more healthy state may reasonably be expected. Any such bulbs, after taking away all decay, should be placed in open boxes or trays and be fully exposed to the sun. Never under any pretence place the freshly-dug bulbs in boxes with lids or covers, as it is fatal to them. Some years since a large grower of bulbs adopted this method, and to make matters worse the boxes were arranged on top of each other in a badly ventilated cellar. The result was disastrous in the extreme; many hundreds of very fine bulbs, unfortunately of the choicest kinds, sweated and were hopelessly ruined. A most remarkable circumstance in connection with this was that for several years any bulbs put into the place turned black in a few days.

It cannot, therefore, be too widely known that a full and free circulation of air must be admitted to all bulbous plants when out of the soil. More than once I have considerably resuscitated diseased bulbs of the Tenby Daffodil by cleaning and exposing to the full influence of wind, sun, and rain, and turning over occasionally, so that all sides may be reached. As in many other things, it is easier to keep such things in health by certain cultural methods than it is to recover them when once diseased. A very stubborn form of disease in the kind just named is a brown rusty excrescence, which forms over the entire basal part. It appears to be always dry, slightly warty in appearance, and, hermetically sealing the base, prevents the roots pushing forth. The result is inevitable, though with good sized bulbs it may take several years

drainage, we should hear less of the disease which is so troublesome.—E. M.

**Hemerocallis Kwanse foliis variegatis.**—In Mr. Franklyn's garden at Shedfield, where the soil is sandy, this *Hemerocallis* succeeds admirably without any protection whatever during the winter. If it were only for its foliage it would deserve a place in any garden, but, fortunately, the flowers are interesting, although not quite of the colour one cares to see over silver variegated leaves.—E. M.

**New Gladiolus hybrids.**—On page 69 you give a description of *G. Dutrieul de Rhins* from the garden of Burford Lodge, Dorking, the residence of Sir Trevor Lawrence, Bart. I saw it growing at Burford Lodge, one of a number of new French and American varieties which, under Mr. Bain's skilful treatment, have made a very vigorous growth, and will no doubt presently pre-

presented the latest outcomes of variety and quality. There were shades of maroon and deep violet-blue, and, on the other hand, pale yellow and cream, and between these two many brilliant combinations. It can scarcely be said there are any true self colours, for diversity of marking is seen on all, but some more nearly approach the self character than others, while some are very handsomely striped and flaked. Orange, salmon, cerise, violet and other striking tints are seen in unusual connection, and as the flowers are large and very freely produced, the effect is grand. Seeds were sown in spring and the plants put out in the open to bloom; they get into flower early and last for a long time. There is no other annual which makes such a striking effect when bunched as does the *Salpiglossis*, and now that a class for bunches of hardy annuals finds a place in most schedules of prizes of exhibitions held at the end of July and early in August, the *Salpiglossis* should be one of the first to be grown for the purpose. We owe a debt of gratitude to the Continental florists for the remarkable improvements made in the *Salpiglossis*, and it is not too much to say it is a flower which should find a place in every garden. Sowings may be made at the end of February and early in March for transplanting to the open, and to do a good strain full justice the ground should be in good condition.—R. D.

**Anemones in July and August.**—It may not be generally known that many of the beautiful spring-flowering Anemones, if kept out of the ground until late in the season, will grow and flower well through July and August. The other day I saw a beautiful gathering of these lovely flowers in a florist's shop in this neighbourhood, and, on expressing my surprise, was informed by the grower that the roots were not planted till the end of May, and that he had a batch of plants of the old scarlet *Anemone fulgens* coming on that would afford him a succession of bloom through August. The *Ranunculus* may be successfully treated in the same way if a succession of flower is desired. The great point to be observed is keeping the roots dry. If stored in a damp place they quickly become mouldy and spoil. There are few subjects that will stand being out of the ground in a dried state so long and yet retain their vitality.—J. C.

#### PHLOXES AT CHISWICK.

THE trial of Phloxes in the R.H.S. Gardens at Chiswick this year is an extensive one, comprising contributions from most of the leading growers. Although the hot dry season has been unfavourable to strong growth, especially to plants not thoroughly established as these, there is plenty of good strong growths carrying fine trusses. Some of the most distinct early-flowering varieties are selected and described below, but another later inspection of the collection will be made in order to make a further selection from those not yet in bloom. Magnet is a fine Phlox, with a large branching truss of carmine-red flowers. It is a dwarf grower, likewise G. W. Collock, with a compact truss of small neat flowers, which are crimson and very effective. Lafayette is a taller growing variety of branching habit, with fine flowers in large trusses, in colour a delicate blush-mauve with rosy eye. John Anderson, a deep rose self, is fine, and Mme. Hoste, a beautiful white variety which shades to blush with age. Purest of All, as the name would imply, is pure white, dwarf in habit, but robust and free in bloom. John Forbes has large flowers and trusses, and is of a soft pink shade with a deep rosy eye, whilst Albert Crousse in vermilion-red is most brilliant and striking in colour. General Chauver, somewhat similar to the preceding, is also a first-rate and beautiful Phlox. General Faidherbe has deep rose flowers of fine size and borne in profusion, and Earl of Mar in rich self crimson is well worthy of note. Miss Alice Anderson has flowers of a delicate light pink hue, deepening into rose in the centre, whilst Avalanche is another first-

*Rhododendron arboreum.* (See p. 103.)

before they are quite exhausted. The only remedy is to cut clean away any part affected as soon as seen.

The English and Spanish Irises should be lifted without delay, cleaned and properly dried, storing them for the time being in any open shed or outhouse secure from rain. In fact, a similar routine may be followed with these as with the majority of the Narcissi, so far as lifting and drying are concerned. E. J.

**Lilium candidum.**—In a strong soil I cannot get a single bloom of this Lily in a wet season, but in a dry one I have a fine display, as there are fully fifty large clumps of it growing in the herbaceous border. I am inclined to think that if we were to plant the bulbs in well prepared stations 2 feet square, completely removing all the natural soil, and filling up the space with peat and leaves, first putting in some

sent to view some very fine things. One of the new Lemoinei types is Col. Humbert, reddish rose, with a dark centre, also very fine. Anyone who has a fancy for the newer hybrids will find Mr. Bain's collection well worth a visit, and they are so well grown that they cannot fail to produce very fine spikes.—R. D.

**Lilium Kramerii.**—This lovely Lily generally shows much variation in colour in shades of pink and rose, but two distinct forms are flowering with Mr. Perry at Winchmore Hill. One has pure white flowers, while those of the other are of the deepest shade of rose, almost crimson in fact.

**Salpiglossis grandiflora.**—For brilliancy of colour, variety of tint and marking, and size and striking effect, *Salpiglossis* may be fitly designated "the Orchids of the hardy annuals." The members of the National Chrysanthemum Society who joined in the visit to Sir Trevor Lawrence's residence at Burford Lodge on the 22nd ult. saw a large bed of *Salpiglossis grandiflora*, which re-

rate white-flowered variety. *Regalis* is a rich, bright rose self, and *Matador* in vermilion-red is large and conspicuously bright. *W. Robinson* in salmon-rose is about the best of its colour, large both in the flower and truss; whilst other noteworthy varieties are *Eugène Danzanvilliers*, pale lilac with white centre, a most distinct shade of colour; *Adonis*, bright salmon-rose; and *Pont Riquet*, dark crimson-purple.

We have purposely selected varieties of clear and decided colours such as will look well and be effective in the garden. For some reason or other we rarely see this superb hardy flower well grown in private gardens, but it is deserving of better attention.

#### CHRISTMAS ROSES IN SURREY.

I FANCY that many besides myself will have been surprised to read Mr. Burbidge's statement that *Helleborus maximus* will thrive under rough and ready treatment better than any other member of the family. I have heard many express regret that whilst the common *H. niger* or *H. major* did satisfactorily, *H. maximus* never flourished with sufficient vigour to show its true character. In some gardens naturally favourable to the family, *H. maximus* will grow as freely as the typical form, but these places are few and far between. As Mr. Burbidge observes, it is the strongest growing of Christmas Roses, but in light soils that get parched in summer and in exposed positions the foliage turns yellow and the plants become so weak, that they produce blooms very little superior to those of the common *H. niger*. This is the condition in which I have most frequently seen *maximus* in Surrey gardens, where the soil in a general way is of a light description and easily parts with moisture. Several years ago I made a plantation of Christmas Roses consisting of *maximus*, *major*, *angustifolius*, *Riverstoni*, *ruber* and *caucasicus*. I am in the unfortunate position of having no naturally shaded situation, and the plants were set out in the full sun. I thought that by giving good attention to watering I should induce them to flourish, but I was mistaken. In spite of all I could do they would not grow with sufficient freedom to allow of producing flowers in quantity. Each spring they started freely into growth, but in July or early in August, just when the crowns should be plumping up, the greater portion of the leaves took on a yellow tinge, and in the course of the winter the plants were to a more or less extent defoliated. Of the varieties above mentioned *maximus* suffered most, and, judging from my own experience and from what I have seen elsewhere, I have come to the conclusion that if one wishes to see this grand Christmas Rose in true form, it must, in the great majority of gardens at least, get good culture. It is one of those hardy flowers that under suitable conditions grows with remarkable vigour, but unless these can be accorded it, it is hardly worth planting. On light soil and in the southern counties a certain amount of shade is, I am convinced, indispensable, and good drainage is absolutely necessary. The roots of *maximus* are even more fleshy than those of other varieties, and consequently suffer more from stagnant moisture in the winter-time. Of all the Christmas Roses I am acquainted with *caucasicus* is the one I should recommend for growing in a rough and ready manner. This is the only one that has given fair results with me when placed in full exposure. Mr. Burbidge does not mention it, and I have remarked that it has very rarely been mentioned by those who have written about Christmas Roses in *THE GARDEN*. I am surprised at this apparent want of appreciation of a Christmas Rose that is possessed of ex-

ceptional powers of endurance. The foliage is very rich in colour, the growth is vigorous, the flowers are thrown up well, and are produced in profusion. Under very trying circumstances *H. caucasicus* will retain its foliage, remaining in good condition when *maximus* and *major* have lost all their leaves. In pots this Christmas Rose does remarkably well. I have had plants of it that remained in the same pots for years and bloomed with freedom annually. Mr. Burbidge refers to *ruber* or *Apple Blossom* as being a variety of *maximus*. In habit of growth they resemble each other to some extent, and the pink tint that distinguishes *maximus* is even more pronounced in *Apple Blossom*, but the time of blooming is quite different. *Maximus* will often open its first blooms in October, whilst *Apple Blossom* rarely expands them till January. I believe I am correct in saying that *maximus* never yields seed in this country, so that I fail to see how it can have given birth to a variety that is, moreover, as regards time of blooming, quite distinct from it. I imagine that the variety *Apple Blossom* turned up in a lot of imported plants, probably from the Italian Alps. It may, however, be a hybrid, for although *maximus* does not seed, its pollen may be potent when placed on other kinds. I have some seedlings which by their leafage seem to show that *maximus* may have been one of the parents. Several years ago I made crosses with all the varieties above mentioned and raised some 1500 seedlings. These showed considerable diversity of form and colour in the leaves, but, unfortunately, the heat and drought of 1893 were too much for them, and I lost the greater portion just as they were coming into blooming condition. In making these crosses I used the pollen of *maximus*, but, very few of the seedlings having bloomed, I cannot say if it had any potency. There is one cross that gives an excellent Christmas Rose, *i.e.*, *angustifolius* with *caucasicus*, the latter being the seed-bearer. The habit of this hybrid form is remarkably vigorous, the leaves being rich in colour and of great substance, which enables them to resist parching heat. The blooms are thrown up on long stalks and vary a little in form. *Riverstoni* is a fine Christmas Rose, and I believe it to be a garden hybrid. I have plants which as regards leafage, habit of growth and flower appear to me to be identical with it, and they came from crossing *caucasicus* with *major*. The common *niger* varies considerably in form of leaf, colour, and profusion of bloom, as one may easily see when raising it in quantity from imported seeds. A good form of it is, I consider, as useful as *major*, which is preferred by those who grow for profit, and is certainly better adapted for ordinary garden culture than that variety, owing to the tougher nature of the leaves. J. C. B.

**Begonia Emperor.**—Great strides have taken place among tuberous-rooted *Begonias* within the last twenty years. Many of the varieties then popular are now quite forgotten, but one of them—*Emperor*—is employed for bedding in Hyde Park; and though there are many beds of the larger and rounder-flowered class, yet this old variety was by far the best of any when seen on July 28—a day of continuous rain. The older forms, and *Emperor* among them, are taller in growth than the newer kinds, whose flowers, being larger and heavier, were weighed down with the wet, and were consequently but little seen, while the narrower-petalled flowers of *Emperor* were in no way affected. The flowers of this are of a bright vermilion. *Emperor* was raised by Messrs. Veitch and received a first-class certificate in 1875, but was not put into commerce till two years

later. It was raised at a time when the parentage of the different varieties was given, that of *Emperor* being announced as *Clarkei* × *Chelsoni*. The former of these—*Clarkei*—was imported by Messrs. E. G. Henderson and Son from Peru, and flowered with Colonel Clarke at Welton Place, Daventry, in 1867; while the other, *Chelsoni*, was obtained by crossing *B. boliviensis* with the hybrid form *Sedeni*, remarkable from the fact that it was the first hybrid tuberous *Begonia* raised in this country, its parents being *B. boliviensis* crossed with an unnamed species.—H. P.

**The seed harvest.**—Now is a good time to look after the ripe or ripening seeds of all good hardy flowers. By gathering the best seeds of such plants as Poppies, Honesty, white Foxgloves, Scillas, *Chionodoxas*, *Narcissi* or Primroses, and sowing them at once in half-wild places now that the earth is warm and moist after the rain, the bounty and the beauty of the garden may be made to overflow into the woods and walksides, the fringes of carriage-drives, or even into the hedges near one's home. The sowing of seeds and the rooting of cuttings or layers almost continually are among the most important of all operations in good gardens. To the private landscape gardener especially is this necessary, since he or she must always have at command a good stock of healthy young stock for the finest groups and masses. I was in an old country garden the other day where the masses of Foxgloves, blue Delphiniums, *Alstromerias* and crimson Poppies were splendid, as seen blooming in bold groups where sown. Common Honesty and *Hesperis matronalis* I saw lovely this last spring fringing a mile or so of a grassy wood path, along which the seeds had been scattered two years ago, and white Foxgloves and Welsh Poppies sown last season promise to rival the crucifers next year.—F. W. B.

#### FLOWER GARDEN NOTES.

**CARNATIONS.**—Information as to the way in which individual varieties of Carnations came through the winter of 1894-5 would be very interesting, in the open ground I mean, not wintered in frames. There is no doubt in the majority of places Carnations in the open ground were hard hit last winter, but I cannot rightly understand why it should be so unless some varieties are much more tender than others, and the really hardy sorts could be counted on, say, ten fingers. The situation would not seem to have much to do with it, or why are failures reported alike from high and dry and from damp, low-lying districts? Indifferent plants are often answerable for failures, it being simply impossible to expect plants to come safely through a severe winter if when required for planting out they are only just beginning to root. A hardy constitution should be one of the first considerations in choosing varieties of border Carnations, coupled with free-flowering properties and non-splitting. As a considerably increased number of Carnations is to be grown, I have already started layering, the object being to secure a batch of nearly 2000 plants for a new bed. The bed will be cut out on turf on a poor lawn, and in order to give the plants a start I shall bastard-trench it, working in a liberal dose of well-decomposed manure on the top of the first spit. We are starting our layering with *Countess of Paris* and *Ketton Rose*, two varieties that root somewhat slowly, and consequently are longer growing into good plants. The grass on all members of the *Clove* section is very strong and succulent—a fact that is rather surprising when one considers the length of time the beds lacked even a little moisture, and at once stamps the *Carnation* as a capital dry-weather plant. In a season like the present there is no doubt one is greatly indebted to a careful preparation of the beds prior to autumn planting, and also a good surface mulching put on, if not in winter at least early enough in spring before the sun gets sufficient power to dry out the ground.

**TUFTED PANSIES.**—It has been a capital time for the propagation of tufted Pansies. The rain

came the day after the first batch was inserted, and they have been kept damp ever since by occasional showers. I fancy we shall have a good strike, despite the fact that the cuttings were none of the best; in fact, the majority are on the safe side, as is evinced by the fact that the very small flower-buds that were not removed when the cuttings were taken are now opening. It was not possible to get sufficient cuttings of several varieties, and in order to secure the amount required we shall either have to split up the old stock in the autumn or take later cuttings; probably the former, as late insertion is not satisfactory. No plants have benefited more from the rain than these Pansies; they were beginning to look very shabby in our light dry soil, but the soaking received, accompanied by a thorough clearing away of all dead flowers, has quite transformed the beds. A recent note in THE GARDEN, calling attention to the splendid summer display afforded by tufted Pansies associated with Fuchsias, was very appropriate. No better beds are to be found anywhere than those filled in this manner, the three necessities being well-grown plants of free-flowering varieties of Fuchsia, thin planting of the same to show them off to the best advantage, and a happy arrangement of colours. All the purple, dark mauve and purple and white or purple and mauve Violas, as represented by Purple King, J. B. Riding, Edina and Iona, also the rose-coloured William Niel, look remarkably well with Mme. Cornclissen Fuchsia, an old variety, but still one of the best for this purpose; whilst darker Fuchsias would naturally be carpeted with white or light-shaded Violas, White Swan and Lillias being two of the best.

**NEW HERBACEOUS PLANTS.**—Perhaps rare would be a better word than new, as one or two things mentioned below have been out several years. I have, however, ventured to call attention to them owing to the fact that as yet they seem to be comparatively unknown even in many places where herbaceous plants are largely grown. Let me again recommend *Achillea ptarmica* The Pearl as a first-class thing alike for the border and for furnishing an abundance of lasting white flowers. The extra vigour of the plant as contrasted with the ordinary double form of *ptarmica* is quite in proportion to the extra size of the flowers, and the growth must either be pegged or it must be planted well in the centre or a little towards the back of the border. It increases readily by division of the crowns in autumn. *Platycodon* or *Campanula Mariesi* is a very fine front row plant, producing flowers of a very pleasing shade of blue, often nearly 3 inches in diameter; this is one of the best of the dwarf Bellflowers. *Tiarella cordifolia* is another charming plant of comparatively dwarf habit that, planted in blocks along the front of borders, has a very striking appearance; seen in the distance it looks almost like a miniature *Bocconia cordata*. This again, although an old plant, is by no means so well known as its merits deserve; it is fine for the back of large borders or to face shrubberies, and comes in very acceptable in a cut state for all vases. In scarlet shades the double form of *Lychnis chalcedonica* is a long way before the single variety, lasting so much better either in the border or in a cut state. A plant I have tried this year for the first time, and which I can heartily recommend to all who have not already grown it, is *Hemerocallis Thunbergi*. Some of the Day Lilies have dull-looking flowers, but those of *Thunbergi* are of a beautiful clear yellow with a delicate perfume. Those who like novelties, either in the border or for vases, cannot do better than try *Eryngium amethystinum*, about the best of its class; the peculiar shade in the flower-heads is very lovely. Another strange shade of colour, to my thinking more odd than beautiful, is furnished by *Echinacea* (better known perhaps as *Rudbeckia*) *purpurea*. It supplies a colour seldom met with in hardy flowers, and as such is valuable where variety in colour is required. It is hardly necessary to include in the short list of things tried for the first time the names of any new varieties of those herbaceous plants that are now represented so

strongly, and indeed in many cases such fine things are obtainable from a packet of seed, that the purchase of named sorts is not advisable. *Pentstemons* and *Antirrhinums*, for instance, are procurable in endless variety and very fine in quality from an ordinary seed packet.

Claremont.

E. BURRELL.

#### NOTES ON HARDY PLANTS.

***Dianthus Seguieri*.**—This as it grows here presents the appearance of a pigmy *D. neglectus*. The flowers are rosy crimson, the size of a sixpence and only just overtop the dense grassy cushions of foliage scarcely 2 inches in stature. I believe several forms than the correct one have gone under this name in commerce, and I feel sure the true thing is nothing like common.

***Dianthus cinnabarinus*.**—This uncommon Pink is so named from its true cinnabar-red flowers. It is at once distinct and rare. You by no means find the plant in ordinary collections or trade sources, not even when the name is seen in the lists. I have had amusing and annoying experience in trying to again obtain this gem during the past two years. I had divided my best plant with a friend, and when weeding, one of my garden boys pulled out the last morsel, and it has only been by going back to my friend for a plant that I have been able to get possession of the true plant. I mention this to show its rarity and in the hope that those who have it will try to propagate and distribute it.

***Geranium balkanum*.**—I believe this is a name that should be discontinued, but somehow improper names are not easily got rid of, however strong and reasonable the arguments may be. I believe on some fresh material being collected about four or five years ago a well-known botanist applied this name, and, as afterwards appeared, he had failed to identify it as the old *macrorrhizum*, which many of us had almost forgotten. However, the plant in suitable places, being a strong grower, is well worth a place. The flowers are almost brick-red, the leaves handsome and fragrant, especially when touched. For this quality alone the plant should be placed in the woodlands and semi-wild gardens.

***Dianthus Atkinsoni*.**—The rich and unique crimson of this single Pink constitutes one of the brightest bits in the garden. It is hard to say why so many fail with it; it certainly gives no trouble here, which is more than I can say for many of the alpine species of the *glacialis* and *alpinus* group. Its duration is perennial beyond all doubt, but the way in which it flowers—so long and so profusely and leaves itself perfectly nude of grass—may suggest it is worn out, and these features I have sometimes thought might account for the impression that the plant is but biennial or a poor perennial. The grass grows rapidly in the autumn.

***Boykinia occidentalis*.**—This is a somewhat stronger plant and bigger in all its parts than *B. aconitifolia*, and especially are the panicles of blossom spreading and elegant. Its chief beauty, however, is the pretty small flowers and the manner in which they change from pure white to a coral rose hue. A big panicle of many tints is most beautiful, and as cut material must vie with, or perhaps to many people's minds excel, the paniced *Gypsophila* for effect, though by no means are the sprays so large. I have only as yet tried this American plant in one way—north aspect and moist. How it would behave in a drier position I cannot say. My plants came from California and withstood the frost of last winter.

***Androsaces*.**—I fear it is far more than we can hope for, to manage or keep all the species in lowland gardens and in districts near big smoky towns. I mean by all, those eighteen or twenty kinds we sometimes meet with in trade lists. It is by no means difficult to establish them all and even get them for a season into a state of vigorous growth, but it is a very different matter to keep them going for even two or three years. Either

their native vigour gets used up, their glands become clogged, fogs deposit the atmospheric impurities about their roots, and after one or two winters they die. I have managed for many years to keep seven or eight kinds in my garden here, a locality four miles from one of the blackest cities in England. I will give their names: *Carnea*, including its variety *Laggeri*, *sarmentosa*, *villosa*, both European and Himalayan forms; *foliosa*, *Vitaliana*, *Chamaejasme*, *lactea*, and *helvetica*. Three of these, viz., *sarmentosa*, *villosa*, and *Chamaejasme* (and they are very hairy or glandular) are no doubt helped by their stoloniferous mode of self-propagation to so re-invigorate themselves annually. I venture with a good measure of reason to commend at least these kinds that have succeeded here as worthy of trial.

***Gentiana ornata*.**—In this Yorkshire climate for the first time I have tested this for hardiness in the open, and it has not only come through safely, but at its usual date (the date of pot plants in cold frames as in the past four years) it is flowering. The position is at the bottom of a rockwork, aspect S.S.W., the stone work being 4 feet to 5 feet high. True this may be termed a very sheltered place, but as the style of rock gardening goes it is a common one, and implies no further protection of plants than the structural condition. Anyhow the winter of 1894-5 would be a severe test.

***Adenophoras*.**—These are not much grown, and for showiness can scarcely be said to equal the *Campanulas* they are so nearly related to. Still, they are not without their pleasing features—at least, the two better known kinds, *liliifolia* and *suaveolens*. These are of a delicate pale blue, you may say mauve or heliotrope, sweet and lasting. They will grow almost anywhere, and for wild gardening would be suitable in every way.

Woodville, Kirkstall.

J. WOOD.

#### LILIUM CHALCEDONICUM.

By the middle of July the greater number of the different Lilies are over, and as several of those that have not yet bloomed are still in the bud state, the number of those just now in full flower is very limited. One of the brightest is *L. chalcedonicum*, known also as the scarlet Turk's-cap Lily, which reaches a height of 3 feet to 4 feet, the stem being very thickly clothed with pale green leaves, while the somewhat small, but symmetrically shaped blossoms are borne in a loose cluster on the upper part of the stem. The segments of the flower are thick in texture and their colour is a bright sealing-wax red, though in this respect individuals differ. I have seen some remarkably fine examples of this Lily in old-fashioned cottage gardens. It is now-a-days not very plentiful, and there is always during the dormant season a fair demand for it and exceptionally fine bulbs are difficult to obtain. This is not one of the peat-loving Lilies, for it will succeed in a stiffer loam than many other species; in fact it does best as a rule in what may be spoken of as good garden soil of not too sandy a nature. It is occasionally liable to be attacked by that mysterious Lily disease which plays such havoc with the white *Madonna* Lily in many places, but it does not suffer to anything like the extent of this last. The bulb of *L. chalcedonicum* is rather loose in texture and should be handled very carefully, otherwise some of the outside scales are liable to become detached. A great deal has been written concerning the evil effects of late planting in the case of Lilies in general; still it is well known that some are less affected by it than others. *L. chalcedonicum* is among those which are greatly benefited by early planting, for the new roots which are pushed out from the base of the bulbs soon after the stems die down are few in number, but very stout, so that if only one or two are broken the vigour of the bulb is influenced thereby. The leaves of this Lily are usually among the first to show above ground in the spring, for as a rule they follow close on those of the Nankeen Lily (*L. testaceum*), and about the same time as those of *Lilium Hansonii*. *L. chalcedonicum*, like

some other members of the Martagon or Turk's-cap group, will sometimes show but little growth above ground the first season after being transplanted, but as a rule the next year it will have recovered from the check. It is also especially interesting as being one of the parents of the Nankeen Lily (*L. testaceum*), which is a great favourite with many. This last resulted from the intercrossing of *L. candidum* and *L. chalcedonicum*, while on page 11 of the present volume of THE GARDEN a new form of the same section is noticed as flowering with Mr. Ware at Tottenham. This is *Lilium Beerensii*, the result of a cross between *L. chalcedonicum* and *L. excelsum*, which is synonymous with *L. testaceum*. The flower, which is more in the way of *L. excelsum*, is of a deep apricot colour, with long prominent orange-searlet anthers. Of Lilies flowering in the open ground in the middle of July we have *L. elegans venustum*, remarkable as being the last of the elegans group to bloom; *L. longiflorum*, in several forms; *L. auratum*, or at all events some individuals of this species, for others may not bloom till summer is well advanced; *L. Batemanni*, of a reddish apricot tint, and *L. Leichtlini*, pale yellow dotted with red. The future display of Lily blossoms is principally furnished by *L. tigrinum* in several varieties, and *L. speciosum*, of which numerous forms are in cultivation. H. P.

**The white Antirrhinum.**—Where a good form of the white Snapdragon is possessed, it should be kept up by cuttings. Some years since I obtained from Mr. Molyneux some cuttings of a fine strain, the whitest I have seen, with only the faintest suspicion of yellow at the lip. This naturally enough comes absolutely true from cuttings, but I have never raised any seedlings that inherited the purity of tint of their parents. The lasting qualities of this white Antirrhinum are simply marvellous; the cuttings are stopped twice during the early spring, and when put out in the beginning of May are bushy little plants; by the commencement of June they are in flower and continue blossoming with short periods of intermission until November. To keep up this continuous display of bloom great care must be taken not to allow the plants to become weakened by producing seed-pods. Large patches are much more effective than single plants dotted about, and contrast well with breadths of *Lychnis chalcedonica*, *Salvia patens* and *Glaucidium brenchleyensis*. Two-year-old plants, on the other hand, are more decorative when grown in isolated positions, as they often attain a height of 3 feet and measure almost as much in diameter, and when in full bloom are strikingly effective. I regret to say that all my stock of old plants was destroyed by the late winter and the garden has been deprived of an additional feature of beauty through their absence. — S. W. F., *Torquay*.

**The hardiness of the sweet-scented Verbena.**—A good many of us have long ago proved this general favourite practically hardy throughout the eastern counties. It is even hardier than Tea Roses against south and west walls, and throughout Devonshire, Cornwall, &c., it is as hardy as Hydrangeas. Protected with ashes, as described by "E. J.," it may be treated as hardy in most gardens. It is only when thus treated, as a rule, that this plant can be thoroughly enjoyed. The older and stronger the plants, too, the hardier they seem to become. To make doubly sure of their hardiness the tops should be left intact until the plants begin to break in the spring. Only those who have grown these fragrant plants at home in the open can realise the amount of protection their tops can afford under free culture and treatment.—D. T. F.

**Lilium odorum.**—This is the Lily to which a first-class certificate was awarded by the floral committee of the Royal Horticultural Society on July 23 under the name of *L. japonicum Colchesteri*. A coloured plate of it was given in THE GARDEN, April 17, 1886, as *L. japonicum*, which elicited a communication from Mr. Baker at Kew to the effect that it represented the true *L.*

*odorum*. Whether known, however, as *L. odorum*, *L. japonicum*, or *L. Colchesteri*, there is a good deal of confusion existing between this Lily and *Lilium Browni*, though the two are totally distinct, that is to say if the *L. Browni* of the Dutch cultivators is taken as the type, for some imported forms, such as I have seen at Kew, appear to be of a somewhat intermediate character. There are several very marked points of difference between *L. Browni* and *L. odorum* other than those set forth in THE GARDEN, p. 72. In the first place, the bulbs are totally distinct, that of *L. odorum* being broad at the base with a slightly raised centre, while that of *L. Browni* is narrow at the base and widens out considerably, the upper part peculiarly flattened. The colour of the bulbs, too, is quite different, for *L. odorum* is yellowish, after the manner of *L. longiflorum*, while *L. Browni* is of a reddish tint. Directly they appear above ground the two can be readily distinguished, for the young shoots of *L. odorum* are nearly green, while those of *L. Browni* are reddish brown, which tinge prevails to a great extent in all stages of growth. The difference between the foliage and mature flowers of the two is well set forth on p. 72, except the colour of the leaves, which in *L. Browni* are of a deep shining green, while those of *L. odorum* are of a paler unpolished tint. Except a few European species, *L. odorum* is the oldest of all Lilies, yet it is now quite a scarce kind. It was introduced in 1804. In the "Dictionary of Gardening" *L. japonicum* is given as the correct name, with that of *odorum* as a synonym.—H. P.

#### LILIUM SPECIOSUM.

THOUGH it will be a long time before the flowers of this Lily expand in the open ground, yet beautiful flowering examples may be seen in Covent Garden Market, having been brought on under glass. They are extremely useful and more appreciated than they would be later on when those outside will be in bloom. Some growers cultivate vast numbers of this Lily, the general plan being to pot the bulbs as soon as possible, and by keeping them cool encourage root action before the tops start into growth. As the stems develop liquid manure is of great service, and a sharp look out must be kept for aphides, which, as in the case of *Lilium Harrisii*, soon cause considerable damage. Regular fumigation is the best way to keep them in check. The varieties of *L. speciosum* are numerous, for we get several from the Dutch cultivators and others from Japan. From Holland we get roseum and rubrum, but, as generally sent, the difference is only in name. Though surpassed in colour by some of the Japanese forms, the bulbs from Holland are of a very beautiful variety, and can as a rule be had in flower rather earlier than those from Japan. The white variety sent from Holland is that known as album, which differs widely from the Japanese *Kratzeri*. In album the bulbs are of a dark mahogany colour, deeper in tint, indeed, than in any other variety of *L. speciosum*. The stems and leaf-stalks, too, are dark, while the flowers are heavily suffused with chocolate on the exterior, but white within, though after they have been expanded for a few days the white often acquires a pinkish tinge. *L. Kratzeri*, on the other hand, has yellowish bulbs, while the flowers, whose segments reflex in a very graceful manner, are white, tinged, especially when partly expanded, with green on the exterior, while the inside of the blossoms has a greenish stripe, which extends partly down the centre of each petal. The very deeply coloured forms which are sent to this country from Japan in considerable numbers, sometimes under the name of rubrum and at others that of Melpomene, are very beautiful, but for the earliest blooming plants the forms from Holland find favour with most cultivators. For general decoration *L. speciosum* has a great advantage over most other Lilies. In the first place it is of good constitution, and retains its foliage well when grown in pots, which several Lilies do not; next it flowers at a time when many green-

house plants have lost their freshness, and consequently affords an agreeable change, while the perfume of the blossoms is not nearly so overpowering as that of *L. auratum* and its numerous varieties. H. P.

## GARDEN FLORA.

### PLATE 1026.

#### HIMALAYAN RHODODENDRONS.

(WITH A COLOURED PLATE OF *R. GRANDE*.)

THE headquarters of the genus *Rhododendron* is undoubtedly that portion of our Indian Empire overshadowed by the Himalayan Mountains. No area of similar extent has furnished so large a number of species that may be grown in the British Isles, neither have any been found which can rival the Indian species in their tree-like size or in the beauty and variety of their flowers. Judging by what we already know of the flora of the less accessible parts of China, it is probable that the genus may, so far as mere numbers go, be more strongly represented there than in India, but it is scarcely possible that any will possess the regal characteristics of the finer species inhabiting the middle elevations of the Himalayas. The one name which more than any other will ever be associated with these plants is that of Sir Joseph Hooker. Previous to his travels in the Himalayas but few were known, and it was directly due to his efforts that the great majority of the species were introduced. Some of the finest specimens in Cornwall and Wales are those raised from the seeds he sent to Kew forty-five years ago. In his fine work on "Sikkim Rhododendrons," published soon after his return, a little over forty species are enumerated, and it is a curious fact that this number has scarcely, if at all, been added to since that period. The altitudes at which they grow range between 4000 feet and 14,000 feet, but it is at heights of 10,000 feet and upwards that the genus is most abundantly represented. Above 12,000 feet Sir J. Hooker says that three-fourths of the whole vegetation consists of *Rhododendrons*. The climatic conditions that prevail there have not, of course, their exact counterpart in any part of Britain. The mean temperature at Darjeeling (in which neighbourhood most of the species are found) does not widely differ from that of London, but the extremes of heat and cold are much greater here than there, and it is only a few that can be said to thrive out of doors really well and flower in the London district, although a considerable proportion can be kept perfectly healthy in foliage when grown in well-sheltered positions. The greatest successes with Himalayan *Rhododendrons* in the British Isles have been obtained near the sea in the south and south-western counties, where the temperature is equable and the atmospheric moisture abundant. The districts in which they are grown to greatest perfection are near Swansea, in Wales, and about Falmouth, in Cornwall. It ought to be the task—an extremely pleasant one—of all those who desire to grow them either outside or under glass to visit one or both of these places.

The general conditions which attend the successful cultivation of Himalayan *Rhododendrons* do not differ materially from what the great bulk of the Ericaceae family requires. A soil which is naturally peaty is no doubt the best, but it is by no means essential; they may be grown out-of-doors in loam either light or mode-

\* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severeyns.

Elyonurus acicularis (L.) DC.

rately stiff so long as lime is absent. A plentiful admixture of leaf-soil is always beneficial. Although these plants (so far as I have been able to judge) flower better after a hot summer, especially when grown under glass, it by no means follows that they like full exposure to the sun. On the contrary, the best position for them in a house is at the north end, and in the open air they should always, if possible, be planted near trees—not absolutely under them, but near enough to be screened from the sun for a few hours a day. The advantage of such a position is also felt in winter in the protection afforded from cutting winds and frost. This summer I have especially noticed that young plants of *R. fulgens* and *R. campanulatum* are badly scorched where the midday sun has pitched directly on them. Either indoors or out a uniformly moist condition must be maintained at the root. When planted out in

from January till May, and no greenhouse plants provide a richer display. The low temperature they require makes their cultivation quite inexpensive after the initial outlay. It would be well worth while devoting a house entirely to them, for even out of flower their fine foliage makes them attractive.

The following is a list of species grouped according to their hardiness:—

*Hardy near London.*

Anthopogon	Fulgens
Campanulatum	Glaucum
Campylocarpum	Niveum
Ciliatum	Thomsoni
Cinnabarinum	

*Hardy in Cornwall and S. Wales, also in especially mild localities in the midland counties or even in parts of Scotland.*

Arboreum and vars.	Keysi
Barbatum	Lanatum

This species attains a height of 30 feet, and is found on the Sinchul and Tonglo Mountains. It is grown out of doors by Sir J. T. Llewelyn at Penllergare.

*R. FALCONERI.*—This is allied to *R. grande*, but has a compact truss and differs much in foliage. Sir Joseph Hooker says that on the Tonglo Mountain, where *R. grande* is found, that species grows up to altitudes of 10,000 feet, and is then suddenly replaced by *R. Falconeri*. As might be expected from this, it is much hardier than *R. grande*. I saw it thriving very well in the famous Duchess' garden at Belvoir some years ago, but Mr. Divers has lately stated that it has been severely damaged by the past winter. It has large oblong leaves about 10 inches long, coated beneath with reddish down, dark green, slightly downy and curiously wrinkled above. The flowers are of a curious shade of creamy white tinged with lilac towards the base. *R. eximium* is a fine variety of this, differing in its bright pink flowers and the thicker reddish brown fluff on the upper surface of the leaves.

*R. ARBOREUM.*—This, the longest introduced and perhaps the best known of the Himalayan species, is also one of the largest in stature and bulk and one of the most variable. The various forms may roughly be divided into two groups, the one with foliage that is silvery beneath, the other having the underside of the leaf covered more or less with a reddish tomentum. The leaves of all are from 5 inches to 8 inches long, lanceolate and acutely pointed, the trusses rounded or sometimes almost conical, with the flowers closely packed. The colour of the bell-shaped corolla varies from rich crimson to almost white. The typical form of *R. arboreum* has bright red flowers and leaves that are silvery beneath. The plants known under the following names belong to the arboreum group, some having been given specific rank: *Campbellie*, flowers rosy purple, leaves rusty beneath; *limbatum*, flowers rosy purple, leaves silvery beneath; *nilagiricum*, flowers rosy, leaves reddish beneath; *cinnamomeum*, flowers almost white; *Windsori*, flowers and trusses smaller, rich crimson. The species was used many years ago for hybridising with the American and Caucasian species—*Nobleanum* and *altaclerense* being the first results. Its blood, no doubt very attenuated sometimes, runs in some of the fine red-flowered garden varieties now grown. It was introduced about 1820.

*R. BARBATUM* is described as being in a wild state 40 feet to 60 feet high; I have seen it about 12 feet high in Cornwall. The name refers to the bristly hairs which clothe the short petiole, and are the most distinguishing character of this species. The leaves are 5 inches to 7 inches long and of broadly lanceolate shape. The flowers, of a rich blood-red colour, are borne in a compact truss 4 inches or more in diameter.

*R. LANCIFOLIUM* is probably a small-sized variety of *barbatum*. It has narrow lanceolate leaves, and the petioles, instead of being bristly, are covered with curious warts. The flower-trusses also are smaller.

*R. HODGSONI.*—A spreading shrub or small tree, rarely more than 12 feet high, branching from the base and growing outwards rather more than in height. The leaves are very stout in texture, upwards of 1 foot long, covered beneath with a grey (or very rarely reddish) tomentum, the upper side being of a bright, somewhat metallic shade of green. The flowers are of a pale rose-purple. On the whole it is more noteworthy for its foliage than its flowers. It is grown outside in both the Welsh and Cornish gardens, and may possibly be hardy enough for the London district.

*R. WIGHTI.*—A small tree, found at elevations of 11,000 feet to 14,000 feet. It appears to be allied to *R. Hodgsoni*, and does indeed occur on the same mountains as that species, but at higher altitudes. It differs, however, in having yellow flowers; these are individually  $2\frac{1}{2}$  inches across, and are produced in large rounded trusses. The leaves are very firm and stout, measuring 6 inches to 10 inches in length by about one-third as much

*Rhododendron Falconeri.*

beds under glass there is, however, often more danger of overwatering than the reverse, especially in newly-made beds. The mistake is sometimes made of giving too great a depth of soil; 2 feet, I should say, is ample. A soil consisting mostly of peat is best for plants indoors; leaf-soil may be added, but if loam is introduced it should be of a rather light, sandy nature. All the larger species may be very well grown in tubs, for this admits of the plants being taken outside during summer—a course which is always conducive to good health and abundance of bloom. Fire heat is not needed at any time of the year; in fact, an unheated house, constructed so that the roof may in great part be left open in summer, is the best for these *Rhododendrons*. In Cornwall and Wales they enjoy great popularity, but in the more inclement parts of the kingdom, where cultivation under glass is necessary, they do not obtain the attention they deserve. They flower mostly

Falconeri	Lancifolium
Grande	Triflorum
Hodgsoni	Wighti

*Cool Greenhouse.*

Aucklandi	Hookeri
Camelliaeflorum	Maddeni
Dalhousiae	Nuttallii
Edgeworthii	Pendulum
Formosum	

*R. GRANDE* (syn., *argenteum*).—The subject of the plate is undoubtedly one of the finest of all *Rhododendrons*. Unfortunately, it is not hardy near London. The flowers occur in large rounded trusses, each flower being  $2\frac{1}{2}$  inches across, white, beautifully flushed with rose on first opening, and marked with a ring of purple blotches at the base. The leaves, whilst of a rich dark green above, are silvery white beneath. The accompanying plate gives an admirable presentation of the flower and truss, but want of space prevents the beauty of the foliage being shown. I have measured leaves considerably over 1 foot long.

in width; when young they are quite white underneath, becoming grey with age.

**R. NIVEUM.**—One of the hardest species, but far from the most showy. The young leaves are covered with a white tomentum all over; the upper surface afterwards becomes deep green and glabrous. The flowers are closely packed in a small head, and are of a purplish lilac colour.

**R. FULGENS.**—This is at once one of the richest coloured, hardest and rarest of Himalayan Rhododendrons. It blooms out of doors very early in the year (March), and does not always escape the damaging spring frosts, but if it does, it is without doubt the richest and most brilliantly coloured hardy shrub flowering at that time of year. The flowers are in compact rounded trusses about 4 inches across, their colour a rich, but bright blood-red. The leaves are coated beneath with a rusty coloured felt, the plant being often represented in gardens by the less striking *R. campanulatum*, which can scarcely be distinguished from it when in leaf, but which has white or pale purple flowers. The true plant has been grown outside for many years in the Rhododendron dell at Kew, and it has never been injured by frost, nor does it ever fail to set abundance of bloom. In the Himalayas it grows at elevations of 12,000 feet to 14,000 feet.

**R. CAMPANULATUM.**—This is perhaps the hardest of all the Himalayan species, but it is far from being the most attractive. It is valuable, however, in flowering during spring (April) when few other Rhododendrons are in bloom in the open. It forms a widely spreading bush, rarely more than 6 feet high. The leaves are coated beneath with a brightly coloured reddish felt. The flowers are pale purple, changing to nearly white, or in some forms almost white from the first. Introduced in 1825. It reaches up to altitudes of about 15,000 feet.

**R. LANATUM.**—This species, as the name implies, is distinguished by its wooliness. The young branches, both surfaces of the leaves and the petioles are covered with a dull white or tawny tomentum, more so than any other Himalayan species. The flowers are 2 inches across, sulphur-yellow, and six to ten are borne in one head.

**R. AUCLANDI.**—In many respects this is the finest of species requiring greenhouse treatment. It has smooth foliage of a rich and glossy green, each leaf being from 6 inches to 12 inches long and of narrow oblong shape. Its large, saucer-shaped flowers are of the purest white and frequently 6 inches in diameter, from five to seven of them being borne on a truss. This species attains the dimensions of a small tree, its stems being of a grey colour with the bark peeling off. It has been used for hybridising purposes, but not so much as might have been. A hybrid between it and *Hookeri* called *kenwense* (raised at Kew in 1874) has flowers of a pale flesh colour, not so large as those of *Aucklandi*, but more numerous in the truss. There is also a very pretty hybrid known as *Aucklandi hybridum* which is hardy in the London district; its flowers are pure white. This species is named in honour of the one-time Governor-general of India—Lord Auckland. It is also known as *R. Griffithianum*.

**R. THOMSONI.**—Almost similar in colour to *R. fulgens*, the flowers of this species are borne in loose trusses more after the fashion of *Aucklandi*. It is quite hardy in the London district and flowers in the early part of April; the leaves are elliptical, 3 inches to 4 inches long, very dark green above, but semi-glaucous beneath. This is a plant of bushy habit; the largest I have seen is growing at Tremough, near Falmouth—a magnificent garden for these Rhododendrons. It was 12 feet high and 15 feet through when I saw it about two years ago. Covered with the deep red flowers it must make a glorious picture.

**R. CAMPYLOCARPUM** is closely allied to the preceding; it is of similar habit, although perhaps not quite so strong a grower. The leaves are similarly glaucous beneath, but not so dark green above. An ample distinction is afforded by the

flowers, which are pale yellow. They are borne in a loose truss and are scented like honey.

**R. HOOKERI.**—In gardens this is a very rare plant. I have only seen it in flower once, and that was in the spring of 1888. It is a native of Bhotan, and on the Oola Mountain is said to form entire thickets accompanied by *Pinus excelsa*. It belongs to the same group as *Thomsoni* and *campylocarpum*. The leaves are oblong or oval, 4 inches long and rather glaucous beneath. The flowers are smaller and more numerous in the truss than those of *R. Thomsoni*, and are of a bright, but not so rich a red as in that species.

**R. CINNABARINUM.**—In "The Flora of British India" this name is made to include what have previously been known as *R. Roylei* and *R. blandfordiae*. The species is, indeed, a most variable one, having flowers of a brick-red, rich crimson, or sometimes greenish colour. They are all distinguished by the long narrow corolla, resembling a *Lapageria*. The leaves are small, pointed, of a dull glaucous green above, slightly ferruginous beneath; hardy near London.

**R. TRIFLORUM** bears some resemblance to the preceding in foliage, but the leaves are smaller and the flowers are yellow and more open. It is not so handsome a plant; said to be as hardy as *cinnabarinum*.

**R. KEYSI.**—A curious species, with flowers more like a *Correa* than a Rhododendron. They are brick-red, about 1 inch long, the lobes of the tubular corolla being almost straight and not spreading. The leaves resemble those of *R. triflorum* and *R. cinnabarinum*, to which species it is most nearly related.

**R. NUTTALLI.**—Individually the flower of this species is the largest of all Rhododendrons. As many as ten or twelve flowers are produced in one head, each one 6 inches in diameter, white, becoming creamy yellow in the centre. The flower is, indeed, like a large Lily. The species is of tree-like habit, reaching a height of 30 feet. It is of rather ungainly habit, and does not succeed so well under cultivation as many of the others do. The large rugose leaves are 8 inches to 1 foot long and about half the width. So far as I am aware it is not grown outside in Britain.

**R. MADDENI.**—A shrub 8 feet to 10 feet high with bright green lanceolate leaves. The corolla is pure white, bell-shaped, and about 3 inches across the mouth. It is known also as *R. Jenkinsi*. *R. calophyllum* is practically the same thing, but a varietal distinction is founded on the shorter calyx lobes and much smaller seed vessels.

**R. CAMELLEIFLORUM.**—A rare shrub of straggling habit, with long, thin pendulous stems. The leaves are very like those of *R. Maddeni*, but smaller. The flowers are pure white or faintly rose-tinted, and are curiously like some of the single-flowered *Camellias*. A well-defined ring of stamens encircles the pistil. The corolla is  $1\frac{1}{2}$  inches across, with five blunt, rounded lobes. I have only seen it grown under glass.

**R. DALHOUSIE.**—The true *Lady Dalhousie's* Rhododendron is one of the least common in gardens, what is frequently met with under the name being a hybrid between it and *formosum*. It is a shrub of scrambling habit, and in its natural state is nearly always seen growing as an epiphyte. About half a dozen flowers are borne in a head, the deeply bell-shaped, Lily-like corolla being 4 inches across, in colour white, tinged with rose, becoming yellowish with age. The elliptical leaves are 5 inches long, dotted underneath with minute scales.

**R. EDGEWORTHII.**—A very distinct and beautiful species, never getting beyond the shrubby state. It has long thin branches and comparatively small leaves (2 inches to 4 inches long), which are very rugose on the upper surface and woolly beneath. The flowers are over 4 inches across, the deeply lobed, rather flat corolla being pure white. Two or three flowers are borne together. This is a greenhouse species, and not one of the easiest to cultivate. In a state of nature it is frequently epiphytic on Pine trees.

**R. CILIATUM.**—A bushy plant which thrives well in sheltered positions near London. Its leaves are densely covered with hairs when young, becoming less so as they get older. The flowers are borne loosely in small trusses, and are rosy white on opening, becoming a purer white with age. I have seen this about 6 feet high in the Cornish gardens. It has been used for hybridisation, and amongst others *R. præcox* and *Rosy Bell* have been raised from it.

**R. FORMOSUM.**—There are two very distinct varieties of this in cultivation; the one has narrow leaves, in shape and size almost like those of an Indian *Azalea*; the other has them many times larger, obovate, and 5 inches long. Both have the margins ciliated. The flowers are in each variety white, although in the bud stage quite rosy pink. They are about 3 inches wide and as much in depth. *R. Gibsoni* and *R. Johnstoni* are forms of this species, differing chiefly in the larger leaves.

*R. anthopogon*, flowers sulphur-yellow; *R. glaucum*, flowers dull rose-purple; and *R. pendulum*, flowers white, are small-leaved dwarf shrubs, chiefly of botanical interest.

W. J. BEAN.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**LIFTING SECOND EARLY POTATOES.**—The whole of these may now be lifted, sorted, and stored away in the coolest place procurable. A shed with a north aspect is the best, more particularly for seed tubers, a south aspect inducing loss of weight and quality in those that are to be eaten and shrivelling, followed by an unsatisfactory sprouting of the seed in spring. A good plot from which this vegetable has been lifted should now be selected for early spring Cabbages, and if allowed to lie in a rough condition from now till a fortnight before planting takes place, a sweet condition will be ensured. Where the ground is liable to be infested with slugs in wet winters it will be well to spread over the surface a good coating of lime and soot, afterwards scuffling it in deeply with five-tined forks. Digging the plot a fortnight before planting and treading well afterwards will allow of a natural settlement, and give the plants a far better start than loose ground. This applies specially to light soils.

**YOUNG CARROT BEDS.**—Those who took the hint given some time ago and sowed a small bed or two in good soil, will now realise the value of such. For soups and flavouring generally, small Carrots are far in advance of older and more matured roots. If the grub has not yet attacked them it will pay to give another good sprinkling of wood ashes, soot, or burnt garden refuse between the rows, following it by a good soaking of water. Hoe between and hand-weed all young Carrot beds, and in cases where the dreaded grub has actually attacked the crop, procure a large tub capable of holding 100 gallons of water. Into this throw a bushel each of lime and soot, stirring it well round and allowing it to stand for a night. The following day well water by means of roses the Carrot bed. This will exterminate the pest and promote a healthy growth. I saw a bed some time since which had been so treated, and the effect was marvellous. It is important that the water used should be both warm and soft.

**GLOBE ARTICHOKE.**—It is many years since these made such a weakly growth, and those who would have the plants regain their original strength and vigour by another spring must give liberal treatment between now and the period at which the leaves and stems begin to decline. Should a number of small heads form—for they cannot but be small this summer—the whole of them must not be allowed to remain on the plants, and where the first mulch of manure has been washed away by repeated waterings or scattered by birds in search of food, a second must be given

without delay and as much farmyard manure of good strength applied as time and means will allow. Those plants which were raised from offsets in pots and transplanted at the end of May will require all the nourishment that can be given them and have any heads that may issue from the centres pulled off. These should make good useful bearing stools next year if carefully protected in winter.

**SPRING CABBAGE.**—Several weeks since I gave my reasons for refraining from very early sowings of this vegetable. I make my principal sowing at the end of the first week in August, Ellam's Early, Cocoa-nut, and Earliest of All being the varieties. Wheeler's Imperial and Mein's No. 1 are also good sorts for present sowing. If good seed is used it may be sown very thinly. Thick sowings are ruinous. My next sowing will be about the 25th, Enfield Market or some good variety of second early being included in it. As a rule, Cabbages for wintering in frames will be quite early enough if sown at the beginning of September. If sown earlier, large ungainly plants, which lift badly and are prone to run to seed after flagging from removal in spring, follow. Sow the red pickling Cabbage at the second sowing and with the third for frame protection.

**GREENS AMONGST POTATOES.**—Where through want of space planting Broccoli and kindred subjects amongst late Potatoes has been compulsory, the young plants must now be seen to, in order that they may not be ruined by the Potato haulm growing over and smothering them. Gently turn this back so as to admit light, air and rain to the roots. If the plants, through being partially shaded, have become at all weak and leggy, they must be made firm, at the same time bringing up a little soil to the base of the stems, as these cannot be mounded up like those growing on a separate plot. All late planted batches of Broccoli, Kale and general winter and spring stuff should now be earthed up to steady them, a little artificial manure being first sown broadcast amongst them. These late batches are frequently worth all the labour that can be spared them, helping out the supply in spring just at a time when scarcity would otherwise prevail.

**LATE-SOWN BEET.**—I pointed out some time ago the necessity for a late sowing of Beet in places where this root is eaten by itself at lunch, as large roots are generally objected to for slicing up. If the final thinning has not been given, see to it at once, and keep the rows free from weeds and the intermediate spaces frequently hoed to promote a clean, sweet growth. The coarse varieties which show white rings in their centres when cut are not fit for salad, and this fault is present in three parts of the so-called table Beets. I have this year again proved how well Beet does when transplanted, one bed in particular which was at first very patchy now being quite level through the speedy growth of the transplanted roots. This is worthy of note, as many people might think the experiment worthless.

**LETTUCE.**—If another transplanting is now made of various sorts on good moist land, it will probably keep up a good supply until the Cabbage varieties, sown as advised a week or two ago, are fit for use. These latter do not run to seed like the Cos varieties, and with much cooler nights and mornings remain in sound condition for a very long time. In planting, a slight drill is still advisable, as then a little soil can be drawn into it around each plant after watering, this preventing evaporation and excluding parching winds from the roots until well established. In all cases where a scarcity is apprehended it should be remembered that by leaving a percentage of plants on the seed bed and keeping them well watered, Lettuce may be cut a fortnight earlier than from the transplanted rows. Any Lettuces arrived at maturity may be taken up with care and laid in under a north wall, where they will keep for some time in an eatable condition. Of course, where other batches are coming on apace this is not necessary.

**RHUBARB.**—The erroneous idea is often entertained that in order to make the best jam and wine,

Rhubarb ought to be in a semi-withered condition. Those, however, who desire quality in either will do well to take the sticks which result from a secondary growth, which occurs in most vigorous Rhubarb beds and is now at its best. Some varieties too are better for jam and wine-making than others, the small-growing Prince Albert and Hawke's Champagne making a delicious preserve. Any seed stems should be taken off at once, so that the most may be made of the remainder of the season for strengthening and developing the stools for next year's work.

**SEED CROPS.**—Onions, Beet and similar vegetables being grown for seed must now be attended to in the way of supporting the growth. Stakes and cross rods are the best for Onion beds, stout rustic stakes being the most suitable for Beet, Broccoli and Kale. As the early sorts of Cauliflowers and Cabbages approach maturity protection by nets must be given, or birds will lay claim to the seed. Any stray Cabbage or Cauliflower on ordinary quarters showing for flower must at once be destroyed, as the probability is that any choice strains being seeded in the same garden will be crossed and spoiled. Opportunity should be taken on fine sunny days to destroy all the common white butterflies, as from their eggs issue the destructive green Cabbage caterpillars, although this fact is not generally known. J. CRAWFORD.

### FRUIT HOUSES.

**EARLY PEACH HOUSE.**—In most houses the trees will now have been cleared of fruit, and there should be no delay in doing the necessary cleansing should the trees be infested with red spider. The trees should be thoroughly coated with a thick solution of sulphur, which should be allowed to remain on a few days. Many trees if hard forced make a late growth if syringed freely after being kept dry for a time, and though it is necessary to frequently syringe after a hot day, it is not well to encourage late growth, and by dressing with sulphur, daily syringing is avoided. Abundance of air must now be given and the house kept as cool as possible, the ventilators being left wide open and the sashes removed, if possible, to thoroughly mature the wood. The roots should not be neglected, as these are most active, and in case the borders do not readily absorb the moisture they should be lightly forked over and given a good mulch of manure, thoroughly watering afterwards. I find cow manure, partly dried and broken finely, a splendid mulch for Vines, Peaches, and Figs on a light sandy soil. In the case of young trees growing too vigorously, surface dressings are not advisable, but old trees may be given liquid manure, failing a good mulch. There will be fewer complaints of unripened wood with early trees, and only in rare cases will it be necessary to keep up fire-heat to ripen sappy wood. Should the wood be at all soft, give a little fire-heat, with abundance of air. If the pruning advised in an earlier calendar was not carried out as soon as the trees were cleared of the fruit, there should be no delay in cutting out the old bearing wood, removing any useless spray or weak lateral growth. By doing this pruning now, very little will be required later on. I do not advise shortening back branches or shoots. This is best deferred till the trees have cast their leaves, as if done now it will cause a late growth.

**SUCCESSIONAL PEACH HOUSES.**—Much the same treatment will be required as advised in earlier houses. Unfortunately, very few Peach houses are constructed so that the lights can be removed entirely at this season, and if the air given is insufficient, there will be more difficulty in starting the trees next season. Should the trees be infested with thrips, apply quassia either in the form of a solution prepared from the chips with a handful of soft soap or, what is better, Bentley's prepared extract, a safe preparation which can be mixed for use in a few minutes. Tobacco water is also a well-known remedy and most efficacious. In cutting out the old bearing wood do not cut away any likely to be wanted for extension. Merely remove that which keeps away light and

air and will not be required to produce fruit next season.

**LATE HOUSES AND CASES.**—The fruit in these structures will be approaching the finishing stage and should get free exposure. Any misplaced fruits should be brought to the front by pieces of lath, giving abundance of food in the way of liquid manure or mulching. Late kinds of the Walburton Admirable type in unheated cases should get liberal treatment, the fruits being freely thinned. It is not too late to thin even yet any of the late kinds. The trees should get ample moisture in all parts of the house up to the finishing stage, and if the fruit is required for an early date, the house will be benefited by early closing. Syringe the trees freely and maintain a genial temperature. This treatment will assist in ripening the wood and greatly add to the quality of the fruit.

**REPLANTING PEACH HOUSES.**—It often happens when these trees are hard forced that there are losses by canker and other diseases, and when it is intended to renew these or destroy worn-out trees, the grower will find it advisable to select trees at this season for the purpose. All growers know the value of trees ripened under glass if the house is to be forced next season. Many of our large growers now make a speciality of growing such trees, and of course there is little trouble with them, as they are lifted yearly and in nice condition for removal. Others are obliged to resort to trees from open walls, and to these my notes refer. If these trees are gone over fortnightly and stopped, removing weak growth and developing the lateral or fruiting wood for next season, they will be in better condition and may be removed earlier than usual. I am an advocate for early lifting, as, provided due attention is paid to moisture, the wood will not shrivel. I have trees lifted with most of their leaves last October that never felt the shift and fruited well, having been prepared previously.

**NEWLY-PLANTED TREES.**—If these are young and not obtained from walls, but as small one-year trees from open quarters, generous treatment should be given. I do not hesitate to say many trees would be better if not cut so severely the first season or two. It is surprising what space a young tree will cover in one year if given every encouragement; in most cases the knife need not be used at all this season. The trees may be kept in shape by pinching foreright shoots and by giving ample room for lateral growth and main branches. I am aware many good cultivators do not care to lay in the lateral shoots from strong leaders, but shorten them back to the base. This is not necessary, as these will be of great benefit to the trees and will soon cover the space allotted them, thus saving time and, what is so important, prevent the main shoots growing so gross. There will be fewer insect pests where there is free growth, and in the case of trees which cast their buds badly I have known it to cease by allowing more freedom of growth. Food, moisture and a free circulation of air will mature new growth and plump up the buds for forcing.

**ORCHARD HOUSE.**—The trees that have been cleared of fruit and have made a fair growth may now be removed, as advised for Cherries in an earlier calendar. Peaches and Nectarines cleared of fruit may be treated liberally as regards food at the roots. As these trees absorb the moisture so rapidly, liquid manure should be given daily, and there should be no lack of clear water with a good mulch on the surface. A short time before removal the trees may be prepared for the change by twisting them round, and when taken into the open the roots should be well attended to in the way of moisture. The trees in pots require attention in the way of cleansing as advised for planted-out trees, and when removed into the open they should be syringed overhead in the afternoon. The trees trained to back walls should get all the exposure possible by removing the lights. Apples and Pears in pots will need liberal treatment for the next few weeks. The trees will take liquid manure twice a day, and every attention must be paid to the top-dressing,

and as the fruits approach maturity the supplies of food must cease, only giving clear water. It is necessary as the fruits attain maturity to support them either by pieces of net or stout muslin. Apples and Pears finish much better in the open exposed to the air and night dews when fully developed. They must be protected from birds, and if wasps are troublesome, a light covering of tiffany will be necessary.

G. WYTHES.

## KITCHEN GARDEN.

### POTATOES AND TURNIPS.

POTATOES are behaving very strangely, and what to do for the best with many of them is not easy to decide. Early and second early varieties planted comparatively early produced moderately heavy crops and matured before the rains commenced. There need have been no hesitation as to what to do with these. Instead of waiting till the haulm turned quite yellow, thereby inviting an attack of disease and giving all a chance of growing out directly a soaking rain fell, the better plan would have been to lift, sort over, and store before anything happened to the crop. Because the skins are not set hard enough for the tubers to be roughly handled without a slight disfigurement resulting is no reason why lifting should not take place, for the simple reason that early lifting impairs neither the quality nor the keeping properties of the tubers. In the southern half of this country the bulk of Ashleafs, Sharpe's Victor, Cole's Favourite, Early Regent, Early Rose, Puritan, Beauty of Hebron, White Elephant and other early maturing varieties ought ere this to have been lifted and stored, the exceptions to the rule being in favour of any planted late in April or in May. Those who failed to lift in good time now find that protuberation has commenced, and a few days' longer delay would have meant a considerable depreciation in the value of the crops. Last winter so many seed Potatoes were ruined by the severe frosts that there was a great scarcity at planting time. As a consequence many had to be bought; some turned out true to name, others were much mixed, and the breadths of the latter are very annoying to their owners, especially when quite late varieties are dotted among early maturing sorts. I yet advise lifting the latter at any rate, leaving the late Potatoes to grow for a time longer. Standing on the ridges and drawing the haulm to a certain extent save the crops from disease and for a time prevent premature sprouting, and may be practised with advantage if there is not time for lifting. Late Potatoes are growing strongly, and in most cases should be left undisturbed. Prior to the change to wet weather many of them had formed a surprising quantity of haulm, but few or no tubers were to be found under them. Both top and bottom growth is now going on briskly and the crops may possibly be extra heavy.

After experiencing such a difficulty in procuring sufficient planting tubers, it will perhaps be superfluous to advise that more than usual be saved for seed, but there are short-sighted people who never seem to profit by former experiences. For small or private gardens generally the short-topped, early maturing varieties are the most profitable, and far more of them should be grown for local markets, thereby obviating the necessity for retailers to send to Cornwall, Jersey, and France for so many. Always save abundance of medium-sized tubers for planting the following spring, and take good care of

them from the time they are lifted. Taking good care of them means keeping them stored thinly and in a fairly light and cool position to prevent premature sprouting, additional protection being afforded during the winter or whenever severe frosts are imminent. If it is thought desirable that seed Potatoes should be greened, let the greening take place in a dry, light shed, and not in the open, or the chances are a touch of disease may be taken with the colour.

There is yet another motive for early lifting and storing. An early clearance of the ground

ground, removing the rubbish, and making all fine, level, and firm. Drills can then be drawn 12 inches to 15 inches apart, the latter distance being desirable for the stronger growers, watering if at all dry, and then sowing the seed somewhat thinly. It will germinate quickly, and if the seedlings are kept well coated with either soot and lime or road dust, neither slugs nor Turnip fly will greatly interfere with them. Thin out lightly at first, and subsequently to a distance of from 6 inches to 9 inches apart, according to the variety. They will grow rapidly this season. Chirk Castle Blackstone,

a short-topped or strap-leaved form, is the best winter Turnip in cultivation. It is very hardy, and though the skin is black, the flesh cooks white and is very mildly flavoured. The yellow-fleshed varieties—notably Orange Jelly—are hardy and good, and any other white or coloured variety of which seed is at hand may also be sown.

In some districts acres of Potatoes and Peas are followed by Turnips, not, however, for either cooking or sale, but to be dug or ploughed in as manure. Year after year profitable crops are had from small holdings in the neighbourhood of Bromham, Wiltshire, farmed by working men, and green Turnips are all the manure given. Instead of the land lying fallow for several months it is covered by Turnips, these preventing the loss of fertility by evaporation, in this way saving far more than they take out, and, being duly dug or ploughed in, decay slowly and prove excellent as a fertiliser. It is the lighter or sandy soils that are most benefited by this and other forms of green manuring, and this knowledge

should also be turned to good account in many private gardens as well as market fields.

W. I.

*Rhododendron Keysi.* (See p. 104.)

admits of a successional crop of some kind being planted or sown with every prospect of its proving remunerative. Quite a variety of suitable successional crops could be named, and foremost among these I would place

#### TURNIPS,

which form a very acceptable vegetable during the winter, and are always in demand for flavouring. Then if a portion of the crop, and those undersized generally, are left on the ground throughout the winter, the bulk will give abundance of succulent greens which afford a good change with other green vegetables. No crop is more easily grown at this time of year. All that is necessary is to fork over the

**Endive—second sowing.**—The time has arrived when a second sowing of Endive should be made, the first sowing now being fit for thinning out. Sow principally the Broad-leaved Batavian, Fraser's Improved being about the best I have ever grown, although an old variety. A little seed of Moss Curled may also be included in the sowing, as, should the early winter prove mild, it may, even where frame room is scarce, stand uninjured in the open border, where it may be blanched with pots or slates, and thus still further spare the frame-protected broad-leaved stock.

When removing my stock of Endive into frames I always leave say every other plant on the border for first use, and an early cutting may be secured by leaving a good many seedlings on the beds when the rest are transplanted. Removal of the plants should not be done in wet weather, as, be the workman ever so careful, the foliage is apt to become besmeared with dirt, which remains on the plants throughout the entire growth and is apt to affect the salad bowl.

**Saving Bean seed.**—Where desirable to save seed of any choice variety either of the French or Broad section of this vegetable, the pods should be gathered from a mid-season crop, as if taken from later ones they are often insufficiently mature to produce good results the next season. After being gathered the pods should be placed in a cool, dry glass house for several weeks, after which the seed may be stored away in drawers or hung up in muslin bags in a perfectly dry place.—J. C.

**Transplanting Parsley.**—Where any frame or pit is not likely to be wanted for any other purpose till spring it would pay to make a sowing of Parsley in it, thinning out freely the young plants. Thus a supply of Parsley, let the winter be ever so severe, may be had. Where young Parsley needs thinning out, it is not yet too late to transfer the plants drawn out to any spare border which cannot well be used for other purposes, nothing tending more to ease a gardener's mind in winter than a knowledge that his stock of Parsley is abundant. Where any choice strain is being saved for seed the bed should be gone through and all small heads of seed removed in order to throw strength and quality into the rest; support also against wind.—N. N.

WINTER TOMATOES.

ATTENTION must now be turned to raising the plants to supply fruit in the months of November, December, and January, and as all varieties are not adapted for winter work, I would recommend Ladybird, and where a corrugated form is not objected to, the old dwarf Orangefield will be found to answer well, one good point in its character being its tendency to crop from the very lowest joints of the plant. Conqueror and the Old Red are also good. Sow the seed in small pots, and place in a comfortable temperature, allowing abundance of air from the moment the seedlings peep through the soil. When the seedlings are 3 inches high remove them to a frame, standing the pots on a hard ash bottom, and keep the frame somewhat close for a week, after which plenty of air must be given, the lights being entirely removed during fine days. Care must, however, be taken that heavy rains do not sodden the balls, especially just after potting, or these autumn Tomatoes will turn yellow and fail. Repot at intervals until the fruiting size is reached, namely, a 10-inch pot, practising firm potting and using a compost of good open loam, road grit in plenty, and a sprinkling of artificial manure, nothing answering better than bone meal. The use of farmyard manure, dangerous at any period, is doubly so in autumn, there being less sun to harden and solidify the growth. By the middle of September the plants may be removed indoors, a light, airy house where sufficient heat can be given to keep the atmosphere buoyant suiting them best. If the plants can be arranged pretty close to the hot-water pipes, so much the better, as the gentle warmth from these, coupled with a little front air day and night, will aid the first trusses to set their fruit and ward off the disease. If any fruits should set when the plants are in the frames and before receiving their final shift, do not remove them, as these will serve a two-fold purpose, first keeping growth in check and furnishing a nice gathering a month after the plants are removed under glass. Another thing that must be avoided in winter Tomato culture is closing up the house and throwing water about the floors and stages. This is simply ruinous; the drier and more arid the air the better the results, so

long, of course, as a parched condition of the same through fire heat is avoided. If at the time the plants are in flower the weather is extra dull and humid, it will be necessary to go over the blooms at noon and assist fertilisation with a brush or rabbit's tail. J. C.

**Staking late Peas.**—Peas of the Ne Plus Ultra and British Queen type sown about the second week in June will now be forward enough for supports. Bearing in mind the exceptional value of Peas during September and October, it will be well not to allow the least postponement of this operation, even if other work has to stand still for the time being. Once let the haulm become twisted and blown over by the wind, and it might as well be pulled up and thrown away. Use good stout stakes, as the growth of the taller late sorts of Peas is often rampant, especially in cool, moist autumns, they not unusually running up to a height of 8 feet or 9 feet. When the haulm has ascended to the top it will be safe to tie cross rods horizontally along each side, thereby enclosing it and preventing it from falling down and smothering the lower growth. Previous to staking draw a little soil up to the rows and, except on strong land, mulch with some lightish material to conserve the moisture. There is no need, however, of any extra manurial application for such late crops, as a harder and more wiry growth will better withstand mildew. If it is seen that too thick sowings were practised, it will be best to reduce the bulk of the haulm even now, as unless a sufficiency of light and air can penetrate to the interior, mildew and every other evil common to late Peas may be apprehended. Where for extra late dishes such dwarf sorts as Chelsea Gem and William Hurst have been sown and are now through the soil, all the extra care that may be bestowed on them will be well repaid.—J. C.

**Autumn Spinach.**—With cooler nights and days generally, a sowing of this vegetable may now be made with every prospect of the crop doing well. A few weeks ago I recommended that the plots both for this and the winter batches be specially prepared, so that the roots might not be devoured by wireworm. For this autumn supply I would recommend a west border, if such can be spared, south borders being more suitable for actual winter Spinach. Make the ground very firm and allow plenty of space between the rows. Sow the prickly variety not too thickly, and thin out freely immediately the seedlings can be handled. The sowings for a winter supply may be made about August 12 or 15 in midland and northern districts, ten days later being soon enough in the south of England, another sowing following this about the second week in September for spring supply. It is strange that winter batches of this vegetable should be so much more liable to the attacks of wireworm than summer ones. I think many gardeners make a great mistake in always sowing it on the same border, imagining that a south aspect is alone suitable for it. Even if the border is long enough to allow of a change of ground, it is apt to become Spinach-sick. The fact is, on ordinary soils not too retentive of moisture and that are kept in good heart, winter Spinach will thrive quite as well on open quarters; indeed, I think that from the first it grows harder and is better able to withstand the inroads of frost than Spinach on a south border. Even where all due precautions are taken in preparing the ground to ward off the dreaded wireworm, a continual watch must be kept as growth proceeds, this pest often attacking the plants when 3 inches high. In such cases I would advise the use of the mixture recommended in a recent calendar for the Carrot grub. I have proved that the round summer Spinach will grow equally as well in winter as the prickly variety and eats more juicy. Where room can be spared, I would advise a sowing of each to be made, the certainty of a crop thus becoming greater. One thing needful with both autumn and winter batches is moderation in picking at first. If all the larger leaves are picked off as soon as ready,

the plants sometimes get a check and are slow in producing afterwards: whereas piecemeal gatherings until the plants become strong and vigorous prevent this evil.—C. C. H.

STOVE AND GREENHOUSE.

MARKET PLANTS AT EDMONTON.

ALTHOUGH the charming groups of Ferns that are frequently seen at the R. H. S. meetings admirably illustrate the richness and variety of the great collection grown by Mr. H. B. May in his nursery at Edmonton, they cannot give the faintest idea of the enormous stocks of the popular market sorts that are growing in this nursery. One goes through house after house of Adiantums and Pterises, and sees them in countless numbers and in varied states from seedlings up to market plants in 4½-inch and 6-inch pots, each plant a perfect specimen of its kind. Every batch of plants is, as it were, a crop brought on to a certain state, then marketed to make room for more. Doubtless a very short period of life remains for tens of thousands of these Ferns after they leave the growers' hands, hence the constantly existing and, we may say, ever growing demand for them, as we noticed very great additions have been and still are being made to this establishment to meet the requirements of trade. But apart from this extensive culture of existing varieties for special purposes, other aims and interests are not ignored, as not a few really first-rate new and distinct Ferns have been raised or otherwise acquired and distributed from this nursery. As a market Fern the old Adiantum cuneatum still maintains its premier position, but preference is here given to a form of it named elegans, as it is hardier and grows more freely; to such an extent is this latter characteristic apparent, that in spring when batches of both are cut down the variety elegans outstrips the type in new and rapid growth. Two of the newer Adiantums, both charming and distinct as seen here, are A. elegantissimum with large, spreading, finely-cut fronds of the greatest elegance, and A. tenellum, which is more of the cuneatum type, but most distinct and robust. One house is entirely devoted to Adiantum Farleyense, which ever commands admiration from its rich luxuriance of graceful growth. Pterises have always been a feature of this nursery, and two varieties that originated here are now popular plants. These are P. cretica Mayi and P. c. nobilis, this latter an erect growing variety of remarkable substance and specially fitted for market work. A distinct advance in the crested forms is seen in the variety Mr. May is now sending out under the name of P. cretica Wimsetti and which obtained an award of merit at one of the early meetings this year. It is a tall and handsome grower, the tips of its long pinnales crested, as are those of other forms, but the broad pinnales branch laterally, and each of these side growths is terminated by a crest as well. There is no doubt it will become a popular kind, and it shows its distinctive character fully by reason of its robust and free habit of growth. P. Victoriae is a variegated variety, but really pretty, the pinnae having a distinct band of white down the centre margined with light green. This is comparatively new, but several different forms of it have already been obtained here, notably one called nivalis, which has fronds of a lovely shade of silvery white. Nephrolepis exaltata is one of the very best Ferns to grow in hanging baskets or suspended pots, and an enormous quantity of it is grown here.

*N. davallioides* is another first-rate kind with long and elegant fronds. *N. plumosa* is a charming crested form, and *N. d. multiceps* is most distinct, each frond being terminated by

June 16, 1894, is being tried as a market plant, and we saw three very large batches of it, the forwardest just coming into flower. Other plants now extensively grown are *Aralia*

blossoms of the Pelican Flower (*Aristolochia gigas Sturtevantii*), for which, however, a good-sized structure is necessary to show it off to the best advantage, while that at the head of this note (*A. elegans*) is well adapted as a climber for a small house, as the leaves do not obstruct much light and it flowers profusely. The blossoms, too, are so delicately marked, that a close inspection is necessary, and this, of course, is more readily done in a small structure than in a large one. The shoots of this *Aristolochia* are thin and wiry and somewhat sparingly clothed with pale glaucous green leaves. The flowers, on long stalks, have an abruptly bent tube, as in most other members of the genus, whilst the mouth of the flower is shell shaped and irregularly and quaintly marked with purplish red and creamy white in about equal proportions. The interior of the throat is yellowish, surrounded just at the mouth of the tube with rich velvety purple. The blossoms are without the disagreeable odour possessed by some of the *Aristolochias*, which is another point in its favour for small structures. It strikes very readily from cuttings put in at any time during the growing season, and so free-blooming is it, that I have seen pretty flowering examples in 5-inch pots. In this case the twining shoots were wound round a few sticks and then the plants flowered freely. In this way, however, they are not so effective as when grown on the roof of not too tall a structure. This *Aristolochia* is a native of Brazil and was first distributed in 1886. A coloured plate of it was given in THE GARDEN, June 19, 1886.—H. P.

*Rhododendron Dalhousie.* (See p. 104.)

a branched and spreading crest cut into tiny segments. Another delightful Fern for pots or baskets and unique in its graceful silvery white fronds is *Nothochlæna sinuata*. *Asplenium Mayi* is a handsome variety, having bold spreading fronds of great substance, the pinnae quite thick and fleshy, yet gracefully arching, finely cut, and of a shining deep green colour.

**PALMS**

are largely grown here, especially *Kentia Belmoreana*, which is by far the most popular of all Palms for market work, and was seen in countless thousands from germinating seeds through all gradations up to a considerable size. The largest plants, particularly handsome, being short in the stem and still retaining their first leaves, were clothed with foliage practically to the pot. *Cocos Weddelliana* was the next most conspicuous Palm in point of numbers. Crotons in great variety are remarkably well grown, and although all of the usual marketable size, most noteworthy for their fine colours, which we never saw brighter in plants of the size. Carnations in pots, chiefly tree varieties, are another feature of this nursery, all the best sorts in quantity, especially *Miss Jolliffe*, which in its particular colour still remains unique and indispensable. Several fine new varieties raised here were in flower, and we noted with satisfaction that instead of striving after great size, other more essential points have been considered, first of all a long and perfect pod which will not split. *W. Robinson*, bright scarlet; *The Shalzada*, deep crimson; *Henry Gibbons*, bright crimson; *Mrs. S. Segar*, full rosy pink, and *Firefly*, brilliant red, are all new kinds that will always bear flowers free from splitting or any defect of that kind. *Veronica Purple Queen*, of which a coloured plate was given in THE GARDEN of

*Sieboldi*, which, formerly given greenhouse or frame treatment throughout the year, is now treated entirely in the open air during the summer months, *Bouvardias* and double *Primu-*

*Rhododendron campanulatum.* (See p. 104.)

las for winter blooming, with *Erica hyemalis*, *Cytisus racemosus*, and *Hydrangeas* for the spring. ***Aristolochia elegans***.—There have been many notes concerning the huge, quaintly marked

**USEFUL WINTER PLANTS.**  
It is always gratifying for a gardener to know that he has a good healthy stock of winter-flowering plants coming on. *Chrysanthemums* are all very well so far as they go, but although, by striking the cuttings at various dates and growing them in small pots, they may be used for small vase and basket work in the drawing-room, other things are needed that will do service when the *Chrysanthemums* are over. How useful *Abutilons* are, *Boule de Neige*, *Darwini superbum*, and *tessellatum* being as good as any for winter use. These, if propagated in early spring and grown on in intermediate quarters until warmer weather warrants their removal to frames and finally to the open air, may be grown into nice-sized specimens the first summer, and if cut back the following spring and repotted when an inch of growth is made and given the same treatment as the newly-raised batch, will make large bushes that will come in most useful for table or sideboard work or even for grouping with other subjects at the foot of staircases, entrance halls, and similar places. The bright, distinct flowers of these *Abutilons* contrast most pleasingly with the glossy green foliage when well grown. A mixture of good fibrous loam, rather light than

otherwise, with a good percentage of leaf-mould and grit and a sprinkling of some approved fertiliser suits them well. If the plants become in the least pot-bound and another shift cannot be given, stimulants must be supplied, or the leaves soon turn yellow and fall. Scale and green-fly are rather partial to these plants, and soon bring about a sickly condition unless speedily removed. It is not all who have convenience for a good batch of winter-flowering Carnations, and unless ample time can be given to their wants during the summer months and a light airy house where they can be arranged close to the glass in winter, their culture had better not be attempted. At this season the plants, although standing in the open air, are liable to become infested with green-fly, this being difficult to reach, as the close overlying leaves at the tips of the growths shield it from all insecticides when applied in the ordinary way. I find the best plan is to go over the plants with tobacco powder, one man holding the growths open, while a second dusts them through a piece of tiffany or coarse muslin, syringing them well the following day. In watering the Carnations the happy medium must be aimed at, more particularly in the case of newly-potted plants. In times of heavy rains I have sometimes laid all the plants on their sides for a few days, as continued saturation will soon cause a yellow and sickly condition, some sorts, such as Miss Joliffe and Mlle. Carle, suffering sooner than others. Much feeding is not advisable, at least during their summer growth; in fact, I do not give liquid manure until the plants are in their winter quarters and well covered with bloom buds. The roots are very delicate, and I once saw a fine batch much injured by the man in charge giving stimulants of his own accord. A surface stir, to remove any accumulation of green and to admit air and sun to the roots, is necessary occasionally, and the watering should, where practicable, always be done by the same man. *Libonia floribunda* is a most useful decorative winter plant, and one that well repays good cultivation. Nice-sized plants in  $4\frac{1}{2}$ -inch pots may be had in one season by striking cuttings early in January, a few old plants being cut back and placed in a brisk heat at Christmas to supply them. These plants make capital bushes if repotted and treated liberally the second season. If kept in the same pots the second year they seldom do well, being free-rooting. Although requiring an intermediate temperature during the earlier part of the year, *Libonias* do best after the month of May in pits or frames, where they can be aired according to the weather. When left in a close stove atmosphere green fly is constantly attacking them, and the leaves often turn yellow and fall off. When in free growth an occasional dose of diluted liquid made from sheep or cow manure helps them much, also vigorous syringings when the pit is closed on sunny afternoons. They must be taken into a temperature of  $50^{\circ}$  towards the close of September. There are few better things for the decoration of a warm conservatory or for basket and vase work indoors; in the latter case, however, the plants must be frequently changed, or the blooms soon fall. Loam, a little dried cow manure, and silver sand suit them well. The old *Coronilla glauca* with its showy pea-shaped flowers is one of the most useful plants that can be named for this season, doing well under exactly the same treatment as *Chrysanthemums*, except perhaps that the potting soil needs to be used in a somewhat finer state. Cuttings strike readily if taken off with a heel as soon as a couple of inches of growth has been made, and the old plants last for many years if repotted occasionally and

top-dressed with good rich soil and manure. They may be left in the open air as late as *Chrysanthemums*, being then placed in a cool, light, airy position in the greenhouse or conservatory.

*Begonia fuchsoides* and *B. weltoniensis*, the latter a special favourite amongst those who have much indoor furnishing to do in winter, do best when potted in fibrous loam, a little peat, leaf mould, and silver sand or road grit, preferring, like the *Libonias*, a warm moist pit during the summer, where they can be treated to early closing and gentle syringings overhead. These will also bear and enjoy a little weak liquid manure once a week when the pots have become well filled with roots. *Eupatorium odoratum* and *E. riparium* are of very easy culture, rooting freely into a compound of loam, well-rotted manure, and rough sand. Plants which have grown one year should be cut freely back and repotted, cool treatment throughout suiting them best, with complete exposure from June to October. Although the *Eupatoriums* cannot be said to be very showy, the flowers are light and graceful, and last well in a cut state.

J. CRAWFORD.

#### Double zonal *Pelargoniums* in small pots.

—I have been surprised to see how profusely some double-flowered zonals have bloomed in a very limited amount of soil. A double white in a  $4\frac{1}{2}$ -inch pot had twenty good trusses, and I counted upwards of thirty trusses of a pink variety on a plant in a 6-inch pot, and one in a  $2\frac{1}{2}$ -inch pot carried fifteen good heads of bloom. They were potted just about a year ago for winter bloom, and have remained in a cool house, without change of soil, all through the spring, getting a dose of weak liquid manure from time to time. If I had to grow double zonals for conservatory decoration either in large or small pots, I should get them into a root-bound condition before they commenced to flower. They make stout, short-jointed wood, which produces flower-buds more freely than when the roots have fresh soil to work into during the spring months.—J. C. B.

***Ruellia rosea*.**—Like many other *Acanthads*, the flowers of several of the *Ruellias* are very attractive, and the above-named species forms just now a bright and showy feature in the intermediate house. The flowers, which are borne in open clusters at the points of the shoots, are larger than those of some *Ruellias*, the tube being about 2 inches long and the expanded mouth of the blossom nearly  $1\frac{1}{2}$  inches across. The colour is a bright magenta-rose. True, the individual flowers do not remain long in beauty, but a succession is kept up from one cluster for a considerable time, and the plant grows and flowers continuously throughout the summer. Like all of its class it is of easy propagation and culture, for cuttings strike root readily enough. As is the case with many of its more immediate allies, the best results are obtained from young plants. A few other species of *Ruellia* well worth a place in any garden are *R. Herbsti*, *R. macrantha*, *R. Portellæ* for winter flowering, and *R. speciosa*.—H. P.

**Soaking seeds.**—On p. 55 some very good advice is given with regard to Everlasting Peas, and that is to soak the seeds in water for eight or ten hours (especially if the seeds are old) previous to sowing them. Such advice might be given concerning many other seeds, especially those with a particularly hard covering that take a long time to germinate. Cannas, for instance, grow in a very irregular manner if there is not a brisk heat at command, and to assist them in this respect one often hears the advice given to file the seeds previous to sowing them; whereas all the trouble and risk of injury to the embryo may be obviated and the same ends attained by soaking them for twenty-four hours in water which is slightly warm—that is to say, at about a stove tempera-

ture. I generally fill the pans in which the seeds are placed with water from the stove and stand them for twenty four hours on a shelf in the same structure, as by so doing there is not the risk that attends the use of hot water. I have treated the seed of several other classes of plants in the same way, the results being altogether satisfactory. Thus some seeds of tropical *Erythrinas* when soaked germinated in about a month, while others not soaked absolutely refused to grow. Some Australian *Acacias*, too, behaved in much the same way. One caution that must be particularly observed after seeds that have been treated in this way are sown is to see that the soil is not allowed to get dry, otherwise irreparable injury may quickly result.—T.

### IN A GLOUCESTERSHIRE GARDEN.\*

Any man who walks the mead,  
In bud, or blade, or bloom may find,  
According as his humours lead,  
A meaning suited to his mind.

"Day Dream."—TENNYSON.

In April of the present year I made a very pleasant pilgrimage to the historical garden at Bitton Vicarage, in Gloucestershire, and was amply rewarded. The garden is not a large one, being about an acre and a half in area, and in shape a parallelogram, or double square. As its genial owner tells us:

It lies on the west side of the Cotswolds, which rise, about half a mile away, to the height of 750 feet, and about 15 miles to the south are the Mendips. These two ranges of hills do much to shelter us from the winds, both from the cold north and easterly winds, and from the south-west winds, which in this part of England are sometimes very violent. I attach great importance to this kindly shelter from the great strength of the winds, for plants are like ourselves in many respects, and certainly in this, that they can bear a very great amount of frost, if only the air is still, far better than they can bear a less cold if accompanied by a high wind.

The garden then has the advantage of shelter; it has also the advantage of a good aspect, for though the undulations are very slight the general slope faces south; and it has the further advantage of a rich and deep alluvial soil, which, however, is so impregnated with lime and magnesia that it is hopeless to attempt *Rhododendrons*, *Azaleas*, *Kalmias*, and many other things, and it has the further disadvantage of being only about 70 feet above the sea level, which makes an insuperable difficulty in the growth of the higher alpine. On the whole, the garden is favourable for the cultivation of flowers, and especially for the cultivation of shrubs, except those which dislike the lime.

The garden is in many ways an ideal one, lying deep down in a happy valley and forming with the noble old church the focus spot of an old world village. In some of the cottage gardens passed on my visit I saw the common white Lily in splendid healthy clumps and masses, and the quaint tortoise-shaped Yews in front of one creeper-laden old cottage seemed like relics of mediæval England. I saw the Vicarage garden on a showery April day with larks singing and swallows flitting around the house and amongst the trees, and the cuckoo and cornrake were vocal and happy in the adjoining meadows of lush grass and budding hedges. It is a quiet, peaceful garden of grass and trees and simple borders, and every nook and corner has its appropriate flower; in a word, it is just such

\* "In a Gloucestershire Garden." By the Rev. Henry N. Ellacombe, M.A., Vicar of Bitton and Hon. Canon of Bristol. Illustrated. Loudon: Edward Arnold, 37, Bedford Street, Strand. 1895.

a garden as one would expect a scholar to possess who has sympathy for all that lives or breathes and who has given us such a book as "The Plant Lore and Garden Craft of Shakespeare" in addition to the exquisitely reserved work now before us. The garden at Bitton Vicarage is no new garden, for it was famous more than half a century ago, when Haworth and Herbert, Anderson, Falconer, Sweet, Baxter and others took such an interest in bulbs and hardy flowers. By the same token it is by no means a new-fangled garden; there is all due and proper keeping, but it is patent to any plant lover that its owner thinks more of seeing his plants happy and healthy than he does of any unnecessary trimness or of neat and formal precision. Nay! he has even some sympathy and reasonable toleration for the more useful and beautiful garden weeds.

But my object is to deal with the book before me, and I can promise all true gardeners much pleasure in reading its well-printed sheets. The book consists of 302 pages, including a good index, and it is divided into two parts. The first part is devoted to a pleasantly-written calendrical record of the months of the year, with notes on the seasonable flowers, and trees, and birds, &c., that go to make a garden such a perennial delight. The second part comprises some charming little essays on spring flowers, shrubs, Roses, Lilies, climbing plants, garden walls, autumn leaves, Palms and Bamboos, Brambles and Thistles, trees in the garden, birds in the garden, garden associations, garden lessons, and parsonage gardens *ad clerum*. The illustrations are mostly very pretty ones of the allegorical kind, and I believe I have seen them in another place; still they are a welcome addition to a good book. The scholarly and suggestive little volume owes its existence, we are told in the preface, "to certain papers of mine which were published in the *Guardian* during the years 1890 to 1893," and it forms another stone in that beautiful arch of garden books that have appeared of late years, such as Mr. Bright's "Year in a Lancashire Garden," the chronicle of a year chiefly in a garden; Miss Hope's "Gardens and Woodlands"; the Hon. Mrs. Boyle's "Days and Hours in a Garden"; and Forbes Watson's "Prose Studies of Flowers"—all delightful successors to Alphonse Karr's classical "Tour Round my Garden" and of Charles Dudley Warner's "My Summer in a Garden," two books that should be read by everyone who tills the soil.

We gardeners by profession must all tender our grateful thanks to Canon Ellacoube for his delightful contribution to the literature of the garden, and even if the work contained nothing but the last essay on parsonage gardens we should feel a threefold link of twisted golden wire between himself and the ever venerable George Herbert, for what Herbert did not attempt for us the present occupier of classical and beautiful Bitton has well supplied, and I hope the author will pardon the reprinting as a quotation of what I believe to be the literary gem of the work, viz., the *ad clerum* essay on parsonage gardens.

I often regret that George Herbert did not add another chapter to his "Country Parson," and tell us his views of the parson in his garden. With his high views of the importance of the parson's character showing itself in the minutest details of daily life—"he leaveth not his ministry behind him, but is himself wherever he is"—it would have been pleasant to have been taught by him how the parson could manage his garden, not only "in the knowledge of simples, wherein the manifold wisdom of God is wonderfully to be seen," but also "like a parson, thus raising the action

from the shop to the Church." That he had not only a love of flowers and gardening, but also a full knowledge of them, is shown by many passages in his poems; and in the chapter on "The Parson's Completeness" he considers a knowledge of plants to be necessary in a parson—that he would be incomplete without it.

And a country parson without some knowledge of plants is surely as incomplete as a country parsonage without a garden. Certainly he deprives himself of much pleasure, and in some respects of usefulness. I am thankful that my own lot has been cast for me in the country, yet I can fully understand and appreciate the actual pleasure which an active earnest clergyman finds in the crowded, unlovely streets, and even in the slums of a densely populated city cure, and I can even sympathise with his dislike to the quite stagnation (as he would call it) of a country parsonage; but I cannot understand a clergyman whose lot has been cast in the country, and who has accepted the lot, shutting his eyes to all the beauties which surround him and which come up to his very doors, and to whom the change of seasons, and even the changes from day to day that he must see, are only changes from one kind of dullness to another. Such a man must be wretched in a country parsonage, but I have not much pity for him.

I need not describe the ideal English parsonage and its garden. It has been described over and over again, and indeed it has passed into a proverb, so that when a house is described as "like an ordinary English parsonage," as Wordsworth's home is described, we know at once what it means. We picture to ourselves a building of moderate size—not pretentious—neither a mansion nor a suburban villa (*Parvas sed apta domino* is the inscription on an old Wiltshire parsonage), and of an old foundation; yet with many additions and accretions of different dates, each bearing some impress of the successive owners; and the garden is of the same character, often standing (and always in the ideal parsonage garden) near the church and churchyard, so that the church forms the feature in the garden. The parsonage garden is not large, seldom exceeding two acres, and more often not exceeding one, with little glass, and no pretension to a high-class garden, but with a good spread of old lawn and many old trees and flowering shrubs, all suggestive of repose and quiet, pleasant shade, and freedom from the bustle of the outside world. The parsonage garden some years ago was a home for hundreds of good old-fashioned flowers, but I am afraid no gardens suffered more from the bedding craze, which swept them clear of all their old long-cherished beauties, and reduced them to the dull level of uniformity with their neighbours' gardens, or to miniature mockeries of Trentham or Cliveden. That craze has to a great extent passed away, and the parsonage gardens are gradually recovering their old features, and fortunately they are able to do so more easily than some other gardens, because in most of them the trees and shrubs were spared, and have been a valuable help in the restoration to a better and more healthy style of gardening, and one more in keeping with the character of the country parson's garden. There are hundreds of such good old gardens scattered throughout England, of which Charles Kingsley's garden at Eversley and White's garden at Selborne are well-known typical examples.

That such gardens are a real pleasure and refreshment to the owners we all know, and they are none the less so when the refreshment is taken in hard manual labour, for many a country parson can bear witness that "the very works of and in an orchard and garden are better than the ease and rest of and from other labores" (William Lawson, 1608). But I said also that parsonage gardens had their usefulness, by which I mean they may be made useful to the clergyman in his parochial work. How this may be done I need not say at any length, because the method that would be very useful in the hands of one would be perfectly useless in the hands of another. I

would only say generally, that the love of flowers and gardening is so universal amongst the English peasantry, that a country parson will often find a better introduction to a cottager through his garden than by any other means. And though the love of flowers is so universal, and the garden may be such a useful adjunct to the cottage, yet there is very great ignorance of the right principles of gardening, and the parson may be of great use to his poorer neighbours, not only by teaching, but still more by showing them better ways in his own garden. For the parsonage garden gate should be always open, and every parishioner welcomed; there need be no fear of any undue advantage being taken of the free permission to enter—the one difficulty will be to induce them to come in. And the parson may do much to brighten the gardens of his parish, and so to increase the interest in them by giving plants from his own garden. I have for many years been a cultivator of hardy plants, and have been able to gather together a large number of species; and I was long ago taught, and have always held, that it is impossible to get or keep a large collection except by constant liberality in giving. "There is that scattereth and yet increaseth," was Solomon's experience, and it certainly is so with gardening; and the parson who is liberal with his plants will find the increase not only in the pleasant intercourse with his neighbours, but also in the enlargement of his own garden, which thus spreads beyond his own fences into the gardens of the cottages. Some clergy can do more than this by giving actual instruction in the wonders of plant-life, as was done some years ago most successfully by Mr. Henslow, and also by Mr. Dawes, the Dean of Hereford, who gave object lessons in his garden at King's Somborne; but this requires a special knowledge, and these two men were specially gifted with great knowledge, and with the happy power of imparting their knowledge to others.

There is one way in which I am sure the country parson might make his garden useful to himself in his ministerial work:—

I am not in the least ashamed (says the Rev. John Laurence in "The Clergyman's Recreation" in 1714) to say and own that most of the time I can spare from the necessary care and business of a large parish, and from my other studies, is spent in my garden, and I cannot but encourage and invite my reverend brethren to the love of a garden, having myself all along reaped so much fruit both in a figurative and literal sense.

The figurative fruits are the spiritual lessons he had learned from his flowers and garden; and I think the old writers and the old gardeners were more alive to these lessons than we are now. St. Francis de Sales was very fond of drawing his illustrations from flowers, and his notices of flowers and their lessons have been collected into a "Mystical Flora." Joachim Camerarius, an excellent botanist, published in 1590 a "Centuria of Emblems" from plants; and with its pretty plates and excellent scholarly and religious descriptions it makes a charming little volume. In 1657 Ralph Austin, "practiser in the art of planting," published "The Spiritual Use of an Orchard or Garden of Fruit Trees set forth in divers similitudes between Natural and Spiritual Fruit Trees," in which, though the similitudes are often far-fetched and the lessons strained, there is much that is well worth reading. In our own day, "The Catholic Florist" (1851) is a pleasant little book on the spiritual lessons of flowers, and their associations with different saints and saints' days, though sadly marred by fictitious quotations; and later still we have had similar lessons pleasantly taught us by Mrs. Gatty and Mrs. Ewing.

Much might be said on the great pleasures that the science of botany will give to a country life, and much more might also be said on the special advantages of a knowledge of the science and the practical uses of a garden to the country parson, but I will content myself with some words of others who have written on the subject. I have already mentioned "The Clergyman's Recreation," by Laurence. It is a good little book, but, except in the preface, has little specially for the clergy. The preface is, however, written *ad clerum*:—

To recommend the art of managing a garden to those of my own order, the clergy, not to make them envied by magnificence, but to make them happy by loving an innocent diversion suitable to a grave and contemplative genius. . . . This, I suppose, most people will allow, that as there are some sports and exercises not suitable to a divine, so gardening is a very agreeable and commendable recreation—viz., pruning, planting, sowing, grafting, and inoculating, and sometimes digging, *ad ruborem*, but not *ad sudorem*.

In 1796 "Three Dialogues on the Amusements of Clergymen" was published, professing to be the views of Bishop Stillingfleet communicated to Dr. Josiah Frampton. It is rather an amusing book, and can scarcely be taken seriously, but is quite worth reading. All amusements are more or less forbidden, except battledore and shuttlecock in the tithe barn. Gardening naturally forms one of the subjects of discussion, and he has little to say about it except that "there cannot be a more clerical amusement," but he gives the good advice that the clergyman should try to make his garden the best in the parish, a model garden to his neighbours.

But the best book on clerical gardening is "The Manse Garden," a book published nearly seventy years ago, and now, I believe, out of print, but well worth reprinting. The author was the Rev. N. Paterson, at that time minister of Galashiels, and afterwards a leading member of the Scotch Free Kirk. It is altogether a delightful book, full of quaint sentences, shrewd good-sense, and quiet humour, and the cultural directions are admirable. I mention it more particularly here because throughout the book the clergyman is never lost sight of, and though written for Scotch ministers and Scotch manses, it is equally suitable for English country parsons and country parsonages. The one chapter on "The Minister's Boy," which concludes the book, will come home to many an English country parson. There are many passages which I should like to extract showing the pleasant humour and practical character of the book, but I must content myself with one in his more serious strain as having a closer reference to my subject, and showing something of the ministerial aspect of the book:—

You will find in the very nature of the work a new interest communicated to your life, and which, relieving the pressure of cares and lightening the burden of toil, will tend to no worldliness of spirit. Thus conferring as well as receiving good, and incurring no evil, let our gardens and every corner of our glebes be adorned; and if we have to lament, on the part of those having large possessions, that too little is done, let us at least set an example, though it be but in the model style, and have our home a paradise of fruit and flowers, of shelter and shade, endeavouring still to make the place more worthy of ourselves, and ourselves more worthy of the place.

One point must not be left unnoticed. It seems almost unnatural for a country clergyman to be without some love of flowers and gardens; and the study of them comes recommended not only as a refreshment and from its practical usefulness, but also for its scientific and literary associations. Yet it has its snares, of which the chief is that it may become too interesting and too absorbing. Its very innocence may help on and even conceal the snare; but the snare is there as it is in everything else in this world, however good.

F. W. BURRIDGE.

#### POSITION OF HOT-WATER PIPES IN FRUIT HOUSES.

THE position of hot-water pipes in vineries, Peach, and other fruit houses has, I think, a very important bearing upon the vines and fruit trees growing in their vicinity. Formerly they were kept all together and principally round the fronts of lean-to houses, a single flow and return being taken from the back under the door-sills, and then branched into two flows and the same number of return pipes. Then came a change in the style of houses built, three-quarter span-roofed and span-roofed structures largely

superseding lean-to's. This necessitated an alteration in the system of arranging the hot-water pipes, a greater distribution, rather than massing them together, being practised, and so well has this been found to answer, that market growers now-a-days favour that arrangement for small as well as large houses. When the flow pipes are kept well apart from the returns and only a few inches higher, a much better circulation is maintained than formerly, the flows seldom becoming many degrees hotter than the returns; whereas by the old arrangement there was far too much disparity between them. This is a decided advantage in favour of distributing the pipes, nothing proving more prejudicial to plant life than being confined in an atmosphere from which a few over-heated pipes have extracted the moisture. More often than not these over-heated pipes are very near to the stems, and who shall say that much harm has not resulted from this proximity? If the stems are not injured, it is yet very certain that innumerable bad attacks of red spider have started immediately over the hot water. It is from this point of view, or the effect of any arrangement of hot-water pipes, that I propose to base my arguments for or against any particular method, leaving the more debateable portion of the subject, viz., the why and wherefore of any particular system of heating failing or succeeding, to those of a more scientific turn of mind.

That much good fruit has been, and still is, grown in vineries and other fruit houses where the pipes are massed near the fronts of the houses cannot be denied, and for some reasons that plan can still be recommended. Where so many have erred is in not keeping them well away from the walls, and at least 6 inches clear of the border. When Vines have to be brought in from an outside border, and there is only just enough space to keep them clear of the hot-water pipes, that is bad enough, but when not more than 6 inches separates the pipes from the wall, and Vines are planted in an inside border at the back instead of the front of the pipes, then there is a great blunder committed. In my first place as head gardener I found the Vines in that predicament, and, what made matters worse, the return pipes were half buried in the border. As a consequence all the surface roots that attempted to form never got beyond the pipes, and, as I found them, were so many blackened sticks. Watering every time I entered the house did not mend matters much, and it was small matter for surprise that a great inside border was next to useless, the bulk of the Vine roots being away out foraging for themselves. Since then I have come across numerous instances where concentrated as well as single pipes were far too close on the border or else much too near the stems. In some cases the borders are quite humpbacked, the lowest parts being near the pipes along the fronts; and in the centre of the house. Little cause for wonder is it that Vines or any fruit trees thus circumstanced fail to do well owing to want of moisture at the roots. Once the hot-water pipes dry the soil immediately about them, trying to remoisten it appears to be a waste of labour. The remedy lies rather in raising the pipes and a change of soil. Unfortunately, shifting pipes with their joints packed in the old-fashioned way, or with rusted iron filings, many of which are already cracking or on the point of doing so, owing to the expansion of the rusting iron, is a very ticklish and, in the case of concentrated pipes, a very difficult proceeding, but single rows with expansion joints, or stopped with india-rubber collars only, can be raised gradually and safely. It does not cost so very much to re-arrange the hot-water pipes, but many gardeners have to do the best they can with existing arrangements, as little extra expense being incurred as possible. If, then, the pipes cannot be raised or re-arranged, the best way out of the difficulty is to lower the border so as to bring it to a lower level generally and well away from hot-water pipes. It is level and not sloping borders that are wanted inside houses, nothing being gained by sloping to either the front or back, while slopes are a great hindrance to watering operations.

Hot-water pipes, wherever located, are almost certain to be in the way sooner or later. If they are not, then they are fixed where some or much of the heat given off is wasted. Where, perhaps, they are least in the way, at the same time doing the least harm, is when concentrated not less than 3 feet away from the front walls of vineries, a trellised pathway coming next to the pipes. This arrangement admits of inside planting being done properly, and if the pipes are kept well clear of the border, the roots will spread uninterruptedly into the body of the house. In this position, again, lifting and relaying the roots in fresh soil can be done without much difficulty. Against this plan we have the fact that distributed pipes heat more equally, but at 6 feet or less apart all over the house they are much in the way at times, and it also means the construction of a considerable number of brick piers for supporting them, other than where they can be slung up, market grower's fashion, to strong wooden roof supports. Plenty of these distributed pipes are arranged far too low. If scarcely clear of the surface at the outset, the soil may sink quite clear of them in a few months, but market growers' borders do not sink a great deal, but, on the contrary, liberal surface additions soon half bury low-lying pipes.

In Peach houses hot-water pipes are more often in the way than they are in vineries even. They ought never to run just in front of the stems of the trees, not only because it is bad for the stems and the foliage, but more especially they make it very awkward for lifting and transplanting the trees at any time. I have helped to move scores of trees that had nearly all their roots below and the branches above the pipes, and in order to get the tree clear of the impediment, the top had to be depressed to near the ground, and the roots drawn out and over the pipes in the best way we could manage. Moving with a ball of soil about the roots under such circumstances was quite out of the question. It was equally awkward when large trees were brought in from an adjoining house or from the outside and replanted. If the pipes must run near to the front wall, then I would advise planting trees with a clear stem long enough to reach to the roof trellis and well away from the fronts. Some of the finest trees in the country, including those, if I remember right, at Syon House, are of that description and planted as I have just advised. In any case care should be taken to so arrange the hot-water pipes as to give a fair clear course to the trees and their roots, so that there be no difficulty in keeping the borders well moistened or in lifting whenever necessary.

In comparatively narrow Cucumber and Melon houses I have tried arranging all the top heat pipes against the front and back walls, and have also arranged them in separate rows, the flows running very close to the back walls, and the returns on the top of the walls on each side of central sunk path. The heat is kept up better by the latter arrangement, and none of the pipes get so hot as the flows are apt to do when the returns are immediately under them, red spider being less troublesome accordingly. Distributed pipes in Tomato houses 14 feet and upwards in width are somewhat in the way of trenching and cropping with Potatoes and Kidney Beans by way of "snatch" crops, but I have tried concentration and also distribution, and have somewhat reluctantly come to the conclusion that the former plan is the better for the Tomatoes. So very evident is this, that distribution of the pipes is taking place in several houses where they were previously arranged one above another. W. IGGULDEN.

**Notes from Ware.**—Now that the various plants in the garden and pleasure grounds have had time to recover, one will be better able to form a correct estimate as to what effect the two extremes of cold and heat had on shrubs, Roses, &c., in the comparatively short space of six months. The deaths among Roses in this part of the country are few, the Teas having suffered most, and in fact are still suffering, for scarcely a week passes but I notice a branch on one or other of

the varieties going. This is also noticeable on the cluster varieties, they having been weakened in the first instance by the frost, and have been unable to keep up that vitality required to carry them over the growing and blooming stages under the all-absorbing influences of excessive heat and drought. The Hybrid Perpetuals have got over the difficulty very well, but the flowering period has been of short duration. The various kinds of shrubs have been more or less crippled; some have never started into growth, viz., *Laurustinus*, *Aralia Sieboldi*, newly-planted *Mahenias*, *Andromedas*, *Euonymus variegatus*, *Garrya elliptica*, *Hydrangeas*, *Olearia Haasti* and *Veronicas*. *Cedrus Deodara* was rendered quite unsightly by the frost, followed by a scorching sun. The *Sequoia sempervirens* also looked very much injured. The Evergreen Oak looked as if it had succumbed altogether.—A. WALLACE, *Poles Gardens, Ware*.

## NOTES OF THE WEEK.

**Carnation Duchess of York.**—I was much struck with this pretty Malmaison pink self, which is in excellent condition at Jackman's nursery, Woking. The blooms are of medium size and well formed, as well as highly fragrant. It grows freely—a necessary point in the case of a border variety.—H.

**Gladiolus brenchleyensis and the Cape Hyacinth** planted in mixture fill a very large round bed at Kew and make a fine display of colour, effective even at a considerable distance. The arrangement, too, is suggestive, as there are many good hardy flowers worthy of the same bold treatment if rightly selected and suitably planted.

**Eucryphia pinnatifolia.**—This handsome shrub withstood the past winter in the open at Kew, and a group of it is now conspicuous with many fine flowers. They are like large single Roses, but have thick petals of a pure white colour and a prominent tuft of long graceful stamens. So beautiful a shrub is worthy of a good place, and it is all the more valuable for its late season of flowering.

**Gentiana saccardensis** is a charming species, now flowering and apparently quite at home in a poor stiff soil. It has some resemblance to *G. aclepiadea*, producing its flowers from the axils of the leaves upon the upper half of the stem, but is easily distinguished from this latter species by its clear bright blue flowers of a rich and exquisite shade of colour. Such a beautiful Gentian ought not to be so rare in gardens as it is.

**Magnolia glauca**, which has been recently noted as flowering at Knap Hill and Kew, is also in bloom at Stisted Hall, Braintree. It is 16 feet high, the trunk measuring 28 inches in circumference. Other *Magnolias* flourishing here are *M. Seoulangiana*, 8 feet high; *M. macrophylla*, 30 feet; and *M. conspicua* (Yulan), a trained specimen on a wall 10 feet in height and 11 feet in breadth.—B. ROGERS, *Stisted Hall, Braintree*.

**Arundinaria nitida** is a graceful and most distinct Chinese Bamboo now very conspicuous in the Kew collection, where it weathered the winter as well as any kind. It has long, slender cares, well clothed with small narrow leaves, whilst those of the present season's growth that have not yet cast their sheaths are of a distinct purplish hue. It is a most noteworthy addition to the really hardy kinds.

**Hypericum Moserianum** should become a popular dwarf shrub, as it is as free in growth as the old *H. calycinum*, but much more beautiful and lasting in bloom. It looks well at Kew, especially in one bed that is filled entirely with it—a sheet of rich colour with hundreds of buds yet to expand. A distinct feature of its flowers is that the petals remain and keep their fresh bright colour after the stamens have fallen.

**The Shrubby Cinquefoil** (*Potentilla fruticosa*) is generally recommended as a shrub for

dry banks, but we were charmed with a little bed of it on the grass at Kew. The verdure of the surrounding grass seemed to add much to its beauty, and it might certainly be grouped with advantage in good soil away from larger shrubs. It blooms profusely over a long season, and the flowers, though small, are most effective in their rich yellow colour.

**Symphandra Kaufmanni**, mentioned at p. 76, should be *S. Hoffmani*. It was named in honour, I believe, of Lt. Hoffman, of the Austrian army. In addition to its being a good hardy border plant, though only of biennial duration, it is a first-rate wall plant—in fact, a good deal of my stock is now permanently located on an old stone wall, to which it has moved from the border; a mortar joint seems to supply all its needs. This plant has also been distributed under the name of *Campanula sibirica*—T. SMITH, *Newry*.

**Primula capitata.**—A little group of this fine Primrose is the most attractive feature at present in the rock garden at Kew. It is beautiful alike in leaf and blossom, its mealy leaves spreading out over the ground, and its dense heads of flowers borne erect on stout stalks. Its flowers are of the richest purple colour, varying in depth of tint, but always charming in contrast with the white mealy buds. It cannot be called a good garden perennial, but it is advisable to raise a batch each year, so as not to be without so fine a species, whilst its late flowering is another point in its favour.

**Tufted Pansies from Scotland.**—Mr. J. Forbes sends us from Hawick a nice fresh lot of these charming flowers, comprising the best of the older kinds, like *Duchess of Sutherland* and *Marchioness of Tweeddale* and the new *Violetta* kinds in rich variety and varied colours. Some of the best of the latter were *Cordelia*, cream-white, with rich yellow eye; *George Lord*, deep rich yellow; *George Muirhead*, pale yellow; *Sweet Lavender*, mauve; *Blush Queen*, a delicate mauve; *Picotee*, white, with faint blue edge; *Ophir*, yellow; *Jennie Turnbull*, lavender, with white eye; *Oriole*, pale primrose; *Gnome*, cream, shaded golden yellow; and *Blush Queen*, delicate mauve.

**Fraxcos at the Birmingham Botanic Gardens.**—I have rarely seen *F. ramosa* in better form than it is at the present time at the Botanic Gardens, Edgbaston. It has thrown up very strong stems, bearing huge branched spikes of pure white flowers, which are very attractive. *F. sonchifolia* (the Sow-Thistle-leaved *Fraxcea*) is worthy of culture, though not so showy as its relative. The spikes are dwarf, unbranched, pink in colour, with a dark spot towards the base. *F. appendiculata* is often confounded with *F. ramosa*, but it is quite distinct from it, the flowers pale red, and also marked with a darker spot on the petals, the racemes of bloom compact. All three are very attractive greenhouse plants.—R. D.

**Delphinium cardinale and D. Zalil** are both flowering in the herbaceous grounds at Kew. *D. cardinale* grows very tall, and has bright red flowers almost identical in size, shape, and colour with those of the dwarf *D. nudicaule*, but in its thin and scattered growth there is not much to recommend it as a garden plant. *D. Zalil* is about a yard high, and, branching freely, bears pretty spikes of pale sulphur-yellow flowers. From what we have seen of the new yellow-flowered hybrid varieties there appears a strong resemblance to this species, which may probably be one of their parents. If we could get the colour of *D. cardinale* into good perennial kinds it would be a great gain.

**The weather in West Herts.**—During the past week the weather has remained, as a rule, cold for the time of year both during the daytime and at night. The temperature of the soil at 2 feet and 1 foot deep now stands at 62°, having fallen 2° since the beginning of the month. Some rain has fallen on every day as yet this month, and to the total depth of nearly 1½ inches. Of

this amount over half an inch has already come through the heavy soil, and about half an inch through the light soil percolation gauge. The winds, which have been rather high, have come almost exclusively from some point of the compass between south and west.—E. M., *Berkhamsted*.

## RETIREMENT OF MR. A. F. BARRON.

THE retirement of Mr. Barron from the Chiswick garden of the Royal Horticultural Society of London (after a service of considerably more than a quarter of a century) marks an epoch in its history as one of the centres of scientific horticulture in this country. For many years Mr. Barron has been a staunch and loyal official who has worked strenuously, even in the face of many difficulties and when environed in doubts and uncertainties of many kinds. Through all vicissitudes and unpleasantness Mr. Barron always acted firmly and wisely, and that he did his best for the society he served has been proved over and over again by the publications relating to the Chiswick garden in the society's journal. Placed in a most enervous position, the superintendent at Chiswick was brought into contact with all sorts and conditions of men, and he made many friends among gardeners generally. I may say fearlessly that no one alive to-day possesses such a full and accurate knowledge of hardy garden fruits and fruit trees as does the subject of this notice, and so far, even if no further, his retirement from Chiswick will be a loss not easily regained. The Apple and Pear and other hardy fruit reports of the society and "Vines and Vine Culture" are well-known works due to Mr. Barron's practical and literary ability, while the living and growing interest he has taken in the Gardeners' Orphan Fund entitles him to the gratitude not of gardeners only, but of all interested in the future of children left alone in the world. As an old pupil of Mr. Barron in the Chiswick garden before it was restricted in its area and scope as now, and as a friend since that time, I think that all gardeners will feel it a personal privilege and pleasure to wish the retiring superintendent God-speed and a happy and quiet period of comparative rest after so long, laborious and honourable a career.

My own notion of a testimonial would be a subscription, and if the funds were sufficient either to purchase a life annuity or to present him with what the poet craved, viz., "a small house and a large garden." The form of our respect is, however, immaterial; the main thing is to do something, and to do it quickly and thoroughly. That the Royal Horticultural Society of London will do their best for their oldest and most loyal official goes without saying, but Mr. Barron has really effected great and permanent services not only to gardeners, but also to the country at large, so far as fruit and vegetable culture is concerned. "Honour to whom honour is due."  
F. W. BURBIDGE, M.A.

**Royal Horticultural Society.**—The next meeting of the Royal Horticultural Society will be held on Tuesday, August 13, in the Drill Hall, James Street, Victoria Street, Westminster, at 3 o'clock. A paper by Mr. A. B. Freeman-Mitford on "Hardy Bamboos" will be read.

**Bog gardens.**—We should be grateful to any reader who would tell us of successful examples of these, with some account of their most beautiful inhabitants. Photographs of such gardens would also be most welcome.

**Names of plants.**—*W. Eastwood*.—A very fine form of *Odontoglossum luteo-purpureum*.—*B. Rogers*.—*Pentstemon barbatus*.—*A. E.*—1, *Euthera lamarekiana*; 2, *Euthera biennis*.—*S.*—*Dublin*.—1, *Sollya heterophylla*; 2, *Phytolacca decandra*.—*W.*—1, *Taxodium distichum*; 2, *Rhamnus alpinus*.—*A. Palmer*.—*Helianthus rigidus*.—*C. H. Fisher*.—*Veratrum nigrum*.—*R. C. Chayter*.—1, *Euthera Fraseri*; 2, *Euthera biennis*.

No. 1239. SATURDAY, August 17, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## FLOWER GARDEN.

### HARDY PLANT COLLECTING.

SOME weeks ago a correspondent, Mr. A. Bullen, suggested the employment of a collector of hardy plants in some rich and suitable locality on a co-operative principle, each subscriber to pay a certain sum towards the necessary expenses of collection, &c., and in return each to receive his proportionate share of the plants, bulbs, seeds, &c., secured. The suggestion is a good one, but perhaps a modification of the proposal may be made. There are now abroad in regions rich in hardy plants intelligent gentlemen, such as consuls and attachés, who would gladly employ native labour in the collection of the local flora if the costs of operations were guaranteed them. What I would suggest is the formation of a club or society, each member of which should guarantee to subscribe or to collect a certain sum annually to be expended in the collection and freighting of hardy plants, roots, and seeds. A secretary for correspondence (British and foreign) and other clerical work would be needed, and on this official would hinge in a great measure the success or failure of the enterprise. Still, I believe one or more amateur gardeners might be induced to take up this branch of the scheme. I believe that more could be done by utilising and interesting people now living in rich botanical localities all over the cooler latitudes or altitudes of the world than by merely sending a single handed collector to any one locality.

Now-a-days there are consuls, missionaries, agents and traders of intelligence nearly everywhere, and not a few of these do already collect specimens and seeds, &c., of plants and other natural history objects, though perhaps rarely in any systematic or organised manner. One of the first essentials would be to publish a short code of directions for distribution amongst residents abroad interested in the discovery and cultivation of new fruits, vegetables, and flowers. The plants desired should be indicated, and directions for their collection and transmission should also find a place. To some limited extent the machinery or organised communications of our British and foreign missions and other societies might be utilised.

As an example of the great results to be derived from resident collectors in their leisure one has only to point to the many lovely new bulbs, &c., introduced to Kew and other public and private gardens by Mr. E. H. Whittall, of Smyrna, and the late Dr. Jameson, of Quito.

The great Andean chain has yet to be explored by collectors interested in hardy or half-hardy vegetation. The same is in a great measure true of the highlands between Cashmere and Thibet. The Caucasus, the Balkan ranges, the Rocky Mountain passes, and the cold region of the southern pole no doubt contain many species and forms as yet unknown to our gardens. Amongst plants we should like to see alive there are many known in books and herbaria, but there are many more that have so far never been seen. Some of us would like such things as *Lathyrus magellanicus*, from the Straits of Magellan, or the curious *Caltha dionæfolia*, a dainty Buttercup, having leaves suggestive of Venus' Fly-trap. Then there is

the red *Dryas*, figured as *Cowania plicata* in Sweet's "Flower Garden" long ago, and now-a-days, when gigantic *Gunneras* are admired, we should like to cultivate the noble-habited *Gunnera peltata*, which grows on Robinson Crusoe's island of San Juan Fernandez. This remarkable plant is figured from a photograph in the narrative volumes of the great *Challenger* expedition, where we are told of its enormous leaves holding the rain water, as is done on a much smaller scale by *Saxifraga peltata*, a plant now commonly grown.

There is even yet much to be done in well-known places like Japan and Western America, and there is a rich field awaiting the hardy plant hunter in Siberia, Northern China, and Manchuria. But to send a collector well equipped to far distant places is a most expensive matter, and one full of risks and difficulties not readily foreseen. A better way would, as I believe, be to form a hardy plant club, to which club each member should subscribe £10 annually, and then try and interest collectors, consuls, missionaries, and trading agents who already live on the spot, so to speak, and who often welcome any pleasant and inexpensive way of spending their leisure time and discriminative ability. In any case, Mr. Bullen's idea is far too good a one to be entirely lost sight of, and I trust something practical may be the result.

F. W. B.

**Dog's-tooth Violets.**—In large spreading patches in the shrubbery, rock garden or woodland the quaint and beautiful flowers of this genus are very pleasing. Being for the most part cheap and of easy culture, they should be largely planted. So cheap indeed are some of the kinds, that they are well suited for carpeting the ground beneath such things as *Azalea mollis*, *Andromedas* and other such things. In these positions soil and situation are alike agreeable to them, and they flower freely year by year with no other attention than an annual mulching of short manure and leaf soil. Some of the choicer kinds would be equally well suited in these and similar places also, and possibly be safer. It is now a good time to plant these *Erythroniums*, and after so hot and dry a summer no further drying will be needed. Indeed, in any case prolonged dryness at the root is harmful to them, as they quickly suffer from dry rot, which is fatal. Where the patches have become crowded, lift, sort and replant at 3 inches deep in sandy loam with as little delay as possible.—E. J.

**Triteleias.**—Many object to these by reason of their odour, yet, apart from this, few dwarf bulbous plants are better adapted for massing for effect. Particularly effective is the white-flowered kind, and if given a good depth of sandy loam it will grow fully 9 inches high. Though upwards of twenty years ago, I well remember the remarkable vigour to which this kind attained in the Exotic Nurseries, Tooting. The plant was a favourite with the late Mr. Robert Parker, who made a feature of it by planting long, broad lines in one of the specimen beds. These beds (fully 150 feet long) had the two outer margins of this plant, other plants occupying the centre. In its season there were many thousands of blossoms of this white *Triteleia* of quite exceptional size and vigour, and thus seen they were very effective.—J.

**The Madonna Lily.**—It may interest some of your readers to know that my Madonna Lilies, which have been for several years very bad with the Lily disease, are this year quite free from it and in splendid foliage and bloom. I tried transplanting every year into new soil and every remedy I could hear of, without any result. The bulbs were so strong and healthy, I thought possibly the disease might be like that on the Potato, so I had them sprayed twice, once in April and again in May, with Strawsonite, half the strength used for Potatoes. It has been most

successful. Three plants purposely left unsprayed are quite bare of leaves and the flowers very poor, while all those sprayed are in vigorous health. I also found it most successful on *Lilium chalcedonicum*, which has not flowered for four years and is now very beautiful. I should say that my garden is a very old one and there are no imported bulbs in it.—E. PERRIN, *Knockdromin, Lusk, Co. Dublin, Ireland.*

**Anemone fulgens.**—Where this is grown in quantity it has no equal among dwarf early flowering plants for its brilliancy of colour. For this reason alone it is worth a place in every garden, planting it for the earliest display in a warm sheltered nook, or even providing frame shelter for it. In some soils, and especially those of a cold clayey nature, the tubers frequently deteriorate, and sometimes perish outright. In others, the tubers, while comparatively sound, fail to flower satisfactorily. Any that are thus inclined should now be lifted and dried thoroughly for two months at least. At the end of this time they may be replanted, using a good open and porous soil with sharp sand about the tubers. Experience will frequently dictate the best method to adopt in different localities. In some soils no doubt it will be advisable to lift the tubers each year, in others every second or third year. One of the chief drawbacks to retaining *Anemone fulgens* in the soil all the year round is the inclination to an early autumn growth. This in severe winters is cut completely off unless protected from the frost. Very few plants are more accommodating than this one, and it may not be generally known that the tubers of this scarlet Windflower will retain vitality for a whole year out of the soil, flowering fairly well at a reasonable time after planting. But success or failure in this is due entirely to the way in which the tubers are kept meanwhile.—E. J.

### PLANTS FROM JAPAN.

I AM importing some plants from Japan this autumn, and shall be very glad of any hints as to their treatment on arrival—Tree Paonies, Maples, double Cherries, Plums, and *Magnolia conspicua*.—M. P. F., *Northumberland.*

\* \* \* The treatment required will depend to a certain extent upon the size of the plants and the purpose for which they are needed, and also upon the condition in which they arrive, as if small or in doubtful health, they should be potted, whereas in the case of good healthy specimens they may be planted out at once. In dealing with the different plants mentioned, I will take them as they occur on the list.

Tree Paonies usually reach this country in good condition, as the stout, rather succulent nature of the plant enables it to stand a long journey better than many other subjects. The Japanese plants of the Tree Paony are almost invariably grafted on to one of the herbaceous section (some form of *Paeonia officinalis*, I think), and imported plants have often several stout roots as thick as one's finger and a couple of feet long. If it is intended to grow them in pots for the embellishment of the greenhouse, as is done by many, they must of course be potted. Though the roots may be shortened back somewhat without injury, yet even then it will be found necessary to use pots larger than those employed for many other things. They may of course be planted out on arrival, but if this is intended, a very good plan is to lay them in for a little while, just to see the state they are in, and thus form a guide for their planting. Whether needed for pots or the open ground, it will be necessary to look them over very carefully and remove every sign of a sucker, as great numbers are pushed up from the stock, more particularly if the scion has received a check. Even when established, constant attention in the removal of suckers must be paid them, otherwise during the growing season the scion will be quickly choked up with shoots produced by the underground portion of the stock. If when unpacked these Paonies are very

dry, a good plan is to soak them in water for two or three hours before anything else is done with them.

Maples, when unpacked, will often be found excessively dry, and a consignment I once received in this state, though the roots were soaked in water previous to potting, did not yield good results. This led me to try a further experiment, and having another lot to deal with, I tied them in a few bundles weighted with bricks and totally immersed them in a tank of water, where they remained about twelve hours. Then they were potted and placed in a cold house, exactly as the first lot had been, and they grew in a far more satisfactory manner, so from the result of my own practice I should say, most decidedly soak them previous to potting or planting out. Maples from Japan are invariably grafted, the stock employed being usually the typical *Acer palmatum*. Very frequently the stock is old and gnarled with very few fibrous roots, hence if it is intended to plant them out a good plan is to establish them in pots before doing so, as they then grow away without further check. The Japanese are very fond of grafting several kinds of Maple on to one stock, hence half a dozen or more distinct varieties are often to be met with on one plant. When in full leaf the effect is certainly curious, though, to my mind, much less pleasing than when each variety is kept distinct.

Double-flowered Cherries and Plums, if very dry, may be treated as recommended for the Maples, and can then be laid in in a sheltered place till they can be permanently planted, for the roots are generally so vigorous that in many cases they cannot well be potted, even if the plants are not in good health and it is desired to nurse them a bit. Should they die partially back, they, as a rule, quickly recover when the growing season comes round.

Magoolias had better be established in pots before they are permanently planted out, as if this is not done, they will often stand a long time before they start in a satisfactory manner.

One caution to be particularly observed is, that as the Japanese are remarkably fond of grafting, everything should be carefully examined previous to potting or planting, and as far as possible all embryo buds on the stock removed. For this same reason, even after they are established constant attention is absolutely necessary.—T.

#### ANDROSACE LANUGINOSA.

FROM an all-round point of view this charming alpine may be considered one of the most useful and beautiful of its race. Left alone it is rather straggling in its habit, but a good deal of this may be modified by regulating the shoots with a few tiny wooden pegs, thus forming it into more compact masses. But while its somewhat scattered style of growth may be taken as a defect on the one hand, it is on the other an undoubted advantage to the plant under cultivation. The majority of the species composing this beautiful genus of alpine have a caespitose habit of growth, and this, combined with their dense and woolly nature, tends to make them short-lived at best in our uneven climate. Exceedingly beautiful all of them undoubtedly are, though this is of little moment when all one's endeavours are at times exhausted to accommodate them. But the plant under notice is quite an exception, being easily grown and most readily propagated. The decumbent stems are about 1 foot long and furnished with silky white leaves, the stems terminated by rose-coloured heads of flowers with yellow centre. Given half a dozen plants, there should be no difficulty in quickly forming quite large patches of it on the rockery, preferably in positions where when in flower some of the stems could trail over a ledge of rock. A rock garden, however, is by no means essential, as the growth is generally more abundant when planted on level ground. In this position, however, unless the ground be carpeted with small stones for the stems to rest on, the entire beauty of the plant is destroyed by heavy rain. Even in the rock garden some such protection is

helpful in preserving the silky, silvery whiteness of its foliage and thus render it pleasing at all times.

The plant thrives well in sandy loam with either peat or leaf-soil added, while the addition of some burnt clay is also helpful. Propagation is best done by cuttings, employing the young points of the unflowered growths or, if quantity is required, the entire length of the flowering shoots may be utilised. Cut the latter into lengths 1 inch long, or, in other words, convert each two joints into a cutting, removing the lower pair of leaves in each case so as to permit of inserting them securely. Plant in very sandy soil or pure sand and kept moderately moist and not too close, the majority will root in a few weeks. Winter in the cutting pots and plant at a few inches apart in large patches in the rock garden or elsewhere in early spring in rather deep soil to ensure flowering the same year. There is also a white form—*A. lanuginosa oculata*, a very charming companion to the type and of equally easy culture. A pretty effect may be created by planting a mixture of the two. A few seeds may be had at times, but by far the quickest mode of increase is by cuttings, as suggested above. E. J.

#### FLOWER GARDEN NOTES.

HERBACEOUS PLANTS AND ANNUALS in judicious mixture are entering largely this year into the summer arrangements for the flower garden, and if the annuals continue to improve as in the last few years, it is safe to prophesy that in a very short time these will oust all those things whose cultivation necessitates a considerable amount of propagation in autumn and house room during the winter months. It must be remembered that all annuals chosen for such work must be thorough stayers; it is useless planting or sowing anything whose beauty is likely to be on the wane before the season is half over unless there is material at hand to refill the beds. Some of the prettiest beds I have seen this year were filled with scarlet *Lobelia* and *Gypsophila elegans*. The latter is a very beautiful annual, having the habit and good constitution of *G. paniculata*, the individual blooms being larger and slightly tinged with pink. The seed may be sown in the beds where the plants are to stand if this is practicable, and thinned out to the required distance or in prepared beds under cover and carefully transplanted. Owing to the very branching habit of the plant, thick planting is not advisable. The vivid colour of the comparatively new *Toadflax* (*Linaria reticulata*) makes it a capital plant with which to carpet beds already thinly planted with the white *Tobacco*, or it can be associated with a silvery foliated plant of similar height as some of the *Veronicas*, the rosy *Campion* or the variegated *Dactylis*. Lots of combinations of a similar nature can be effected with the aid of annuals and herbaceous plants to suit the taste of the planter, alike with dwarf, medium height, and tall plants, only it must be remembered, as hinted above, that the annuals must not be short-lived, and that if this objection is applicable to any herbaceous plants that are used, there must be a set-off in the way of ornamental foliage that is not likely to go to the bad until quite the end of the year. Colours, too, are furnished by annuals in variety not to be found among ordinary bedding plants. Beds of single and double *Gaillardias*, for instance, are just now quite unique, and they possess the merit of flowering well until quite the end of the season. For a glowing mass of colour, few things equal the *Calendulas*; they will flourish in any odd corner, only, as in the case of *Violas* and *Sweet Peas*, they require a little extra attention in the way of prompt removal of dead flowers in order to obtain a regular and well-sustained display.

*PHLOX SUFRUTICOSA*.—The suffruticosa section of *Phloxes* has been later than usual this year, possibly owing to the fact that they were late starting into growth, and they are now (August 9) only just getting past their best. I do not know if the majority of GARDEN readers who grow this

family—or rather this particular section of the family—have tried *Snowden*; if not, I should strongly advise them to do so, as it is one of the very best white flowers of midsummer. It throws a very fine, heavy spike of pure white flowers, individual pips being large and firm. We have to thank the raisers of new *Phloxes* for those characteristics in size and firmness of pip. There is a wonderful difference in this respect between these new varieties and the flimsy white and rose-coloured shades of twenty-five years ago. A good point in the *Phloxes*, and, indeed, in the majority of the big families of herbaceous plants, is the ease with which they can be increased either by division or cuttings. If the cuttings are not taken until rather late in the year they will strike the more readily if put in pots.

TUFTED PANSIES.—In answer to the query on page 84, I have never found any difference in the cutting-producing properties between plants acquired from cuttings or by division; indeed, I have at the present moment two beds of *Annie King* and *Lilias* that were made up last autumn in about equal parts of cuttings and old split-up stuff, and there is no perceptible difference in the growth. I have always found that the cutting plants flower earlier in spring. In the excellent article on the propagation of tufted Pansies, the writer, I think, somewhat misses the point in my notes. I am quite ready to concede the fact that any amount of cuttings can be obtained from plants that were put out in specially prepared beds, and that through a dry time were carefully attended to every day in the matter of water, but I was writing of *Violas* in the flower garden that were planted last autumn in ordinary garden soil, and from that time have had to shift entirely for themselves, receiving no extra attention. Under such circumstances there was very little growth on most sorts, especially of the *Kintore* type at the time we generally take cuttings (towards the end of July), but the grand rains have set up the plants wonderfully and growth is now abundant.

PROPAGATING.—One outcome of the increased use of herbaceous and annual subjects is the yearly lessening of labour in the matter of the autumn propagation of tender plants, and they are now in many places so thinly represented, that a very small stock from which a few more can be taken in early spring is all that is required, the propagator naturally paying special attention to any particular colour which has been favourably received and which is likely to be wanted in increased numbers another year. There are also one or two things demanding special attention which may be noted. The silvery *Centaurea* is not as a rule raised from seed, but it sometimes happens the batch or part of the batch of seedlings has something special about it; they plants may be of a clearer white, the foliage may be finer or more deeply serrated, and so it is deemed advisable to perpetuate the stock. Cuttings of this *Centaurea* should be slipped off with a heel, no more trimming being done than is absolutely necessary, and then inserted singly in a compost of three parts leaf soil and one of sand in 3-inch pots. They only require just enough water through the winter months to prevent the foliage from withering. If there is any evidence of the presence of the leaf-boring maggot on *Marguerites* only the very tips of the shoots should be taken; it is better to put in a cutting only half an inch in length than to include leaves that are furnished with the small excrescences that indicate the presence of the maggot, or, at any rate, the maggot in embryo. Scented flowers, or rather flowers with scented foliage, do not strike very readily if the growth is hard, and if only a small stock is required, it is as well to lift a few old plants which, if put into heat in spring, will yield an abundance of cuttings; this will apply to *Aloysias* and to all the scented *Pelargoniums*. Writing of lifting reminds one that there are certain inmates of the flower garden—as *Paris Daisies* in variety and the *Margarita* section of *Carnations*—that if taken from the open ground and potted will give a nice display right through the autumn months and

nearly up to Christmas. If such lifting is contemplated the plants should be partially cut round with the spade towards the end of the present month and the operation completed in the course of a fortnight. They will be in good trim for removal about the third week in September, and if the lifting and potting are carefully performed and the plants are shaded from the sun for a week or two, there will not be the slightest check to flower or foliage.

E. BURRELL.

Claremont.

### CARNATIONS FROM SEED.

THE Carnation is a peculiarly difficult plant to manage in many places, the proof being that so many people absolutely fail with it. The reason is on many soils the necessity of annual propagation and planting in a timely way, and as many growers do not exactly know the need of this, or from pressure of work do not do it, failure is pretty constant. In certain soils, especially in those by the seashore, the plant is less difficult to manage, and often it does admirably with a little attention, but we are speaking generally.

Another reason is perhaps that the Carnation is naturally a biennial plant, *i.e.*, sowing itself one year and blooming and dying the next, so that it cannot be said to be a true perennial. No doubt these difficulties can be got over by people who really give themselves to the task, but even with these there are occasionally years like the past, in which, owing to the heavy cold rains of autumn, the plants do not root well and the layers come almost to nothing.

We wish to point out that a very good way to make up for difficulties of this kind is to grow the Carnation more commonly from seed sown every spring in a cool frame in March or April, the seedlings being pricked out in summer. Such seedling plants will be much more vigorous generally than the layered ones; they pass the winter better, flower more freely and give more lasting bloom. The drawback is that we get what chance gives us instead of the exact reproductions of the plants from layers, but if we take care to get seedlings of a good strain, we may find in them plants as handsome as any named kinds, though there may be a percentage of single and rather poor flowers. Seedlings may be put out, too, in beds not so carefully prepared as for the named layered plants, but in rough borders, bits of spare ground in the kitchen garden or nursery, half-covered ground in shrubberies, and in such places they will do well.

It is probable that in the future our seedsmen may do a little more to help the growers in this way by fixing the different colours; for instance, we ought to be able to buy seeds of reds and yellows, and so on. But as things are, mixed seed of good quality often gives us handsome plants, and there is the additional interest of perhaps finding among our seedlings varieties of beautiful character or novel colour, which indeed frequently happens; and there is the further interest to growers of saving seed from choice plants of beautiful or striking colour, or bold habit, or likely to be parents of good kinds. We find the best results from saving our own seed. Choose the first flowers of the finest varieties, and a much greater number of fine-flowered seedlings will be obtained. A large lot raised from seed produced by chance, although the varieties that gave it were all first-class, surprised us with their poor quality and large percentage of single or otherwise worthless flowers. The following year seed was only saved from selected hand-fertilised flowers, and these same varieties gave the finest batch of seedlings we ever had, nearly every one as good as the named parents. The reason is that the best and most double varieties will not produce seed if left to chance or insect intervention, the flowers' abilities in this respect being apparently in proportion to their quality, inferior flowers giving seed in abundance, of which the progeny will most likely be worse than the parent. We are convinced, however, that by saving one's own seed and raising a batch of plants each year, we can have Carnations in our gardens equal in quality

of bloom to the named sorts and in greater quantity, as no Carnation plant flowers so strongly as the seedling; and if we always treat it according to its biennial character we are less at the mercy of the season. Seedling plants that have a summer for growth become so established that no winter can harm them, and they acquire a vigour that expends itself in a fine display of flowers, whatever the summer may be.—*Field.*

— I was in a Reigate garden the other day and saw in bloom part produce of the plants raised from a packet of seed sent out by the Carnation and Picotee Society to its members. I do not know whether the produce of such seed is of better or worse quality than is obtained from the trade or other home sources, but all in this case was evidently of home saving. The total was originally about 100 plants. Of that number some twenty or so had proved to be single, and a few others of a semi-double nature, none being retained. Then when all were in full bloom some more either showed a loose, tree habit quite unsuitable for border culture, and some others had huge pod-splitting flowers that were ungainly and worthless. All these were pulled out also. There was left a very admirable lot of seedlings, and probably of at least twenty or more varieties or of diverse shades of colour or markings—white, flesh, yellow, pink, rose, scarlet, crimson, and numerous fancies, Picotees, &c., not one but was as well worth a name as are myriads of those we find in catalogues as border Carnations. All the best have been layered, and there will be hundreds of good plants to bloom next year. There is a fine result in Carnations from a mere packet of seed. Why should not seed be sown every year in gardens as well as increasing the best by layering? Really it does now seem absurd to be naming and certifying varieties when we can get such beautiful things from seed strains. Those who raise a few scores every year from seed have, apart from enjoying the beauty of the flowers, always the pleasant excitement of wondering what sorts of blooms are about to unfold.—A. D.

**Begonia Worthiana.**—My short note in praise of the above (p. 38) has done good service, as it has called attention to other and, as Mr. Bedford informs us, superior varieties. I am ignorant as to the value of the varieties he mentions. I have tried several other kinds of *Begonias*, but none have succeeded like the one named. I will certainly give those that Mr. Bedford advises a trial if I can get them.—G. WYTHES.

**Venidium calendulaceum.**—This fine and showy annual was a few years since announced as a novelty at 2s. 6d. a packet. I recently saw a large plant of it on the rockwork in Mr. Robert Sydenham's garden at Birmingham, where it was highly effective, blooming freely, the colour bright clear yellow, with a dark disc, the flowers lasting a good time. It is in the bright sunshine that this charming annual is seen to the best advantage; it blooms with wonderful freedom and it is excellent for cutting from, though its blossoms will partly close in a dull light, and in cloudy, dull weather while on the plant. I find it does best in a warm sunny spot. It is also continuous in bloom, provided the seed-pods are not permitted to form. It is by no means so widely known and grown as its merits deserve.—R. D.

**Hardiness of sweet-scented Verbena.**—“E. J.” will be more surprised than ever to hear that the scented *Verbena* has proved itself hardy not only in Middlesex, but in Notts also. A large plant which grew against a wall at Barnby Manor, Newark, for a good many years without being injured by frost—although crippled by the 40° registered in those gardens last February—was not destroyed. True, a piece of garden matting is tacked over it every autumn, but nothing in the shape of coal ashes is placed over the roots. From the appearance of the wood last spring the gardener feared the plant had succumbed, but with the return of warmer days growth started freely from the base, as in the case of

“E. J.’s” plant. Doubtless many of our most beautiful and sweetest scented plants now supposed to be very tender would stand keen frost with impunity, especially in sheltered situations and with a slight temporary protection. When such subjects are growing against walls which have not good copings, it is a good plan to fix a piece or two of slate in a slanting position at the base of the plant to prevent drip from ruining the collar.—C. H. N.

**Gypsophila paniculata and its uses.**—This hardy perennial is now pretty well known. It is, indeed, a boon to the florist and to those who wish to secure lightness and elegance in the decoration of the dinner table or epergne. At a local show lately it was used with good effect in both the first and second prize table decorations, being associated in one instance with yellow and white Iceland Poppies and Maiden-hair Fern, and in another with white and yellow Marguerites. Grown amongst flowering and fine-foliaged plants in pleasure-ground borders it is very effective, and it is so hardy as to survive the sharpest winter. With me it does not flower until July even on a sunny border, and as it would be most useful in June, I intend planting roots this autumn in a spare pit facing south in order to induce it to bloom at that date.—J. C.

### DISEASE IN LILIUM CANDIDUM.

“S. W. F.,” who summarises at p. 54 on the causes of the disease in the above-named *Lilium*, also adds to the possible or probable list of causes “that the disease is mostly, if not entirely, confined to imported bulbs.” I can, however, show that this theory is wrong. It is now about ten years since this disease first appeared. About this same time calling on a gardener at Sunbury-on-Thames I noticed some fine clumps of this *Lily* in a sad plight. The gardener knowing, asked my opinion as to the cause of the failure. I told him then what I still believe to be as likely as any reason which has been put forth, that I believed that the disease had been imported originally with the bulbs from France. Having thus got a footing in our gardens, it was ever present, merely waiting for certain atmospheric conditions most suited for its development. The clumps above alluded to were old ones, had occupied their then position for several years, and had flowered splendidly each year, excepting that referred to. Now in this case nothing whatever had been done to the bulbs; they were just where they had been for years past and had done so well, and their flowering annually was regarded as a certainty. The disappointment, therefore, at so complete a failure was great. Ample evidence was also before us at the time that the previous year's growth was good, and that such growth was well matured, as the flowering stems were then about 4 feet high. Here, then, is an instance of old-established clumps hitherto a complete success being quite wrecked by the disease. Nor is this an isolated case, for I have since seen many instances in cottage gardens where this *Lily* had been among the occupants for many years, and where “imported” bulbs were never dreamt of. But the fact of their being old-established does not carry with it immunity from disease, for who shall gainsay that the ever-present germs of this or any other disease shall not be carried miles and miles away, hither and thither in all directions? And it is just possible that dwellers in low-lying and moisture-laden districts will feel its attacks earlier and perhaps more keenly than those in higher and drier localities. In a season like the present one the disease is much less severe, and in this part of Middlesex instances of it are only few in number. But the fact that there is disease, as pointed out by “S. W. F.,” in so tropical a summer entirely disproves the contention that cold, rain, hail, and the like are the origin of the disease, for in this district at least we have been quite free from such weather till the Madonna *Lily* was nearly out of flower. The experience of “S. W. F.” respecting this *Lily* in cottagers' gardens differs from my

own, as I have stated above. Yet in the main "S. W. F.'s" experience of imported bulbs goes a long way in supporting my own views.

I would, however, like to tempt "S. W. F." into trying my baking process with these imported diseased bulbs. It has proved efficacious enough in some instances, and in those that fail, either wholly or in part, I incline to the opinion that the baking or drying is insufficient or incomplete. There is yet time, and time to do it well, and that the experiment may be trustworthy, I would suggest leaving a few in the soil just as they are. But lift the bulk, divest them of stem and leaf, which should always be burnt, and place the sound bulbs on a shelf near the glass in the greenhouse, where they may, near an open ventilator, obtain every possible drying influence. Let there be no shading on the glass whatever, and by turning the bulbs every few days, expose all sides alike. Give them this course of treatment for about two months, after which they may be planted, but not too deeply covered. Do not expect any radical growth this autumn, and be not surprised if some remain dormant during next year; indeed, this is most likely with the more weakened bulbs. I have now some bulbs, a portion of a badly diseased stock of 1894, which I purposely obtained for experiment, which after the drying never put forth any growth till now, though they emitted plenty of roots. These bulbs are now pushing forth their autumn leaves, and if undisturbed will possibly flower another year.

I have not as yet tried syringing the plants with the Bordeaux mixture, but I see no reason why it may not be tried early in the season, more as a preventive measure. Indeed, I am of opinion than any remedy must be rather a preventive one by reason of the very rapid spread of the disease when once it puts in an appearance. It is a singular fact, too, that this particular disease confines itself to those Lilies whose leaves are somewhat soft in texture.

H. H. M.

#### NOTES FROM MYDDLETON HOUSE.

HARDY plants of all kinds form a delightful feature in the beautiful garden of Mr. Bowles, at Myddleton House, Herts, and though my visit to this garden did not take place until the beginning of August, I was amply rewarded in finding many interesting plants still in bloom in spite of the unfavourable season. In front of the house is a gently undulating lawn, on which among many other handsome trees is a very fine specimen of the deciduous Cypress (*Taxodium distichum*), not less than 60 feet in height. An extensive pond is fringed with Irises and other suitable plants, while on the water float handsome Nymphaeas of various kinds.

Many bold and effective plants adorn the various borders, and among those still in bloom I noticed *Pentstemon killosoni*, with large purple flowers, and also bold masses of the handsome Cotton Thistle (*Onopordon acanthium*). *Campanula bononiensis* alba is represented by a specimen quite 3½ feet or 4 feet high; the white flowers are small individually, being not much more than 1 inch in length, but as they are disposed in a very long raceme and in large numbers, the plant is very striking. Most effective, too, are the variegated Comfrey and the bold *Oreocome Candollei*, with its large compound Fennel-like leaves and umbels of white flowers 5 feet high. In another border *Achillea decolorans* bears its corymbs of pale yellow flowers 3 feet from the ground, and *Cichorium intybus* is conspicuous by its deep blue blossoms. *Antholyza paniculata*, *Abutilon vexillarium*, and *Lythrum virgatum alatum* are also in bloom.

Not the least interesting feature is the rock garden, which, though on a small scale, contains, nevertheless, a fine collection of suitable plants. Among those still blooming I particularly noticed the following: *Linaria repens alba*, with white flowers, appearing from a distance more like Lily of the Valley than the flowers of a Toadflax, *Linaria reticulata*, *L. antherinifolia* (purple, with

yellow throat), *Francoa sonchifolia* (white), *Teucrium purpureum*, *Tunica Saxifraga*, *Aira cuspitosa*, *A. vivipara*, *Cerastium grandiflorum*, and the pale blue *Borago laxiflora*. The pretty red and yellow flowers of the Canadian *Corydalis glauca* are to be seen in great profusion, and are borne well above the bipinnate glaucous foliage of this interesting plant, which unfortunately is an annual, but seeds itself freely.

Very sweet is the perfume emitted from the foliage of *Micromeria Douglasi*, which is grown more for the sake of its delicate scent than its inconspicuous flowers.

The white Marsh Marigold (*Caltha leptosepala*) and the sweet-scented white Orchid, *Spiranthes aestivalis*, are growing from a bog bed, carpeted with *Pratia angulata* and other suitable plants.

The garden of course contains many treasures which are now out of bloom, and therefore omitted from this short notice.

Elmside, Exeter.

F. W. MEYER.

**Tufted Pansies.**—I recently noted a few of the most useful sorts for masses from a collection of close upon a hundred. The following may be expected to succeed in almost any soil with ordinary attention: Ardwell Gem, yellow; Wm. Neil, pale rose; Blue Gown, a most refined self colour; Sweet Lavender, soft lilac; Sylvia, pale primrose; Countess of Hopetoun, white; and Blue Cloud, white, distinctly edged blue.—H.

**Tufted Pansy Border Witch.**—This sort is among the most beautiful of all. The colour is pale lavender-blue, delicately shaded with a lighter tint. Mr. Baxter, Woking, has it in capital form, where its striking colour is very telling, and one may pick it out even when surrounded by dozens of other varieties. The sort is recommended for the flower garden, having an excellent habit of growth.—H.

**Gaillardias** are now in great beauty, having apparently been greatly benefited by the recent bountiful rains. Within the past three weeks a considerable amount of fresh growth has been made, and a great show of flower-buds is the result. With good open weather these will furnish a profusion of their blossoms for weeks to come. It is a good time to sow seeds of these for planting in October next. Such as these will form good plants for next year's flowering, and be far in advance of those raised in spring in slight warmth.

**Crown Imperials** (*Fritillaria imperialis*).—These early-flowering bulbous plants may where large clumps exist be lifted and replanted at any time during the present month. It is not advisable to leave them beyond this time, as their naturally early flowering is responsible also for a more early rooting than is usual with some bulbs. They may, however, be procured from dealers in hardy bulbs in a dry state after this time. Early in the year these plants are very useful in the open border on account of their distinct and effective character. Especially worthy of every attention are the gold and silver-leaved forms of these plants. Apart from their foliage effects, the plant is handsome and worthy of good culture. Especially is this true of the yellow-flowered kinds. Apart from the yellow and sulphur-flowered kinds, there are others of bronzy crimson and of varying shades of red, the variety *rubra maxima* having immense red blossoms of a size fully equal to the largest Tulip. Any fairly good moderately rich soil suits them well, planting the bulbs 6 inches deep.—H. H.

**Asciopias tuberosa.**—This is not only one of the most distinct of hardy herbaceous plants, but it is also one of the showiest, and most worthy of extended cultivation; yet, notwithstanding its distinctive colour, it is seen but rarely in our gardens. While rarely seen in anything like good condition on soils that are cold and wet in winter, it may be grown quite easily on light warm soils. Where such do not exist it would be very easy to prepare a barrowful or so of suitable soil, say of

peat, leaf soil and sharp sand in equal parts. This, added to the ordinary garden soil, or even discarding the latter altogether and preparing a bed of the soil named, with a few inches of drainage, would be sufficient to secure success. The brilliant and compact umbels of orange-coloured blossoms are produced terminally on stems nearly 2 feet high, and at any time of the year the peculiar shade of colour is by no means plentiful. In those gardens where special accommodation is given to American shrubs of a peat-loving nature this plant might also be included. Once planted in suitable soil it should remain undisturbed for several years. The plant may be readily raised from seed, which is easily obtained. In this way flowering plants may be secured in about two seasons from the sowing of the seed.—E. J.

**Galtonia candicans.**—Among hardy bulbous plants the above is just now one of the most conspicuous in flower. It is an excellent plant in many ways, and admirably adapted for the flower garden, the herbaceous border, or in bold, telling groups in the conservatory. In each and all of these it is capable of producing quite a unique effect. Perfectly hardy and of robust constitution, large bulbs will frequently produce from three to five of the giant spikes, each carrying perhaps a score or more of pure white, drooping, funnel-shaped flowers. Now that it may be obtained cheaply it should be freely planted in the wild garden and woodland. Seeds are produced abundantly, the seedlings making rapid headway and flowering in the second or third year when they are grown quickly from the earliest stages. Open spots in the foreground of shrubberies may with good results be filled with this, planting it always freely in groups.

#### NOTES FROM OAKWOOD.

ALTHOUGH the heat and drought of early summer much affected the growth of the auratum Lilies in the high grounds of Oakwood, those in moister, less exposed positions show no diminution in vigour. The flower-stems are very stout, some running up to a height of 9 feet, carrying twenty expanded flowers of fine quality, with many buds to open. Fasciated stems carry a much greater number, but not nearly so large. One good feature of this Lily is the succession of bloom that can be had by planting a sufficient quantity of bulbs, the flowering season extending over a period of six weeks or more. *L. canadense* is a pretty species with slender stems and bright blooms, quite a gem. It is flowering well at Oakwood. *L. superbum* is quite at home, throwing up tall, stout flower-stems in moist places among evergreens, which show up the richly tinted blooms to great advantage. It is also doing well, though not attaining such dimensions on the hillside. *Gentiana septemfida* grows luxuriantly, forming broad masses of healthy foliage with abundant heads of bloom. It resembles its early-blooming relative, *G. acaulis*, although the colour of the flowers is not so rich and they are produced in crowded heads. *Montbretia Pottsi*, forming a dense mass of foliage several yards through and crowded with flower-stems, was very pretty, while a thicket of the bright flowered *Polygonum sphaerostachyum* was very attractive. *Indigofera dosua* is a cheerful-looking species, the flower being of a bright attractive shade of pink. Of the Sea Hollies, *giganteum* is perhaps the most striking on account of the silvery grey colour of the foliage. *Sedum pulchellum* is one of the most distinct of a large family, being of robust habit and flowering abundantly. *Rhexia virginica*, when seen in a really thriving condition, is one of the most distinct and loveliest of hardy flowers. The flowers, though small, are by reason of their bright colour quite showy, so that a clump when in full bloom is very effective. It has evidently become quite at home at Oakwood, and is decidedly one of the prettiest things there just now. It evidently enjoys moisture at the roots, but I should say it is not likely to last long in close, retentive soil.

J. C. B.

**AGAVE CONSIDERANTI.**

This, also known as *Agave Victoriae Reginae*, under which name it was awarded a first class certificate by the Royal Horticultural Society on October 6, 1875, is certainly the gem of the family. At first sight its habit suggests the filifera group, but the filaments here are rarely produced, while the plant is more noble and

was introduced from the cooler parts of Texas in 1872 by M. V. Considerant. A plant was purchased by the late Mr. Peacock, of Sudbury House, Hammersmith, who at that time had a fine collection of succulents, and was exhibited by him under the name of *A. Victoriae Reginae*, which name undoubtedly ought to be put on one side, and the proper name, *A. Consideranti*,

crimson shade and of true Cactus form. The only fault is that the flower is too large; this, however, may be remedied by not being too kind in the preparation of the soil and by allowing every bud on the plant to develop.—H.

**Cactus Dahlia Robert Cannell.**—Magenta shades in flowers are not popular, but in the case of the colour of this variety it is relieved by a light shade near the edges of each floret. This produces a rich colouring. It is of medium size, true form, not too tall in growth, and withal handsome.—H.

**Cactus Dahlia Delicata.**—This is a charming variety of true form, which is light and graceful. The shade is soft pink, fading to blush at the points of the florets. If one may find a fault it is that, like too many of the Cactus Dahlias, it does not throw its blooms well above the foliage.—H.

**Clematis Henryi.**—The large blooms of this white variety are especially showy and it is far the best of its colour. Its flowers are about 8 inches in diameter and freely produced. This Clematis belongs to the lanuginosa type, and therefore produces its blossoms on the young newly-made growth. As a climber trained against a wall it is very handsome.—H.

**Clematis Princess of Wales.**—This is a fine variety. The colour is bright lavender and its blooms are each about 6 inches across. I saw a specimen in flower a short time back which had been planted against a house four years, and it had upwards of a hundred blooms fully out at one time. The showy character of such a plant may easily be realised.—H.

**ORCHIDS.**

**SEASONABLE NOTES ON ORCHIDS.**

THE stormy weather of late has necessitated frequent application of fire heat in the warm houses. The temperature would not fall low enough at night to do any harm, but by keeping the pipes moderately warm, a good chink of air can be left on at top and bottom, and this is just now of especial advantage, as many plants are finishing up their growth and must be kept dormant afterwards. A free circulation of air is the best possible means of preventing the plants starting away, and though fire heat keeps the temperature up, so that other plants that may be growing are not checked, less watering and damping have also been needed, and advantage may be taken of the lull of work to give the plants in all departments a thorough cleaning. This cannot be done too often, for if only a few insects are found, the plants are better for having the dust and dirt that will accumulate upon them sponged away, this greatly adding to their appearance and benefiting their growth. Red spider frequently attacks the foliage of *Dendrobiums* at this season, and in cleaning a careful watch must be kept for this. The small white scale, too, is frequently in evidence upon the leaves and bulbs of *Cymbidiums*, such as *Lowianum* or *giganteum*, *Cattleyas*, and many others, and cleaning would have to be done very often and carefully, too, if these are to be thoroughly destroyed. With the latter, the scaly bases of the pseudo-bulbs and the rhizomes should come in for careful attention, pulling the sheaths right off if the insects cannot otherwise be removed. Many *Cattleyas* at this season, while not requiring repotting, will be better for a little surfacing with good sound peat and Moss. *C. Leopoldi* and others of the guttata section are emitting roots freely, and these pushing through the new compost strengthen the plants materially. Plants of *Cypripedium insigne* grown in rather a warm house are pushing up the flower spikes freely. Where other plants are growing in a different temperature, these latter will keep up the display when the former are past, but if all have been growing in the same house, a few of the plants should be placed in cooler quarters

*Agave Consideranti (Victoriae Reginae) in the Marquis de Fronteira's garden at S. Domingos de Benifca, near Lisbon. From a photograph by J. Guerra.*

massive in character. The leaves are terminated by a strong, black, wavy spine having a few small secondary spines on two of the three edges which the leaf has at its point. The margins of the leaves are entire and edged with white, conspicuous white markings or lines showing the imprint of the previous leaves. It

used. The Marquis de Fronteira, who kindly sent us the photo from which the illustration was prepared, says that the flower-stalk grew at the rate of 8 inches in the 24 hours.

**Cactus Dahlia Matchless.**—The name for this is well chosen. It is almost black in its dense

for the same reason. Deciduous *Calanthes* have now filled their pots with roots and will be benefited by a little weak soot water at the roots. The growth, too, must be inured to more sunlight and air, as soft, flabby foliage soon falls, and the longer this is kept on the better the spikes will be. This exposure must, however, be brought about gradually, as no Orchids are more easily injured by sudden changes. They must still be kept in the warmest house, and no diminution of the water supply will yet be needed. *Laelia superbiana* is just now producing its spikes from the apex of the new growth, though it will be months before the flowers open. It is, however, a capital time to set about improving struggling plants by notching half way through the rhizome just beyond where the growth is required. I have always found the growths come more seasonable when this is done now than if left until spring, possibly because of the eyes having plenty of time to plump up during the winter months, and therefore being ready with the increased heat and light in spring to break at once into growth. The most promising looking eyes should be chosen, those that look round and full, as these are the most likely to break strongly and well.

Several of the forms of *Laelia elegans* are now very beautiful, and contribute largely to the attraction of the flowering house. Interspersed with these autumn-flowering *Cattleyas* and *Laelias* the feathery spikes of the old and pretty *Oncidium flexuosum* have a light and pretty effect, while the sweetly-scented *Maxillaria Harrisoniae* has still a few flowers left. *Odontoglossum vexillarium* is again on the move, and will soon require attention at the root. The best of the material should be used for this lovely Orchid, and before repotting or surfacing see that the plants are entirely free from insects. The cool species are enjoying the present stormy weather, those in frames especially benefiting by the warm showers, while the cool house can be left almost wide open day and night. *O. Edwardi* is throwing up strong spikes, and the plants need abundance of water at the root. A full supply is also required by *Anguloas*, *Lycastes*, *Oncidium tigrinum* and others in full growth, but any that are finished must be carefully watered until the spikes are showing. As soon as these are seen it is safest to either elevate the plants upon inverted pots in saucers or to use the pans now made to answer the same purpose, viz., to keep the slugs and other insects away, care being taken to thoroughly isolate the plants. If one leaf is touching another plant the insects will probably find the spikes out by instinct, and the mischief they do is surprising. Carefully note the smaller habited kinds of *Oncidium*, as *O. longipes*, *O. cucullatum* or *Odontoglossum Cervantesi*, and see that the little bulbs are firmly fixed and also have room to swell. A little attention now makes a wonderful difference to them, placing a bit of Moss or peat here or a small stake there as seems to be necessary. While encouraging the *Sphagnum Moss* to grow freely about them, it is very unwise to let it creep too high up the pseudo-bulbs of these small-growing species, and a little of it should be pulled out or cut off as soon as it is seen to be encroaching. As the days shorten the shading will be diminished and every effort made to ripen up the growth in all the houses. The temperature of the warmest house may stand at about 65° by night, rising almost to 100° on bright afternoons at closing time, but 75° is ample by fire-heat. The *Cattleya* house will be best kept rather steadier, 55° being ample at night for the majority of the species, while any requiring more heat may be

placed in the East India house for a time. The cool house, as mentioned above, is left open at night, but during hot days it will still need to be shaded heavily, damping all the stages, floors and dry places several times through the day.

R.

#### BLETIAS.

If we except one species, *B. hyacinthina*, this old genus of terrestrial Orchids is hardly ever seen, yet several of the species are very useful and decorative plants. They are of the easiest culture, and thrive either in a cool Orchid house, an ordinary plant house, or pit. They are widely distributed over China and Japan, some species also coming from America. The best way to grow them is in pots or pans in a compost consisting of good fibrous loam and chopped *Sphagnum Moss*, to which a good proportion of leaf-mould and plenty of finely broken crocks should be added. They may be potted as soon as, or rather before, they commence to grow, draining the pots well and keeping the top of the pseudo-bulbs a little below the rim of the pot, and not raised, as in potting epiphytal Orchids. If potted before growth commences the plants may be plunged in ashes over the rim of the pot, which will keep them in the right state for moisture without watering, provided the soil at potting time was not too dry. When the growth appears, a little water must be given, this being increased as the roots begin to run, allowing a free supply when in rapid growth. Abundance of air must be given while growing, and the shoots frequently syringed in order to keep the foliage free of insects. Plants newly potted will require nothing in the way of manurial stimulants the first year, but after they are well established in the pots a little well-diluted liquid made from cow manure and soot may be used at intervals of about a fortnight. This will increase the vigour of the plants and the flowers will be more highly coloured. They will bloom at different times, according to the time they are started and the rapidity with which they are grown, and as soon as the flowers are past the plants may be stood out of doors in a sheltered, sunny position. At first they may have the full advantage of the heaviest rains, but as the foliage begins to ripen they must be protected from these, but exposed to light showers. By the end of August they will need to be taken inside again, and very little water given during the time they are resting, again increasing the supply as the new growths start. Formerly several other Orchids were called *Bletia*, as, for instance, *Brassavola acaulis* and *Digbyana*, *Laelia Perrini*, and several others.

*B. HYACINTHINA* is a free-growing and handsome species nearly or quite hardy in a sheltered position. The flowers, produced on scapes a foot and upwards in length, are bright rosy purple in ground colour. The lip is white with crimson-purple lines and spots. This is extremely pretty arranged with *Odontoglossums*, the tall scapes having a light, yet telling effect. This was introduced from China as far back as 1802, while a light-coloured form of the type with a violet lip was introduced from Japan in 1843 under the name of *B. Gebina*.

*B. PATULA*, being a native of the West Indies, requires more heat than the other kinds and a drier atmosphere. This may be well grown in a house such as suits the Mexican section of *Laelia*, and thrives in the same quality of compost as the other kinds named. Like them it requires a good rest, and during this period may be kept cooler. The flowers are lilac-rose on the sepals, petals and front of the lip, the ridges on the latter being wider. Introduced in 1830.

*B. SHEPHERDI* is the largest and strongest-growing in the genus, producing long, branching scapes of deep purple flowers at various times of the year, usually in late winter or early spring. The pseudo-bulbs of this kind are apt to decay if too deeply buried, and some growers prefer to keep these just above ground. The growth is, however, better if they are kept below, and if not kept too cool and moist they are safe enough with ordinary care. This was introduced from Jamaica in 1825.

*B. SHERRATTIANA* is another very pretty kind which bears long, erect spikes of pretty soft rose-coloured flowers. The lip is deeper in colour than the rest of the flower, being deep purple, with golden yellow lines running through the middle lobe. A native of New Grenada, whence it was introduced in 1867.

*B. VERECUNDA* is interesting as being the oldest Orchid now in cultivation, having been grown in England ever 150 years ago. It is hardly worth growing as an ornamental plant, the flowers being small and dull in colour. It is also a native of the West Indies, and therefore requires a warm house, where it flowers during the summer and autumn months. R.

**Saccolabium celeste.**—This beautiful little species is now in bloom, the pretty white flowers tipped with sky-blue being quite distinct from those of any other Orchid. This is a native of Siam and first flowered with Sir Trevor Lawrence. It should be grown in the warmest house, not far from the roof glass, in wooden baskets filled with *Sphagnum*. It must have a bright clear light all the year round and only needs to be shaded from the brightest sunshine. During winter the plants must never be dust-dry, though requiring much less water than when in full growth, and the temperature must not be allowed to fall below 60° at any time.

**Oncidium luridum.**—This belongs to the section of the genus without any pseudo-bulbs, and is an interesting and pretty species. The leaves are light green, covered with very small spots, and the flowers are produced upon erect racemes about 2 feet in length. These are greenish yellow in ground colour, sometimes blotched with chocolate-brown, while other varieties are spotted with bright red. It is best grown in pots, with two-thirds of *Sphagnum Moss* to one of peat, and should never be dried at the root. Being a native of Jamaica, it thrives well in the *Cattleya* house.

**Epidendrum fragrans.**—As the specific name implies, the blossoms of this Orchid are very fragrant, a single spike of flower perfuming a house. It is very much like *E. cochleatum* in growth and also in the shape of the flowers, but the latter is rather the stronger grower of the two. The pseudo-bulbs of *E. fragrans* are not usually swollen so much in the middle as those of *E. cochleatum*. The blossoms occur in small racemes from the top of the newly-formed pseudo-bulbs, and are creamy white in ground colour with a few purple streaks about the lip, which is uppermost, giving the flowers the appearance of being upside down. It thrives well in the *Cattleya* house, requiring a moderate supply of water the whole year round, less of course being necessary during the winter than when the plants are growing. It is a native of the West Indies, very free flowering, and the blossoms last well in good condition.

**Grammatophyllum Ellisi.**—This beautiful plant is a native of Madagascar, and is named after its introducer, the Rev. W. Ellis. It is the most popular in the genus, and a most desirable Orchid on account of its freedom of flowering and its bright, attractive appearance. The pseudo-bulbs are from 10 inches to a foot in length and bear several leaves. The racemes are simple, about 2 feet in length, arching, and bear a large number of flowers. These are tawny yellow in ground colour, with reddish and purple lines and markings, the lip being white, with a few streaks of rosy purple. The culture

of this plant should not be attempted unless a full stove temperature can be maintained. The best position is one not far from the roof glass in a house devoted to Dendrobiums and similar Orchids, where they have abundance of water at the roots and atmospherically during the growing season. When the pseudo-bulbs have finished they need a decided and long rest, and very little water at the roots will then suffice. The habit of growth being so strong and vigorous, the compost must be fairly substantial, and the pots used may be fairly large, but the drainage must be perfect. Plenty of large pieces of crocks and charcoal should be mixed with the peat and Sphagnum. The flower-spikes are produced from the base of the forming pseudo-bulbs at this season, and last well in good condition.

## STOVE AND GREENHOUSE.

### TILLANDSIA (VRIESIA) GLAZIOVANA.

BROMELIADS were some fifteen or twenty years ago very fashionable in France. Here and there in large houses or winter gardens some huge specimens are still to be met with. The

*Tillandsia Glaziovana.* Engraved for THE GARDEN from a photograph sent by Mons. J. Sallier fils, Paris.

accompanying illustration represents a magnificent specimen of *T. Glaziovana* I have grown for years at the Château du Val, near St. Germain-en-Laye. At the place are still some different forms of the plant with narrower or larger leaves, and these variations might account for the different names under which it is known, viz., *T. reginae*, *T. gigantea*, *T. Glaziovana*. The plant under notice attains fully 9 feet in width; the long leaves, leathery and firm, are of a fine glaucous green. These big Bromeliads usually flower before attaining such a large size; they then develop a stout erect spike, carrying numerous whitish flowers with a perfume like Jasmine. From seed I now have nice young plants. In large greenhouses or on a winter garden rockery it is very effective. The species was introduced from South Brazil. J. SALLIER.

*Neully, Paris.*

**Alonsoa acutifolia.**—This is, in all probability, a form of *A. incisifolia*. It can be seen in one of the greenhouses in the Botanic Gardens at Edgbaston bearing racemes of bright scarlet flowers with a dark centre, and continuing in bloom all the summer. It is a singularly bright and effective plant and well deserves general cul-

ture. At one time the Alonsoas were very popular, but they have shared the fate of many other good things—crowded out by elaimants of newer introduction. *A. linifolia* and *A. Warszewiczii* are sometimes grown as annuals; both are scarlet-flowered in common with all the species, excepting *A. albiflora*, which bears long terminal spikes of white flowers, having a yellow eye. This makes a good autumn and winter-flowering plant in a greenhouse or conservatory.—R. D.

**Fuchsia triphylla.**—At the Edgbaston Botanic Gardens Mr. W. B. Latham uses this fine and showy species somewhat largely as a greenhouse plant at this season of the year. It has a somewhat compact habit of growth; the flowers, which are cinnabar-red in colour, are produced in long terminal racemes, the petals shorter than the sepals. When the plants are in full bloom the branches become somewhat pendent and take on a graceful habit. Why this fine and most useful ornamental plant is not more grown for greenhouse and conservatory decoration is a matter for wonder, probably because it is not so well known as its merits deserve. Whether it is capable of being grown large enough to form an exhibition specimen I cannot say, but if it is possible, and were so shown, it would create a sensation; the distinct colour of its flowers would make it tell. It may be added that the fine old Peruvian

*F. corymbiflora* is also in fine bloom at Edgbaston, a tall plant bearing numerous corymbs of flowers being a conspicuous feature in the show house.—R. D.

### EARLY ROMAN HYACINTHS FOR FORCING.

THE earliest importations of these are now to hand and no time should be lost in securing supplies. The tropical heat of the year has been in favour of most bulbous plants, and so far as I can gather our neighbours across the Channel have been equally well favoured in the matter of sunbine. Were all our summers as remarkable for heat in the first half of the year as has been the case in 1895, I am of opinion that good bulbs of these Roman Hyacinths can be grown in certain of our more favoured districts in England. We could not, however, even then mature them early enough, but they might come in useful for the successional and later batches. Could we even do this it might in a measure tend to the reduction in the price of the bulbs, which cannot be bought, forced into bloom, and put on the market with a profit to those forcing the bulbs. Indeed, I am well aware from my own experience, and also that of others who have for years largely forced

these into bloom, that if no second spike comes from the bulb the work is done at a loss. But many will say, why grow them at all unless they are profitable? To this I reply that the majority of large growers for market have customers to cater for all the year round, and in these times it will not do to turn a deaf ear to the constant demand of your regular customers for such a well-known flower as the Roman Hyacinth. The potting, forcing, and later on sorting and bunching of the flowers of say 150,000 or 200,000 of these bulbs are no small items. Yet there are many who grow this number and a few others who grow, or rather force, even larger quantities. One of the chief things in connection with growing these for market is keeping up a daily supply when once they begin. Any break in the supply will quickly have its effect on the customer and must be avoided if possible. As soon as the bulbs arrive unpack them if they come direct from the growers, and turn them out of the bags on to the floor of a dry shed or similar place. Here they will quickly dry if left open for a short time.

Pots and soil should be in readiness, so as to get the whole of the bulbs potted with as little delay as possible. Some, I believe, favour the idea of potting in successional batches over a long season, while the market man generally gets the whole potted as early as possible. In this I think he acts wisely, seeing that the bulbs are ripened in a climate warmer and earlier than our own. By this early potting a maximum amount of roots is ensured before the bulbs are placed in heat—a decided advantage for all the earliest batches. The time of flowering is best regulated by their introduction into warmth. My advice then is to pot all as quickly as possible after they are to hand, and by obtaining an abundance of roots the foundation for good spikes under hard and early forcing will be well laid. The earliest spikes of these Hyacinths are usually seen in Covent Garden Market in October, sometimes quite early in the month; but thus early they are not so good as a month or so later.

So far as compost is concerned, any fairly good open soil is suitable, planting five or six bulbs in a 6-inch pot. Plant firmly, leaving the apex uncovered in the potting. Water thoroughly and allow the soil to dry a little before covering them up. With 4 inches or 6 inches of cocoanut fibre, or half the latter depth of ashes above them, they will want no further attention till required for forcing. In employing ashes for plunging such things, and in particular where the top of the bulb is just exposed, it should be known the ashes are free from sulphur. If used quite fresh from the furnaces the emerging spike and growth may be injured by contact; indeed, this has occurred in my experience, and for this reason the fibre is preferred. When first introduced into warmth a temperature of 70° will suffice, eventually plunging in a darkened frame or pit in a bottom-heat of about 85°.

E. J.

**Gloxinias grown cool.**—Fire-heat is by no means so necessary for Gloxinias as is generally supposed, though of course for early blooming it cannot be dispensed with. Where they have been grown in a warm structure many of the Gloxinias will be now past their best—a very different state of affairs to that brought under my notice a few days ago, when I saw a fine batch of these beautiful plants just coming into flower. They were not needed till the month of August, and having a stock of tubers in hand (the result of last year's seedlings), the following treatment was given them with perfectly satisfactory results. In the first place, they were, when dormant last autumn, laid in shallow boxes of sand and wintered

under the stage in an ordinary greenhouse, the sand being occasionally slightly moistened. Then, as soon as signs of growth made their appearance in the spring, the boxes were stood on the stage and soon afterwards the plants were potted off. When this was done they were placed in an ordinary garden frame on a firm bottom of ashes. Mats were thrown on during the night while any probability of frost remained, and no more air given than was absolutely necessary; while of course, by shutting up early every care was taken to economise sun heat as far as possible, the results being shown in a fine batch of plants bristling with flower buds, which in the early days of August were rapidly expanding. Grown in this way insect pests rarely give any trouble. An excess of moisture must of course be guarded against. The beautiful garden forms of *Streptocarpus* also do well under the same treatment. The fact that *Gloxinias* can be grown in this way has been before now referred to in *THE GARDEN*, but in many places at least their value for late blooming is overlooked.—H. P.

## FRUIT AND VEGETABLE CROPS.

### THE FRUIT CROPS.

JUDGING from what I have seen in various south-western districts, the fruit crops of 1895 may fairly be considered highly satisfactory. There have been heavier crops of some few kinds of fruit in other seasons, but it is not often that so few complete failures can be chronicled. All kinds of fruit trees flowered most abundantly. Both Pears and Plums were exceptionally plentiful last season, and the trees of these are giving the lightest crops this summer. It cannot be too often pointed out how much over-worked trees stand in need of assistance at the roots. Once they have commenced bearing heavily it may be taken for granted the roots have exhausted much of the fertility originally contained in the soil, and a renewal of this should take place before the stunted growth and wholesale dropping of small fruit take place. It is orchard trees and all that have no access to a good food supply in the shape of well-manured garden ground that stand most in need of assistance, and, curiously enough, many orchards in a poor plight are owned or rented by men who have the most opportunities of easily supplying the required manure. Old orchards in which fewer failures are noted are those in which sheep, pigs, poultry, and in a less degree cattle are nearly always present. Those that fare the worst of all are lawn trees. Very many really handsome fruit trees have either been planted on lawns or enclosed of late years, and these prove both ornamental and serviceable. At Mentmore, for instance, there is a fine tree of Blenheim Pippin Apple in the pleasure-grounds that occasionally yields 30 bushels of good fruit in a season, and there are equally large specimens of Apple trees to be seen on lawns in this and adjoining counties, but they only produce heavy crops every second or third year owing, more often than not, to poverty at the roots. So starved are some of these trees that the red spider seems capable of exhausting every particle of chlorophyll formed in the leaves, and both the present and future crops will suffer accordingly. It is the starved lawns and the trees that are established in these and poor ground generally that are invariably the greatest sufferers from drought, and had not heavy soaking rains fallen when they did, many heavily laden trees would have succumbed completely.

PLUMS.—To all appearance the crops are very variable. In some positions and some gardens

the crops on many of the trees are very heavy, in others they are very light indeed, the reasons for which I have already given. In the home counties, and Bedfordshire in particular, Plums grown as orchard trees are undoubtedly profitable, ranking next in this respect to a plantation of Gooseberries. As it happens, these two kinds of fruit succeed remarkably well together, Plum trees being less liable to over-grow the bushes than are Apple, Pear, and Cherry trees. As far as my experience extends in the south-western counties, the Plum has not as yet been largely planted as an orchard tree. I am within comparatively easy distance of the famous Plum orchards in Worcestershire, and know full well what a difficulty the growers in that county have in getting rid of extra heavy crops at remunerative prices. It is also well known that Plums do not travel satisfactorily, and the fruit has therefore to be either got rid of locally, or must be either dried or made into jam, or spoilt. Prices fluctuate surprisingly, and are so low during a plentiful year that it scarcely pays to send the fruit to the larger towns. I have known fruiterers give as much as £1 for a tree of Victoria, this being when Plums were somewhat scarce, and only offer 5s. for an equally good crop, or, say, three half-sieves, in a plentiful season. All things considered, I should say there is room for a Plum and Gooseberry orchard in the neighbourhood of most of our south-western towns, but directly it is found there is "money in it," orchards will be planted in various directions, and none will then pay really well. I hold that the Plum is the least fastidious of fruits as regards situation and soil, but the best results attend planting in a position sheltered on the east side by a belt of forest trees, the latter affording temporary shade from bright sunshine on a frosty morning long enough to bring about a slow and safe thaw. Moderately strong gravelly, or sandy, rather than very clayey loams suit most varieties of Plums best, and some of the heaviest cropping trees I have ever seen are rooting in chalky soils. As a matter of fact, they may be grown successfully almost everywhere. If one variety fails, another may succeed, especially if the stocks are locally raised and grafted. By far the best trees of Green Gage, Victoria, Kirke's, and Orleans I have come across were raised by their owners, and there would be far fewer failures if this plan were more generally adopted. At Lymington, near Ilchester, there are fine trees of Green Gage and Victoria, each carrying not less than three bushels of good fruit, growing on a strong clayey soil, but then these were home raised. New Plums have not gained much headway hereabouts. Sultan, Monarch, Grand Duke, and Czar have all been planted by a few growers, but their size and showy appearance are their principal recommendation. Undoubtedly Monarch, Grand Duke, as well as Prince Engelbert, Pond's Seedling, and Diamond are fine late varieties and among the best that can be grown for the markets, but they are, as a rule, fit for cooking only. Nor have I a very high opinion of the quality of the Sultan, but have found the Czar a moderately early variety good enough for dessert. Not one of them is really equal to a well-ripened Victoria gathered from a tree not too heavily laden with fruit. Unfortunately, the best flavoured Plums, this including the Gage family, Jefferson, and Coe's Golden Drop, when grown as standards are liable to have their fruit much disfigured by winds and rain, bruising and cracking being far too prevalent at times. Neither de Montfort nor Kirke's, two highly flavoured purple varieties, succeed

well in the open, and these, as well as Oullin's Golden, Early Transparent Gage, Denniston's Superb, Green Gage, Bryanston, Reine Claude de Bavay, Jefferson and Coe's Golden Drop are all richly flavoured and worthy of wall space. Wilmot's Early Orleans and Victoria are also fully deserving of room against a moderately warm wall, these often giving crops of really good fruit when most other varieties have failed.

APPLE TREES generally are very heavily laden with fruit, and, thanks to the rains, the size will not be so much at fault as at one time anticipated, though the quality as yet is second rate. With more sunshine we may reasonably expect an improvement in the quality, but if we get little of this during the next month both the flavour and keeping properties will be at fault. Wall trees are fast becoming popular, and I have seen trees of Lord Suffield, Peasgood's Nonsuch, Ribston Pippin, and Baumann's Winter Reinette carrying extraordinary crops of fine fruit. Quarrenden cropped heavily last season, and the trees are again very heavily laden with moderately large highly-coloured fruit. It is very satisfactory to note that Ribston Pippin and Blenheim Pippin promise to be finer, cleaner, and more abundant than is often the case. In some orchards the last named is the only variety that will fetch good prices this season. The cider orchards will be a beautiful sight by the end of this month, the crops being phenomenal.

PEARS.—Second-rate early kinds are fairly plentiful, but the successional varieties, notably Williams' Bon Chrétien, are a light crop, and the same may be said of the greater part of the varieties grown. Even where the trees are fairly well cropped the fruit is under-sized, in consequence of either malformation of flowers or a deficiency of pollen. The only really good crops I have seen are produced by extra fine trees of Beurré Hardy, Glou Morceau, and Beurré Rance trained against house fronts, and the old stewing Pear, Uvedale's St. Germain, is plentiful in places. Only a comparatively few standard Cherry trees are grown in this county, and birds have the bulk of the fruit that is produced. If properly planted, Cherries would succeed well as orchard trees, and there is a good demand for the fruit. Wall trees have given excellent crops, and it is not often Black Tartarian and Morellos are seen so good as they have been and still are hereabouts.

APRICOTS have turned out better than expected. Many of the trees were cropped heavily during the past two seasons, and it would not have been very surprising if they failed somewhat this year. As it happens, there are some grand crops of Moorpark, St. Ambroise, Large Early, Royal, and Hemskirk to be seen, which only want rather more sunshine to bring out their lusciousness. There would be fewer failures with this valuable fruit if the sites were better drained, and a good proportion of chalk, mortar, or lime rubbish mixed with the soil. Apricots will not grow in a soil deficient in lime, and should never be planted in a rich compost, as that promotes a rank, gum-inviting growth at the outset.

PEACHES AND NECTARINES were much affected by leaf blister early in the growing season, but have rallied surprisingly, and good crops are the order of the day. Waterloo, Early Alexander and Amsden June have already given ripe fruit, but the rains cause the more forward to crack rather badly.

FIGS.—In the neighbourhood of Wells, and again near Yeovil, I have noted good crops of White Marseilles and Brown Turkey, the less

reliable Brunswick and Negro Largo also giving a few fruits.

GOOSEBERRIES were a heavy crop, but those who tried to save any to ripen must have been disappointed with the flavour of most of them. Only Whinham's Industry and Red Warrington have kept well, and the flavour of the former is second-rate.

BLACK, WHITE AND RED CURRANTS all gave very heavy crops, but the first-named ripened somewhat prematurely in the strong, dry heat prevailing. Raspberry canes were much crippled by frosts, and the crops of those uninjured suffered from the drought.

STRAWBERRIES promised to be unusually plentiful, and so they were for a short time, but the drought spoilt the crops in many places. It was the old beds on shallow, hot soils that suffered the most. Royal Sovereign gave great satisfaction wherever given a fair trial. Filberts and Cobs are only moderately plentiful, but I never remember seeing the Walnut trees so heavily laden as they are this year.

Somerset.

W. IGGULDEN.

## SOUTHERN.

**Aldenham House, Elstree.**—The fruit crops here and in this locality are, on the whole, good, and except in a few cases show little ill effects of the past severe winter. Raspberries were almost ruined, most of the canes being quite killed. Figs on walls that were not protected were killed to the ground. Having a good depth of soil resting on clay, we did not suffer during the late drought so badly as some people. Up to July 17 we had only registered 7.70 inches of rain, our average fall for the year being 24 inches. From July 17 to 30 we have had 4.34 inches. I never saw the Apple crop look more promising. The trees are clean and the fruit swelling very satisfactorily. Very fine are King of the Pippins, Cox's Orange Pippin, Scarlet Pearmain, and Hanwell Souring. Pears a fair crop. Plums good. Apricots much under the average; the trees bloomed but very little. Cherries of all kinds excellent; also all kinds of small fruits, except Raspberries. Nuts of all kinds plentiful.—EDWIN BECKETT.

**Mereworth Castle, Maidstone.**—There is a very good crop of Apples. Blenheim look well, and the trees are in most instances heavily cropped. Lord Derby, Warner's, and many other earlier sorts are also producing an abundance of fruit. Pears scarce. Nuts a fairly good crop. Peaches and Nectarines good. Cherries excellent; the dry weather just suited them. Of soft fruits there have been good crops, but the season, owing to drought, was very considerably shortened. Damsons good, but Plums thin.—H. MARKHAM.

**Bristol House, Putney Heath.**—The Apple crop is very good in this neighbourhood, and since the rain swelling up fast. Pears average crop. Plums medium crop. Peaches and Nectarines good crops, trees clean and healthy. Morello Cherries good crop and fruit fine. Red, White, and Black Currants good. Raspberries small at first, better since the rain. Gooseberries good crop, but the weather was too hot for some of the sorts in the full sun, although mulched and watered. Strawberries good both in quantity and quality. Peaches and Nectarines never suffer from blister here. Cellini and Ribston Pippin Apples are free from canker and constant bearers.

Vegetables on the whole very good. Brussels Sprouts, Kales, Broccoli, &c., are looking well. Onions smaller than usual; also early Potatoes on poor, light soil, but on good soil Potatoes are very good. The soil here is light, and the sub-soil a loose sandy gravel. The garden is just level with the top of the cross on St. Paul's, so that a dry, hot season affects it very much, and

entails much labour in mulching, watering, &c.—WM. STANBURY.

**Addington Manor.**—Generally speaking, notwithstanding the intense and long-continued frost we experienced in the month of February and the almost unprecedented rainfall up to the end of June (6½ inches), both vegetable and fruit crops have done very well indeed in this locality. Strawberries an immense crop, assisted only by one good watering during the dry period. Raspberries and Currants of all kinds fine crops; also Gooseberries where the bushes were not injured by the bullfinches. Plums and Pears a good average. Apples on espaliers and on young trees good crops.

Some vegetables, such as Brussels Sprouts, the different kinds of Kale and Broccoli, were rather severely handled by the February frost, particularly between the 6th and 10th. Summer crops without exception have done and are doing well. We have had plenty of rain since July 18—rather over 3 inches.—J. MATHESON.

**Poles, Ware.**—The Strawberry crop has been exceptionally good in this locality, notwithstanding the dry season. Laxton's Noble, Duke of Athol and Sir J. Paxton among early sorts, and Dr. Hogg and Latest of All, of late kinds, have withstood the drought better than other varieties. Raspberries a heavy crop, though the fruit is small. Hornet is unquestionably the largest fruit and freest bearer of any grown here. Black Currants abundant, as also Red and White, but owing to the dry weather the birds considerably thinned the two latter. The Gooseberries also suffered from the same cause, but at an earlier date, the bushes having been denuded of buds. Cherries (sweet) a good crop; Morellos good. Plums planted against walls in the various aspects are carrying a heavy crop. Standard and bush trees, with the exception of Bullaces and Damsons, are very thin. The same applies to Pears, the cordons especially promising well. Apricot trees died back more than ever this year; the blossom was very sparse, but distributed fairly over the sound branches of the trees, and owing to the excellent weather they had during the setting period the crop may be called a fair one. The Apple trees are heavily laden. The crop of Quinces is exceptionally heavy. Peaches out of doors are promising well; Hale's Early and Early Alexander are being picked now (July 25), and are remarkable for their flavour and high colour. Medlars and Filberts are promising well.—A. WALLACE.

**Caversham Park, Reading.**—The winter did great harm to the kitchen garden crops; Cabbages, Lettuces and Globe Artichokes were destroyed, and, with the exception of Late Queen Broccoli and Sutton's Safeguard, the garden was bare of vegetation; in fact, the most total destruction I ever remember. Shrubs also suffered very much. Fruit trees seem to have benefited, for never do I remember better and cleaner crops of many kinds. Strawberries a good crop, although some varieties appeared almost destroyed, especially James Veitch, which is not so hardy as other kinds, a fact I only discovered this year, particularly those in pots which did not force well after the severe winter; nothing but the crowns survived. Plants of the same kind in the open beds gave fair crops, yet these looked as if a fire had gone over them. Most of our Strawberries gave an average crop, all small fruits the same, Gooseberries being the only exception. The most noticeable feature of the fruit crop here is the entire absence of insect pests, Plums, Peaches, Cherries and other trees being perfectly clean. I cannot say the Pears and Plums are as heavily cropped as last year, but there is enough. Apples we have had to thin, and although the dry weather has been of long duration, the trees remain healthy, the fruit of an average size.

With the exception of Peas, vegetables have been very good, especially on well-trenched ground. Scarlet Runners came in earlier than I ever remember. Potatoes where planted early are very good, but I fear where the haulm is left they will grow out a good deal; no disease has been found. Now plenty of rain has fallen the crops

generally are looking well, although on the light chalk hills near here, where crops were put in late, I fear a total failure will ensue.—CLAS. FLOTT.

**Buxted Park, Uckfield.**—The season of 1895 will in this district be long remembered as one of the best, taking it all round, for hardy fruit; true, there are some blanks and slight crops amongst the Pears and Plums, but, as a rule, all others are a full crop. On looking over our orchards containing 100 or more of the leading kinds of Apples, there are but few that have to be recorded as blanks, and in many instances the trees have to be severely thinned to induce the fruit to swell to anything like its full size. Our soil is a heavy loam, of poor quality, resting on sandstone rock containing a large percentage of iron, which has the effect of causing some varieties to canker badly, such, for example, as Tom Putt, Herefordshire Pearmain, Golden Harvey, Lord Suffield, Golden Russet, Ribston Pippin, New Hawthornden, Cellini, Claygate Pearmain, and others. On the other hand, there are many varieties that grow exceedingly well, and amongst these I may mention Mabbott's Pearmain, Seaton House, Brownlee's Russet, Loddington, Baldwin, Sandringham, Baumann's Red Reinette, Tower of Glamis, Bramley's Seedling, Mannington's Pearmain, Golden Nonpareil, Ecklinville, Lady Henniker, Duchess of Oldenburg, D. T. Fish, Alfriston, Yellow Ingestre, Cox's Pomona, Lane's Prince Albert, The Queen, Pott's Seedling, Yorkshire Greening, and Hanwell Souring. There are a few varieties which have no fruit this season, but why this should be so I do not understand, seeing that they flowered well and were treated in every respect like the others. Amongst these are Flower of Kent, Gloria Mundi, Sturmer Pippin, Gooseberry Pippin, Cornish Gilliflower, Waltham Abbey Seedling, Golden Knob, Gravenstein, Kentish Fillbasket, and American Mother. In early spring some of the trees were infested with the caterpillar, but to no great extent. Owing to the long spell of dry weather the fruit is not so large, but since the rains it has swelled wonderfully, so that we may hope for good samples where the trees are healthy. On walls the crops of Pears are fair, but in the open there are not many kinds that have a full crop. Amongst those varieties that call for special mention in this respect are Souvenir du Congrès, Marie Louise, Passe Colmar, Jargonelle, Fondante d'Autonne, and Citron des Carmes. Plums for the most part in the open are a failure; there are some, however, that are carrying fair crops, such as Blue Perdrigon, Orleans, Early Rivers, Prince of Wales, Monarch, Archduke, McLaughlin, Victoria, Cox's Emperor, and the Czar. These kinds seem hardy, having suffered but little from the severe winter, though on our strong soil they make robust growth. Damsons suffered with us very severely last winter, especially Frogmore Prolific and Shropshire, most of the young shoots and many of the older ones being split by the frost and killed. Farleigh, however, did not suffer so much, and this is giving us a few fruits from late blooms that opened in May. In most places in this district Damsons do fairly well, particularly the Cluster. On heavy soils Plum trees make too sappy a growth, which does not always get well ripened; hence the reason they suffer so much in winter. Where the soil is moderately light and well drained they do fairly well, especially those previously named. Many of the new varieties are of first-class quality, especially when grown against a wall, and though the present is not a favourable season some are carrying good crops. Late Rivers, though it does no good in the open, is very good on a north wall; the same may be said of Grand Duke. This fine Plum cannot be too well known. Monarch, La Delicieuse, Washington, Coe's Golden Drop, McLaughlin, Kirke's, Archduke, and White Magnum Bonum are all useful when planted on this aspect. Amongst the best flavoured Plums when grown on a south or west wall I may name Green Gage, Jefferson's, Kirke's, Transparent Gage, Bryanston Gage, Angelina Burdett, Coe's Golden Drop, and McLaughlin. Cherries have

been an abundant crop, and the fruit has been finer this season than I ever remember it. Florence has been extra large, many of the fruit being nearly  $3\frac{1}{2}$  inches in circumference from trees growing on a north wall. Morellos, too, are very good. The dry season on our cold, heavy soil seems to have suited them. Apricots are a full crop. As a rule these do not do so well on our wet land, but this season seems to have suited them admirably. Peaches, though they suffered somewhat from blister in the early part of the season, have now outgrown that malady and are carrying fair crops of fruit. Bush fruit of all kinds has been plentiful, and though Black Currants were not so large as we sometimes have them, Lee's Prolific and Black Naples were both very good. The Red varieties were exceptionally fine, particularly Red Cherry, Raby Castle, and Grape. Gooseberries where the bushes did not have the buds picked out have been an excellent crop, the fruit being both large and of good quality. Raspberries suffered much from the frost, many of the canes being killed to within a foot of the ground. The dry weather, too, has had a serious effect on the fruit, for it has neither been so large nor so well flavoured as in some more favourable seasons. Superlative and Prince of Wales have been the best; both of these kinds are still giving us some good fruit, and though somewhat damaged by the heavy rains, it is still very useful. Strawberries were a most abundant crop with the exception of some of the more tender kinds, which were killed by the late severe winter. The fruit, however, in many instances was small and without that juiciness it has during a more favourable season. Still where the ground was in good heart and from young plantations some of the fruit was exceptionally fine. Strawberries as a rule do not suffer much during a dry season on this soil, for, being so close, it holds the moisture, particularly if mulching is done before the ground gets dry. Nuts are very plentiful, though Cobs are not quite such a heavy crop as I have sometimes seen them. Filberts and Walnuts are very full. Mulberries and other bardy fruits of a less interesting nature are more plentiful than in some seasons; therefore, taking all into consideration, this may be considered one of the most favourable fruit seasons we have had for some time, and though there may be a lack of Plums and Pears, this is more than counterbalanced by the splendid crops of Apples and other fruit.—H. C. PRINSEP.

**Old Warden Park, Beds.**—Apples are a good average crop, trees very healthy and the fruit swelling freely. Pears are generally a very thin crop, fruit small on bush and standard trees, but better on walls. Cherries are a good average crop, but rather small. Plums under average on bush and standard trees, better on walls. Apricots very scarce indeed, but the trees are very healthy and free from insects. Peaches and Nectarines on unprotected walls are good; the fruit is rather small, owing to the drought, but improving since the rains. Strawberries are over average; the best results follow on well-cultivated ground, deeply trenched and well manured. Raspberries, Gooseberries and Currants exceptionally fine. I consider Superlative the best Raspberry grown. Nuts over average, Walnuts exceptionally heavy crops.

Early Potatoes are good, but crops very light, owing to the long drought. Late varieties are looking very promising after the late rains. Beans, Peas, Cauliflowers, &c., have been scarce and rather poor, owing to the long drought.—G. R. ALLIS.

**Elvetham Gardens, Winchfield, Hants.**—The past winter does not appear to have injured the fruit trees to any serious extent, but it was most disastrous to Roses, shrubs and conifers. The fruit crop here varies. Pears average, Plums partial, Apricots on open walls failed to flower; Peaches, where protected, average crop. Apples are a good crop, and the splendid rain we had on the 18th July and following days will help to swell them up to a good size. Strawberries have been abundant and good, but from the intense heat and drought were soon over. Raspberries,

Gooseberries, Red, White and Black Currants average crops and fruit fine. Cherries a splendid crop.

Early Potatoes very light crop, but good in quality. Rainfall for the month of July, 4.59 inches.—THOS. JONES.

**Stanmore Park, Bishop's Waltham, Hants.**—On the whole the present must be regarded as a good fruit season in this garden and in the neighbourhood. The recent long spell of dry weather hastened the ripening of bush fruit, and prevented it becoming so large as usual. Apples dropped a good deal, too, in consequence, when they should have been taking their first swelling. Insect pests have not been nearly so troublesome as might have been expected. Here and there can be seen a few orchards where Apple trees especially are defoliated—the work of caterpillars, but where care has been taken to prevent ravages of this kind, there is little cause for complaint. The average rainfall in this neighbourhood is 30.0 inches. Up to the present date (July 24) we have registered but 12.80 inches. During the months of May and June but  $1\frac{1}{2}$  inches of rain fell. Strawberries are largely grown in this neighbourhood, some hundreds of acres being under cultivation, for supplying such centres as London, Oxford, Birmingham, Manchester, Liverpool, Edinburgh, Glasgow, and even Belfast. From one small station—Swanwick—on the Fareham and Netley line, as many as 32,000 gallon baskets were sent away in one day (June 17), and for the six days following no less than 98,000 gallon baskets were dispatched from this one small station. This number represents no less than 262 tons of fruit, or a daily average of 43 tons. I mention these few facts to show to what an extent Strawberry growing has reached. This year picking commenced May 31. But few varieties are grown. Noble ripens its fruit first, followed by Sir J. Paxton and a local variety named Garnier. Sir J. Paxton is the sheet-anchor of the market men. Where one acre of any other variety is grown one hundred of this is cultivated. The crop was an extremely heavy one and the fruit of excellent quality, especially so where the subsoil is clay. It was considered to be much the best Strawberry crop for many years. Apples are a full crop, while the quality promises to be good. Where the soil is heavy the Apple scab is making its appearance upon the skin of some early varieties, notably Irish Peach, owing presumably to the warm showery weather experienced during the last ten days. The trees as a rule are exceptionally clean; red spider has attacked the leaves of some, but taken as a whole capital growth is being made by the trees carrying a full crop of fruit. Such varieties as Warner's King, Ecklinville, Mère de Ménage, Lord Suffield, Lord Grosvenor, Alfriston, Lane's Prince Albert, New Hawthornden, Yorkshire Greening, Hollandbury, Golden Spire, Keswick Codlin, and Grenadier are exceptionally heavily laden. Amongst dessert varieties, Blenheim Orange, Cox's Orange Pippin, Devonshire Quarrenden, Irish Peach, King of the Pippins, Ribston Pippin, Pine-apple Russet, Beauty of Hants, Red Astrachan, Lady Sudeley, Margil and Ceckle Pippin have exceptionally heavy crops of fine fruit. Pears are rather thin, especially upon trees in the open. Wall trees have a fair crop of clean healthy-looking fruit. Marie Louise, Jargonelle, Pittmaston Duchess, Louise Bonne of Jersey, Fertility, Souvenir du Congrès, Beurré d'Amanlis, Winter Nelis and Passe Colmar have the best crops. Peaches are carrying heavy crops of good fruit. The trees look uncommonly well in spite of the severe winter. Some few late-ripened shoots were injured during the winter, but the trees are now well furnished with new growth. I gathered the first fruit of Alexander from a tree against a south wall on July 20, and from a tree of Waterloo on a west aspect I gathered ripe fruit on July 26. The latter-named is much the best of early outdoor Peaches; not only is it superior in flavour to Alexander, but it grows to a larger size. Grosse Mignonne, Bellegarde, Hale's Early, Dymond, Early Louise, Late Admir-

able and Walburton's Admirable succeed well every year. Cherries have borne immense crops of large handsome fruit, especially trees against walls. Varieties like Governor Weed, May Duke, Elton, Bigarreau Napoleon and Black Tartarian against a west wall have carried and ripened magnificent crops of fine fruit. Morellos on a north wall have borne equally heavy crops. The foliage is particularly healthy and large. There has been almost a total absence of black fly this season. Raspberries suffered much from frost; many of last year's canes were killed quite down to the soil. This applies especially to heavy soil, proving that the wet weather was not favourable to perfect maturation of the canes. Where they did escape the crop has been a heavy one, but owing to the continued drought the fruit was somewhat small. Superlative and Northumberland Fillbasket were the best varieties. Gooseberries and Currants of all kinds have borne heavy crops of good fruit. In some few instances the Gooseberry trees were slightly affected with red spider, but where prompt means were taken to check this pest but little harm was done. Walnuts and Filberts are bearing heavy crops; in fact, I never saw trees of the former carrying such a load of Nuts. Plum trees upon walls are heavily laden with very fine fruit. Such varieties as Orleans, Victoria, Green Gage, Jefferson, Washington, Kirke's and White Magnum Bonum are especially noticeable for their heavy crops. I never saw the foliage looking so healthy as at the present time.—E. MOLYNEUX.

## GARDEN FLORA.

### PLATE 1027.

#### THE APHELANDRAS.

(WITH A COLOURED PLATE OF APHELANDRA NITENS.\*)

To me it has been oftentimes a matter of very much surprise that these handsome plants have not been grown more extensively in private gardens. By many they do not appear to be known sufficiently well to claim at least a small share of attention. They have many advantages in their favour as decorative plants, whilst the showy spikes of flowers in a cut state are totally unlike anything else. These spikes, be it noted, may be cut in most cases of considerable length without any harm to the plants. The season of flowering extends from August in the case of A. Leopoldi, to December in that of A. aurantiaca and its dwarf form, A. aurantiaca Roezli. This covers a season when plants of such distinct and showy character are indispensable in many gardens. As market plants they can scarcely be recommended unless it be in the case of the last named variety. This, however, instead of being in the slightest degree against them, is, on the other hand, in their favour, in my opinion, by reason of their distinct character.

Aphelandras are all of easy growth, thriving well in any average stove temperature, their culture coming under the same head as that of Justicia and Scutellarias, save in that they are best kept at all times in the stove, whereas both of the last named genera may be grown in a cooler temperature during the summer. After flowering they should be kept more on the dry side so as to give a partial rest, being again started into growth in the spring, as with Allamandas and Clerodendrons. Thus they take but little room for from three to five months out of the twelve; this alone is a feature worth noting. When quite rested and the foliage dropped or dropping, they may be pruned back to the base buds of the previous growth, then the pots can

HERB. GARDEN  
AUG 17 1895

APELANDRA NITENS

be stood closely together, but the soil should not be kept absolutely dry so as to cause the wood to shrivel. At such times a shelf is not at all a bad place for them or a pit with a temperature not lower in cold weather than 55°. A good time to start the earliest flowering kinds is during February and the latest in March. The omission to carry out the pruning as indicated will result in leggy plants and a less vigorous growth; do not therefore omit it on any account. The balls should be reduced at the time of re-starting, just as with Poinsettias, so as to allow afterwards of an additional shift when this is seen to be needed as summer progresses. Avoid overpotting at all times, so as to keep a good proportion between the plants and the pots. The best soil to use is light loam and peat, or good leaf soil in place of the latter if more convenient, sand being used freely and firm potting carried out. No stimulants will be required until the flower-spikes begin to show, then slight applications will assist the free-growing kinds. Propagation is easily carried out either by cuttings or by seed. The young shoots in the spring strike freely enough when taken off with a heel, using nearly all sand, and plunging in bottom-heat with plenty of atmospheric moisture to prevent any drooping of the foliage. These plants for the first year should be grown on without stopping, thus carrying one spike to each in the respective season. Older plants, it should be noted, may need one stopping, so as to equalise the vigour of the shoots. But little shade is needed, the object being not so much that of securing large foliage as a close compact growth. The usual system of

#### PROPAGATION

appears to be by means of cuttings, but from practical experience I have found in the case of one variety at least that seedlings are preferable; whereas in that of others when the seed ripens by all means make use of it as a means of increase. The variety in question is *A. aurantiaca* Roezli, which as a dwarf decorative plant is extremely useful in small pots, flowering from seedlings when less than 1 foot in height. The seed-pods must be closely watched, otherwise when searched for the seed will be found to have vanished, the seed capsules having a propelling power furnished in some way when they burst, so that the seed is scattered to some considerable distance beyond the pots. To prevent the loss of seed in this way it is a good plan to tie each seed-bearing spike up in tissue paper as this stage approaches, or else to watch very closely and cut them off as soon as the lowest pods show signs of bursting. The seed may be sown at once if need be, or within a few weeks if more convenient from point of warmth, being afterwards carefully attended to as seedlings, first as to pricking off when sufficiently large, and then potting singly into small sixties, afterwards giving a shift into large sixties, or into forty-eights in the case of the strongest plants. These seedlings should never be potted the first year into larger pots. A good position to keep them in will be a shelf, so that plenty of light is afforded in order to keep the growth close and compact.

The usual insects that infest stove plants will give trouble if not properly guarded against, the worst of these being the mealy bug and the brown scale; the black thrips will also disfigure the foliage, but all of these may be kept under with ease, bearing in mind the many efficacious present-day insecticides.

#### VARIETIES.

There is some considerable diversity in the varieties under cultivation in habit, foliage, and the colours of the flowers.

*A. NITENS*, the variety now forming the coloured illustration, is in every respect quite distinct; the growth is close and compact; it has dark coloured foliage, lustrous or shining on the upper surface and dark vinous purple beneath, being also of a leathery substance; the colour of the flowers is well indicated in the plate. This species was introduced by Messrs. J. Veitch and Sons from Colombia, having been first distributed about twenty-five years back.

*A. AURANTIACA* is one of the oldest kinds grown in gardens, as it is one of the best for flowering from October to December. When in bloom it makes a most brilliant display, its dense branching spikes being very fine; the flowers are of a rich orange-scarlet shade and are produced in succession for some considerable time; the foliage is somewhat large, dark green in colour, with a pale silvery grey suffusion. I have grown this variety as a specimen with from ten to twelve growths and as many spikes, thus making a brilliant display.

*A. AURANTIACA* ROEZLI is a dwarf form of the preceding with the silvery suffusion on the foliage much more decided. As a dwarf plant of compact sturdy growth it is quite a gem when well managed (as from seedlings). It flowers during December, being good at Christmas time; the flowers are brighter in colour than those of the type, whilst the spikes are not so large. As a decorative plant in its season it is one of the very best.

*A. CRISTATA* is the oldest species under cultivation as it also is one of the very finest. A few years ago Mr. Bain showed it in splendid condition from Sir Trevor Lawrence's collection at one of the R.H.S. meetings; the spikes then shown were very fine, proving at once its claim to far more notice. The growth is of the two more robust than in *A. aurantiaca*, whilst the foliage is of a darker green and also larger; the flower-spikes are more branched and the individual blossoms larger as well. This species in the time of specimen plant growing used to form a striking object at the autumn shows of the old Brighton Society from Mr. Atkins when at Viscount Gage's, Firlie Place, Sussex.

*A. LEOPOLDI* is a variegated variety, more striking perhaps in its foliage, which is dark green with white venations; the habit is compact, but the growth is rather slow; the flowers in this instance are of a rich shade of yellow.

Three other distinct varieties are *A. Portana*, *A. fascinator* and *A. punctata*.

SOUTHRON.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**EARTHING UP LEEKS.**—Where early Leeks are a speciality, those which were raised in heat in January will by this time have grown to a good size and may be partially earthed up. Where several rows are in one trench great care is necessary in order to prevent any soil from getting into the centres of the plants. A good way to prevent this is first to tie a band of soft matting round the lower part of the plant and to use a thin board, this being held by one man against the row while a second puts in the soil with a spade or shovel, the board afterwards being lifted gently out and the soil worked around the stems with the hand. When only one row is grown in each trench it may be earthed up so far similarly to Celery. Leeks being such thirsty subjects, it will be well, in spite of the copious rains which have fallen of late, to give the trench a good soaking with farmyard liquid the day previous to earthing; this will greatly aid the plants to swell out at the base during the final stage of growth. Successional lots coming on either in trenches or on the level ground must now be looked to and kept free from weeds, as if these are permitted to accumulate, the same evil, namely, dirt entering the centres, is liable to follow. In cleaning if the weeds have grown tall, hand-weeding in the first place is the

best, using the Dutch hoe afterwards, the same remarks being equally applicable to young Lettuces and Endive, which are easily spoiled by the soil getting into the hearts.

**SOILING CAULIFLOWER.**—The principal sowing of Cauliflower which is to be planted out in hand-lights as a first early batch for cutting in May should now be made. I prefer an east border, as then should the weather be very favourable to growth the plants are not so liable to get too forward by transplanting time as when grown on a sunny south border. The small forcing varieties should not be sown now, spring being the best season for this, in a gentle warmth in boxes. I am sowing Walcheren and Pearl, the former coming into use first by about ten days, and being less liable to button than Early London, unless one has a special strain of his own. Sow broadcast, covering with a fish-net to protect from birds. Where plenty of room can be spared for early Cauliflowers, other varieties may be sown. Eclipse, although strictly speaking a late summer and early autumn variety, may be sown now to follow the sorts above-mentioned, and indeed some gardeners sow Autumn Giant at the end of August and beginning of September for producing heads during July. Thus treated, Autumn Giant does not grow to such a large size and is most useful for table. Be careful not to sow the seed thickly, as in wet weather the young seedlings if crowded soon damp off. Thin out as soon as the plants can be handled, this being not only better for them, but a saving of labour as well. The sooner now the plot for these early Cauliflowers is prepared the better, choosing ground that has not grown any member of the Brassica tribe for some time, and that has not been smothered up with foliage of any kind throughout the summer, as a sweet, healthy root-run is very essential for this crop, the reverse only encouraging grubs and clubbing. Incorporate a good sprinkling of fresh soot and a little gas lime or burnt refuse, and avoid rank green manure, this frequently containing the germs of destructive insects, which ruin the plants in their infancy. The seed for producing plants for wintering in pots or frames should not be sown until the very end of the month or first week in September, or the probability is they will be far too forward for the purpose, and will button in even while in the frames. This is a mistake only too commonly made. Where Walcheren growing on Celery ridges is now hearting in, the outer leaves should be bent down to protect the heads from sun and air both for the purpose of retarding them and preserving the colour. If a glut is feared lift the plants and lay them in behind a north wall, well soaking the roots; here the heads will last in an eatable state for some time. I have frequently kept Cauliflowers wanted for exhibiting for ten days by lifting them in the nick of time and putting the roots, with as much soil attached as possible, into a tub of water, this just covering the ball, and placing them in a cool, dark room.

**WINTER TURNIPS.**—In midland and northern localities from August 10 to 15 is a good time to sow the first lot of Chirk Castle Blackstone Turnip for winter use. If advantage was taken of the clearance of early summer crops to prepare the ground according to previous advice, it should now be in good order for the seed. This should be sown broadcast and not too thickly, a surface sowing of guano or some approved fertiliser being given as soon as the crop is thinned. Orange Jelly is a good winter Turnip, and although perhaps not quite so hardy as Chirk Castle, will stand severe frost without succumbing. I advise a second sowing of the latter about the first week in September, as even during frosty weather this Turnip will increase slowly in size and come in most useful at the new year. Where the soil is light and stony it is a good plan to run the garden roller over the surface after sowing. A watch must be kept as soon as the plants appear, as fly will sometimes play havoc even at this advanced time of year; dusting with lime and soot or wood ashes will check the pest, and also assist

the crop to make a free growth. The best and most open position need not be selected for this crop, as Turnips will do very well even in the partial shade of trees.

**TRANSPLANTING COLEWORKS.**—The plants resulting from the first sowing of this useful vegetable will now be ready for putting out, and as the ground, both of seed beds and open quarters, is in a moist condition, transplanting should prove an easy operation. As I previously stated, I always plant a quarter from which old Strawberry plants have been removed, and in this case drills are not necessary, as the ground, being close beneath, retains the moisture well. On loose, freshly-prepared ground, however, drills will be necessary. Plant 15 inches apart all ways and water home, keeping a sharp watch for underground grubs, which are usually very troublesome in newly-planted Colewort beds. Lime applied to the surface is of no use whatever for this pest, nothing but searching beneath the soil round the stem that has been cut off being of any avail. Several transplantings, even of the first sowings, may be made as the plants get large enough, and the later sowings, which will be ready for putting out at the beginning of September, will afford nice useful heads in January and February. Where sowing has not yet been done no more time should be lost.

**ONIONS.**—The final cleaning by hand-weeding of spring-sown crops of Onions must now be given, as also one more broadcast sprinkling of artificial manure; this will carry the crop on to maturity. Where thick necks abound, go over the bed with a rake and bend down the tops over the bulbs to check the flow of sap and assist in swelling out the bulbs. These, after storing, should be used first, as they never keep so well as thinner necked bulbs.

**SOWING TRIPOLI ONIONS.**—As a rule, the present is a good time for getting in the seed of Tripoli varieties, and if the ground was prepared a few weeks ago, as advised, so much the better, as firmness is one of the best guarantees of a satisfactory growth both in autumn and spring-sown Onions. Avoid thick sowing, as the spring bulbs are much loosened by thinning when this is the case, which allows of their being blown about by wind and weakened by frost at the base. After sowing the seed, give a good sprinkling of burnt refuse or wood ashes in the drills before covering in, then tread and retread the surface, using the roller where the ground is light and shallow. For an early white Onion the old Queen is most useful, doing its work in less time than any other of this section. I have lately sown several sorts of the so-called spring Onions at the same time, and find them equally as hardy as the Tripoli, Trebon and Cranston's Excelsior being two sorts especially suitable for autumn sowing. Where young Onions are likely to be in request in autumn for salads, I would advise sowing an extra row rather thickly, so that the main batch may be freely thinned out when in quite a young state.

J. CRAWFORD.

### HARDY FRUITS.

**PEACHES AND NECTARINES.**—I never saw these trees looking better than at the present time. The hot weather brought on the American kinds earlier than usual, Alexander and Amsden June being ripe the second week in July on a south-west wall. Such kinds as Condor, Hale's Early and others are now giving nice dishes. Nectarines are bearing freely and look most promising. Unfortunately, we have not got any very early Nectarines, and should the new kinds prove good in the open they will be of much value. Now is a good time to assist trees bearing heavy crops in the way of liquid manure and a mulch of decayed manure on the surface, giving heavy soakings of water about twice a week on light soils. These trees often suffer from want of moisture at the roots and red spider attacks them, causing the fruit to be small and worthless. The trees being planted close to walls, are often dust-dry at the roots in such seasons as we have had recently.

Canker and disease would be arrested by giving more food and moisture and getting a clean, free growth. It is surprising what a lot of moisture these trees will take when in a vigorous state. Giving ample food and moisture at this season takes less time than applying remedies to counteract disease. When applying manure in a liquid state it is best given in the evening or in dull weather, and those who cannot obtain good liquid may with advantage give a liberal top dressing of some artificial manure. The final thinning of the fruit of late kinds should now be attended to, and leaves cut away to give colour and good flavour. Any shoots should be tacked in if required for covering bare places and the leaders given support. The removal of foreright shoots should receive attention, and those bearing fruit may be cut back to within three or four buds of the fruit. With wall trees thinning out of useless shoots is an important work, as crowding means unripened wood.

**PROTECTING THE FRUIT.**—Ants have been troublesome among the early Peaches and Apricots, and I find they do not like going over sawdust soaked with petroleum placed at the base of the trees. Slugs will also be a nuisance after heavy rains. These are readily got rid of by persistent looking after at night. They are also readily trapped by placing large Lettuce or Cabbage leaves near their haunts and destroying them when found. Wasps promise to be numerous, and probably we may get as many as in 1893. They can be readily caught in large-necked bottles half filled with beer and sugar. Scott's wasp destroyer is also efficacious, but should be used with care, being poisonous. Earwigs are often troublesome, and should be trapped with hollow Bean stalks and small flower-pots filled with hay. A light covering of tiffany or muslin will protect the ripe fruit for a time, but if covered long the foliage suffers.

**APRICOTS.**—These require copious supplies of moisture, and even when the fruit is cleared there should be no lack of attention in the way of food and moisture. The trees should be encouraged to make strong leaders, these being often the salvation of the trees, and the earlier these strong growths are matured the better. Continue to stop foreright shoots; in fact, these are best pinched in a small state with the finger and thumb, not using the knife. Syringing overhead should be continued for some time after the fruit is cleared. This will keep red spider clear of the foliage and the young growths will mature sooner if growth is assisted. Mulching should not be neglected, as there is ample time for the roots to lay hold of the rich food given. Trees that have become bare by loss of branches may at this time have the shoots laid in, thus furnishing blank spaces, and by training now the growth will be better matured. Late varieties with heavy crops should be liberally fed, and young or newly-planted trees kept nailed to the wall to prevent loss of branches during high winds.

**PLUMS** are cropping very freely in most districts and are very early, such varieties as Rivers' Prolific and Favourite being ready the third week in July. These two varieties are valuable where early Plums are required. The latter is very fine grown on a wall and a sure cropper. With later varieties no time should be lost in feeding and keeping the foliage clean. Aphid this season has been troublesome. Those who have a good water supply can hose their wall trees and thus remove a large portion of the fly, but it does not kill them entirely. I have found Bentley's quassia extract the most useful. Plums that crack badly should be gathered a few days before using, and it is well to go over the trees before cleansing, removing useless shoots and laying in young growths, remembering that next year's crop will largely depend upon the young wood made this season. With trees ripening their fruits and in a dirty state it is not safe to use insecticides, as the fruit would suffer, and in their case clean water must be depended upon. Plums, unlike Peaches, do not like being denuded of their leaves, as the fruits colour freely when slightly shaded. To

preserve the best late kinds it is well to shade with tiffany, and in removing shoots the growth of the tree should be considered, as some dessert kinds make little wood and require more care in stopping. Very heavy crops of any of the large cooking varieties should be thinned.

**CHERRIES.**—The trees, with the exception of Morellos, having ere this been cleared of the crop, daily syringing after a day's hot sunshine will retain a healthy green appearance and plump up the fruit-buds for next season. On light soils canker and loss of branches follow drought, and in heavy or clay land the surface roots should be encouraged by a good mulch of short manure. Morellos need covering with nets, as when fully ripe they protect them from hot sun and shrivelling.

**PEARS.**—These are now turning in. Such kinds as Jargonelle and Williams' Bon Chrétien are better gathered a few days in advance of using; indeed, if sent long distances it is well to gather them when quite firm, as they ripen rapidly. The early kinds, such as Doyenné d'Été, are not worth eating if left on the trees till quite soft, as they are then flavourless. Later kinds bearing heavy crops should be fed freely with liquid manure or a good fertiliser, the latter well watered in and a mulch given afterwards. Owing to drought and heat red spider in some soils will be troublesome, but may be got rid of by well syringing the wall trees at sunset. The lateral growths of cordon-trained trees should be stopped, but the leaders must be nailed in if the trees have not filled up the allotted space.

**APPLES.**—The early varieties of eating Apples, such as Mr. Gladstone, Irish Peach, and Red Juneating, like early Pears, are best gathered before they are quite ripe. These will be followed by Devonshire Quarrenden, Worcester Pearmain, and Lady Sudeley, and need not occupy the winter store, room being found for them elsewhere. If the crop is not large it is well to gather them in small quantities from the trees, and thus lengthen the season. Many of the mid-season and late kinds have suffered from drought and have fallen badly, but with a good crop this need not be deplored, as the fruit left will be finer. Late kinds may be assisted with liquid manure. By giving a mulch of short manure or by feeding with liquid, the fruit will be finer and more valuable.

G. WYTHES.

## KITCHEN GARDEN.

### CAULIFLOWERS.

Few vegetables require more generous treatment than early Cauliflowers, and the more so is this necessary during a dry season. Why Cauliflowers should fail at these times in some gardens may well be asked. Certainly good, close heads, and these of a delicately white colour, are not often seen. According to my observations there are more early Cauliflower failures now-a-days than in years gone by. It is only of later years that one hears so much of the benefits accruing by deferring sowing till the new year is well in. This, I think, is where the mistake lies; not that the system is really bad in itself, as many gardeners, myself included, have grown good Cauliflowers by the method. The plants are more liable to suffer from checks than can possibly happen by sowing in the autumn and growing them cool throughout. Nor can the plants produce heads fit for use earlier than autumn sown. Instead of there being so much extra care and attention needed to be bestowed upon the autumn-sown plants, I think I can safely say it is just the reverse. As a rule the mistake is generally in sowing too early, pricking the plants out in too loose a compost, and afterwards in coddling them too much. Either or all of these is

sufficient to mar the prospects of any Cauliflowers. Sown too early, and if the autumn should prove to be mild, the plants are bound to become overgrown. With the plants overgrown, the gardener becomes anxious to get them out in the spring before even the weather is suitable for their well-being, and, as any gardener knows perfectly well, checks from inclement weather stop growth, with the result of early buttoning. It is just the same with coddled plants, and pricking the plants out into loose soil in frames is equally injurious. It is useless to plant out Cauliflowers which have been wintered in frames if the soil will not adhere to the roots. Old potting soil is such a favourite medium for many purposes, that the majority of people when writing of Cauliflowers recommend such material for pricking out autumn-sown Cauliflowers. A worse material could hardly be recommended, as such will not hold together when lifted. Of course, if the plants are to be potted up it does not matter so much, but even in these cases the plants will be better by having the compost employed of a more holding description.

As far as my experience and observation of the practice in other gardens go, I find the first week in September quite early enough for seed sowing, and this could be taken as a guide for most districts. Recent notes in THE GARDEN have suggested the most suitable varieties for autumn sowing, these being Early Dwarf Erfurt, Early London, and Walcheren. A variety not often seen recommended is the Large Asiatic. This is an excellent Cauliflower, and also forms a good succession variety to the two former. Earliness is also a point with these autumn raised plants, they being a decided advance over others sown in January, although by some growers these are supposed to have the advantage. To get Cauliflowers as early as possible, the plants must be pricked out under handlights, as with these there is no disturbance and they grow away direct. A few Cauliflowers grown in this way, or as many as handlights could be spared for, would prove most useful in any garden.

The seed should be sown in an open and sunny spot, the soil being light and friable. I select a portion of a south border, also sowing the seeds in shallow drills, and these thinly. Plants raised in this manner have stout stems, and are not liable to be affected with mildew or gangrene, this latter clearing the seedlings off wholesale. By the time the first pair of rough leaves has grown to a fair size the plants will be quite large enough for pricking out. As long as this can be done before the advent of cold weather it will suffice. For pricking out into frames, select a low frame in an open and sunny position, the frame also being set on a hard bottom. This is important, as if the base should be at all loose the plants will root deeply, when of course they will not lift readily in the spring. A firm ash bottom is the best, as the plants move off this material cleanly. Over the bottom place a layer of short rotten manure to the depth of 2 inches, this being levelled down with the back of a fork, and over this the same depth of holding soil with the addition of a little pulverised horse manure. Into this the little plants are pricked out 4 inches apart. At no time must the plants be coddled, severe frosts and heavy rains only being guarded against. For ordinary frosts a couple of mats will be sufficient protection, but in times of severe and prolonged frost the sides must be banked up with stable litter with sufficient on the glass to keep out frost, although a degree or two of this will do no harm. I have kept the plants covered up for a month, and at the end

of this time they have been quite fresh. It is bad practice to uncover the frames daily in times of severe and prolonged frosts. Even if the sun shines brightly in the middle of the day such exposure only excites the plants. After the frost is past gradually expose the plants until it is safe to pull off the lights again daily. The surface soil will also be benefited by being lightly stirred, and if mildew appears dust with wood ashes. The plants will under this treatment grow sturdily, and when large enough the time will be at hand for transplanting, and which, as I have previously advised, must be done carefully, lifting with as large a ball as possible. I cut each plant out in squares with a clean and sharp flat trowel, and they never fail to become well established. The ground can hardly be too rich for Cauliflowers, and in planting it will be found advantageous to draw rather deep drills, into which set the plants, pressing the soil about the balls with the fingers, finishing off with a thorough watering. If the weather should prove dry, of course this will have to be repeated. Planting in drills will enable the water to reach the roots, while another advantage of the drills is that they afford some protection during the earlier stages. Later on, either after a watering or rain, the soil can be pulled round the plants with a hoe.

If the plants are to be potted up use what are termed 48's. After potting, plunge to the rims in a cold frame, treating exactly as for pricked-out plants as regards free ventilation and protection, only care must be taken that at no time, especially in the early spring, must they suffer from want of water. The handlight plants for early cutting must either be accommodated with a south border or an open position well open to the sun. In either case it is best to prepare slightly raised stations for each handlight.

A. YOUNG.

**Sutton's Mammoth White Runner.**—This is a capital Bean, and well worth growing by all who have profit in view. It is rather later coming into bearing than the old Scarlet Runner, but this is rather an advantage than otherwise if sown at the same time. The growth is very vigorous, and the yield of long dark green pods prodigious. Its white flowers also render it attractive in the kitchen garden.—N.

**French Bean Negro Longpod.**—This Bean—if we may judge by the few places in which it is now seen—has fallen into disrepute, yet for all that it is one of the most useful of its class. It has a good constitution, is not so easily affected by cold winds as Canadian Wonder, and is rather earlier in coming into bearing than that variety. Its colour is good and the flavour delicious. I hope this good old Bean will not be allowed to go out of cultivation.—C. H. N.

**Potato Sutton's Seedling as an exhibition kind.**—Amongst all the sorts of second early high-class Potatoes I do not think a better can be found for exhibition than Sutton's Seedling. It matters not whether shown in a collection of vegetables or as a single dish, it always tells if well grown. When speaking of Sutton's Seedling as an exhibition Potato, however, it is but fair to say that for cropping and quality also it has few, if any, equals. Windsor Castle, a Potato somewhat similar in size and shape, is very hard to beat either for showing or eating, while it is a prodigious bearer. It is in season from a fortnight to three weeks later than the Seedling.—C. J.

**Transplanting spring Onions.**—Some time ago a writer in THE GARDEN advised raising the Spanish section of Onions in boxes in heat in spring, and after duly hardening them off, planting out on the open quarters, contending that Onions so treated were not so liable to the attacks

of grub on hot, shallow soils as were those sown in the ordinary way. From what I have this year seen, I am inclined to think that there is much truth in the statement. A neighbour of mine, who for many years had failed to grow either Tripoli or spring-sown Onions, adopted the above-named plan, with the result that at present he has a grand lot of bulbs, which are sound and free from all traces of the maggot. Probably the earliness of the young seedlings enables them to grow beyond the stage at which the maggot usually attacks them. Those troubled with this pest would do well to give the transplanting system a trial, using plenty of soot at digging time.—J. C.

**Early Brussels Sprouts.**—I have never been able to see the advantage of sowing this vegetable so early in the year as some do, especially in the south of England; in fact, I seldom sow the seed till March even for my earliest batch, and then in the open air. I am from this sowing able to pick good sprouts in October, which is in my opinion quite soon enough, as Brussels Sprouts, like many other winter greens, are always much improved by a few frosts. Some gardeners I know sow seed in February in heat, thinking they cannot be too soon. The result is that on good ground the plants by August attain to a great size, and during September coarse open sprouts resembling small Cabbages are produced, and that, too, when there is plenty of more seasonable vegetables in the garden. The fact that in my midland garden good sprouts are obtained by October from March-sown seed is, I think, sufficient proof that very early sowings are quite unnecessary.—H. C.

**Open-air Tomatoes.**—There is no doubt that with our improved summers Tomatoes may again be successfully grown in the open air, even where there are no walls, always provided perfect shelter can be afforded. The other day I saw in the home nursery at Gunton, within four miles of the sea, a splendid lot of plants carrying fine clusters of fruit, some of which were ripening. It is but right to say that the situation is highly favourable, being screened from winds from every point, and the soil warm and well drained. The plants were growing trained to stout stakes on the single rod system, being slightly mulched with short litter, and amongst the several sorts Ladybird was most conspicuous. Mr. Allan considers this variety better than Ham Green. When we consider that Norfolk is not one of the warmest counties, surely in the more southerly ones open-air Tomatoes might be made to pay if the right sorts were chosen and pains taken in their culture. It seems to me that the plants are often unduly exposed in hardening off after coming from a warm, moist house, the foundation of disease thus being laid. Although a sunny position is imperative when planted out, if the same is exposed in the least degree to cutting winds, failure may be expected.—J. C.

**The Potato crop.**—I have under my control just now a dozen diverse trials of Potatoes in Surrey. These trials comprise some seventy sorts, and are in area ranging from 10 rods to 20 rods. Also they are on all sorts of soils, clay, stiff loam, bog, chalk, sand, and combinations. In every case the breadths look wonderfully well. The same may be said of Potatoes in every part of the county: indeed, present appearances indicate an immense crop of tubers later. The earliest and tenderest sorts, now that heavy rains and a lower temperature have come, show evidences of spotting on the leafage—not of the Peronospora, but rather indications that the foliage of these varieties cannot withstand the change to colder weather. So far as all the second early and late sorts are concerned, the top growth is distinctly strong, indeed luxuriant, too much so in fact, especially that in great breadths a second blooming has resulted. In the earlier sorts, where swelling of the tubers was distinctly checked, there is much super-tuberating, but it is not possible to say how far that evil may have extended to the later ones, though it is hoped that it has not. We have had plenty of rain for the Potatoes, indeed too

much, and now badly need warmth and dryness. Generally I regard growth on all main crop varieties, owing to the long drought and now the excessive rainfall, as some two or three weeks later than usual; hence there will be all the more need for a prolonged and dry autumn. If, as is prognosticated, we are to have a considerable spell of this broken, wet, cooler weather, the effect on the crop may presently prove to be most disastrous. Our Potatoes are now at the mercy of the weather. If that be fine and warm, we may have one of the finest crops on record. If it be bad, then the result may be a misfortune.—A. D.

As a rule, except on cool, moist soils, first and second early crops of Potatoes have this year proved indifferent, and I have noticed at several exhibitions how much affected with scab the tubers have been. In my own garden, however, I have not seen a trace of disease until to-day, when I was sorry to find some affected tubers, and that, too, in a so-called disease-resisting variety. The freedom from disease in early and second early Potatoes this summer confirms the opinion I have before expressed, that the germs of the disease may be present, but that it will make no headway unless the weather be favourable to its development. As regards late field Potatoes in this district, the copious rains of the last fortnight came in the nick of time, and with a favourable autumn many confidently hope for an abundant yield. I think Renown will eventually become a very popular late Potato, and will when seed tubers are cheaper be largely grown for market. It is a prodigious cropper, almost as round as a cricket ball, while the flavour when cooked is delicious. It bears some resemblance to Schoolmaster, but resists disease better than that sterling variety.—J. C., *Notts.*

**New Tomatoes.**—Two comparatively new Tomatoes destined, I think, to make a mark are Duke of York and Chemin. Although I have not myself grown either, I have noted their characters in other gardens. A neighbour of mine has grown the Duke for two seasons and thinks very highly of it. Not only has it perfect symmetry, colour, and flavour, but what many of the finer looking Tomatoes lack, good cropping powers. Those who have opportunity for trying new Tomatoes will do well to give Duke of York a trial. Chemin I have only seen in one establishment, but I am much impressed with its general appearance, and should its flavour prove to be as good as its appearance, it will make an ideal lunch Tomato. Ladies generally object to very large fruit for eating in a raw state; hence the necessity for growing at least one medium-sized sort for that purpose. That Chemin is both prolific and early is proved by the fact that it was carrying more fruit than plants of several popular sorts growing in the same house, and that many of these were nearly fit for eating, while those on the other sorts were comparatively green.—C. N.

## ORCHARD AND FRUIT GARDEN.

### RUBUS CAPENSIS.

MR. LUTHER BURBANK, Santa Rosa, California, who sent us the photograph from which the illustration was prepared, in writing to us *re* *Rubus capensis*, says that it came to him by way of New Zealand from South Africa, and is probably the one Stanley speaks of as growing in places on the Dark Continent. The canes grow to a height of from 6 feet to 10 feet, bending over and rooting. The plant is covered with a short rusty down and a few short scattered prickles. The fruit is of a purplish wine or mulberry colour and of excellent quality, though the berries do not separate from the receptacle as freely as they ought.

**Cherry Florence.**—For late use this large, showy dessert Cherry is invaluable. Like other

strong growing kinds, it does not commence bearing so soon as Governor Wood and Black Tartarian, but makes up for lost time in after years. I have a horizontal-trained tree on an east aspect at present bearing a nice lot of large highly-coloured fruit. One of its chief recommendations, in addition to size and high quality, is its long-lasting character, the fruit hanging for weeks in a sound condition if kept from birds.—J. C.

**Planting out forced Strawberries.**—It is an old plan to plant out forced plants of such Strawberries as Keens' Seedling, Viscountess, or indeed any of the early varieties, for furnishing a full crop of ordinary-sized fruit for general use the following year. In this case the runners are kept

fortunately common amongst all early Apples. Of course, the flavour of Juneating is not nearly so good as that of Irish Peach and Beauty of Bath, which ripen soon after it, but where earliness is a desideratum one or two trees as espaliers are certainly worth growing, as with nearly all other dessert Apples Juneating is of much better flavour from espaliers than from bush or standard trees.—J. C.

### MELONS AT HILLSIDE, NEWARK.

A FEW days ago I inspected at Hillside, the residence of Colonel Newton, one of the most meritorious crops of Melons it has ever been my privilege to see. The plants occupied a house having an arched roof and running north and south, and were grown on what may be called the extension system, which has much to recommend it, and from which the largest, if not the best flavoured, crops of Melons are cut. Of course, the restriction system of culture in early houses is imperative, as their small size necessary for securing sufficient heat for the plants at that early date is insufficient for plants that are to be allowed to ramble, but for plants which are to ripen their fruit, say, at the end of July or beginning of August, commend me to a loftier structure and the extension system of growth. The Melons in question were planted on each side of the house, which is about 20 feet long and of good height, sufficient, in fact, to allow of a growth of 8 feet or 9 feet for each plant. The beds contain no hot-water pipes, but are heated by manure and leaves well trodden in and surmounted by a ridge of sound calcareous loam. Plenty of room is allowed between each plant, as close growth in the case of the Hillside plants

*Rubus capensis.* From a photograph sent by Mr. Luther Burbank, Santa Rosa, California.

cut off. Lately, however, it has been found that by planting out some of the more delicately-flavoured and less rampant sorts after forcing, and keeping a few of the runners which these produce pegged down, these latter produce fruit of the first size and quite equal in flavour to that borne on the parent plant. Empress of India is said to do exceedingly well under this treatment.

**Apple White Juneating.**—I have before referred to the usefulness of this little Apple for very early work and of its suitability for training as an espalier. This year again our tree is loaded with fruit, which is very passable for dessert if eaten soon after being gathered. If laid by long it becomes mealy and tasteless, a fault un-

would be ruinous, both the main stems and laterals being exceedingly vigorous and the leaves large and leathery. I was particularly struck with the various stages of growth the Melons were in, plenty of very large fruit being at the top of the trellis, the great strength of the laterals at that point not only enabling the Melons to set, but to swell away, instead of turning yellow and falling off as is frequently the case with the secondary set of fruit on more restricted and less vigorous plants. In houses like the one at Hillside little fire-heat is needed, as it catches the morning sun as soon as it rises and reaps the full benefit of that agent through the afternoon and evening, and by early closing the heat is retained well

into the hours of darkness. Mr. Day, Colonel Newton's gardener, finds these strong plants rather addicted to stem canker if great care is not exercised in watering, but with discretion in this matter and the use of dry lime directly the first trace of it is seen its progress is effectually checked. The varieties grown at Hillside are Royal Favourite, Imperial Green, and Best of All. The first I was much struck with, several of the fruit weighing quite 7 lbs., of a beautiful creamy colour, and closely netted. Imperial Green is a nice oval-shaped fruit of good colour and fine flavour. Best of All I have never seen so good in colour before, and Mr. Day may be congratulated on having such a true strain of this popular Melon, as many inferior ones are in the market. Some years ago Mr. Taylor when at Longleat used to grow that good old Melon, Meredith's Hybrid Cashmere, to perfection on the extension system. J. C.

**A valuable early Plum.**—When at the R.H.S.'s Gardens at Chiswick recently I noticed a Plum superior in every way to Rivers' Early Prolific and quite a fortnight earlier. It is named Early Favourite, and is a seedling, raised at Sawbridgeworth. The fruit is rather more oval than that of Early Prolific, medium sized, purple, juicy, and with a nice flavour. It is, in my opinion, much better for dessert than Early Prolific, being more sugary. Given a warm wall, it is a sure cropper; indeed, it crops too freely, severe thinning being necessary to prevent the tree being injured. It is a freestone. Grown on a south wall, it may be had ripe early in July. The raisers do not recommend it as a variety for growing as a bush.—G. W.

**A Jargonelle Pear tree.**—In THE GARDEN of the 3rd inst. I note your observations in regard to a remarkable Jargonelle Pear tree said to have been planted in the year 1815, and producing at times as many as 2000 Pears. I have a Jargonelle tree in my garden, planted, I believe, in the year 1830, some fifteen years later than the one you mention. It is in the middle of a hedge, is about 25 feet high, takes its chance, for it is never either pruned or manured, and it invariably produces good crops of fruit; as, for instance, in 1893 it produced about 1500 Pears, last year nearly 2000, and I am sure this year it is bearing between 2500 and 3000 Pears. It has been in my possession for over forty years and I have never known it fail. With me this year there are exceptionally heavy crops of Apples and Pears.—C. L., Newport, Mon.

**Morello Cherries on different stocks.**—Cherries are much affected by gumming and canker, and to prevent this it is well to consider how the trees behave in certain soils, and to grow those kinds on the stock least subject to disease. It is very annoying when the trees have attained a fair size to lose a portion of them by canker; indeed at times the whole tree dies, and in many cases what little is left is so unsightly, that it has to be rooted up. Canker is often attributed to the soil being unsuitable. Doubtless such is the case in some places, but I am inclined to attribute some portion of the evil to the stock on which the trees are worked. I do not think the disease is caused by severe weather, as this season Cherries of all kinds have been abundant and good, thus showing that severe cold is not injurious, and my opinion is that, provided the roots are well nourished and there is a good top growth, there will be less disease. I have a great number of these trees in various forms, and of course not all on the same stock. The Mahaleb, I find, is the best stock on poor thin soil and the trees make more surface roots, and though more food in the way of mulching is required, there are much better crops and the trees make a freer growth with less canker and gumming. Those who fail with the Morello in this country would do well to purchase trees on this stock, as in a season like this the growth of the trees is all one could desire.—S. H. B.

## APRICOTS.

THE crop this season in many districts is not all one could desire; indeed, it may be termed under the average. This can doubtless be accounted for in various ways, the principal cause being that last autumn was not the most favourable for ripening the wood. Others doubtless may think the severe weather experienced early in the year may have had something to do with the failure of the crop, but I do not think such is the case, as our trees never looked better than they do now. So far there have been few losses from canker and what bloom there was set freely, and though much later it was strong. The worst losses from canker were last year early in the season before the fruits stoned. This followed a dry, hot summer, leading me to think the trees must at one time have suffered from drought, being on a raised sloping bank and in light porous soil. I admit they set far too heavy a crop. This must weaken the trees, and in future steps will be taken to prevent so many fruits setting. There are few fruit trees that root so near the surface as Apricots, and those who can give a good portion of the border entirely to them will be well repaid. It is surprising how soon the trees make up for loss of time. In April the fruit was quite a month later than usual owing to the protracted frost, but the weather since was most favourable, and I gathered Oullin's Early Peach in the middle of July, only a few days later than usual. The variety named is a sure cropper, and what makes it more valuable is that it is the first to ripen. Large Early is very fine this season, and where most varieties have only an average crop this is bearing very freely, the fruits large and good. There is less canker in this variety than in any other I know, and in places where Apricots do not thrive I would advise giving Large Early a trial. With me Hemskirk is less liable to canker than the Moorpark, and it is certainly a good bearer and the fruit richly flavoured. I fear I must class Moorpark as the worst as regards loss of branches, and though I still have a large tree or two, I do not know how long they will continue, the losses during the past few years having been greater with this than all others combined. Shipley or Blenheim is bearing a fair crop, and as regards ripening closely follows Large Early. The fruits are not large and its value is as a preserving kind, the fruit being juicy and good and the trees not liable to disease. Many prefer it for drying on account of its useful size and good colour. Kaisha or Syrian is likewise a small variety, and useful for the same purpose. I have others, such as Breda, which is good, but it is very small when allowed to crop freely. This is the best kind when grown in favourable situations in bush form, but for early fruit I would prefer Shipley. The same remarks apply to Frogmore Early, a small fruit, and with me inferior to Shipley. Many of the varieties are much better when gathered from the trees a few days before being used, placing them in a cool house. If we have much rain after a long season of drought and the trees are in heavy soil, it is a good plan to throw off the excessive rainfall by spare lights, boards, slates, or corrugated zinc sheeting, this preventing late fruits cracking and ripening the summer growth, the trees also being less liable to gumming and canker the following season.—G. WYTHES.

— The great scarcity of Apricots generally this season may, after all, prove a blessing in disguise; it certainly will where overcropping has been the rule. Generally speaking, Apricot trees flower so abundantly and set such numbers of fruit that gardeners are apt to think after pulling off thousands that they have over-thinned them, when really half as many more might well have been taken off. No other wall fruit is half so long suffering as the Apricot, or capable of bearing the strain of excessive cropping; hence the abuse to which it is subjected. This season, however (the crops in most gardens being very scanty), the trees will be able to recoup themselves where weakly or exhausted, and to make strong shoots and stout buds for the coming year. The roots

should be fed as often and as liberally as possible, bearing in mind that a dry root-run, even to barren trees, is far more prejudicial than a moderate crop with sufficient root moisture. Owing to there being no fruit, trees will be apt to be overlooked this year.—J. C.

## BLENHEIM ORANGE APPLE.

THIS Apple has such a bad character of being an indifferent bearer with some cultivators, that anything that can be truthfully said that will help to disabuse the minds of those who are of the same opinion may be interesting. I write from a district—the vale of Taunton Dene—where there are probably more trees of this Apple grown than in any other part of England. Climate may perhaps have something to do with the behaviour of the trees; whether that is so or not, the healthy condition of the trees and the regularity with which they bear stamp the Blenheim as the most profitable Apple that can be cultivated when plenty of trees is grown to offer an inducement to the grower to find the best market for the fruit. I have said the trees bear regularly; by this I mean they are rarely barren of fruit, but the majority of them bear a heavy crop one year and a light one the next. Strange to say, both last year and this the majority of the trees are producing wonderful crops, some of them having as many as six or seven bags of fruit (120 lbs. to the bag); and as these will always realise 20s. per bag and sometimes 25s., my statement that it is a very profitable Apple to grow is borne out by facts. There is a prevailing opinion abroad that the trees are a long while in coming into bearing; that may be so if they are planted in a poor thin soil. The Blenheim should only be planted in ground that is naturally good and deep. If it is necessary to make the soil for them it will be sure to end in commercial failure, but given a favourable root medium and a climate such as prevails in the south or west of England, the Blenheim Orange comes into bearing as soon as any other sort of equal merit, whether the trees are in the form of standards or large spreading bushes. With regard to the latter form, I have a dozen examples in my garden, planted seven years ago, that have borne regularly ever since the third year, giving large and handsome fruit, that makes me regret the number is not twice as many.

In suitable land there is no better or more prolific sort grown that is so well adapted for re-grafting fairly young trees where it is desirable to change the sorts. There is no more successful grower of the Blenheim Orange Apple than Mr. James Stevens, of South Road, Taunton. Six years ago he had a tree regrafted with this sort, and the second year after grafting, the tree produced two bags of fine fruit. Of course, there was a good number of grafts put on, so that a fine head was formed the first year. Unfortunately, in this part of the country there is more than one variety of the Blenheim, some of them inferior in size and flavour to the type. One cannot be surprised at this, seeing what a favourite the sort is and the many attempts made by amateur cultivators to raise trees from the pips. One frequent cause of failure in planting this sort in standard form is placing the trees too thick; they should stand 40 feet apart each way, and then they will form fine symmetrical heads and prove a source of pride and profit. Some claim for this sort a complete immunity from canker, but my experience and observation do not support that view. In highly manured ground I have seen it canker to such an extent as to completely spoil the trees. It certainly does not canker nearly so much as some other sorts. With me it does not canker at all, while such sorts as Cellini, Warner's King, Stubbard, and Ribston Pippin are badly affected by it. I am inclined to the opinion that rich manure applied to the roots favours the spread of canker.

Taunton.

J. C. CLARKE.

**Profitable Raspberries.**—In the case of many fruits the recently raised varieties have

size, but it is certainly at the expense of quality. This, however, cannot be said of some of the more recently introduced Raspberries. Few, I think, having any knowledge of these would care now to plant such as the old Antwerp or Fastolf even where selling the fruit is intended. Baumforth's Seedling, although not strictly speaking new, is wonderfully productive, and that too in spite of the enormous canes it makes on rich soil. Its constitution also is good, as proved by its standing the terrible frost of February in last year, when Raspberry canes were far from being well ripened, some of the older less robust growers, and which one would suppose were better ripened, succumbing. Good as Baumforth's is, I am not at all certain but that its new rival, Superlative, will in future be more largely planted. The individual fruits are so large, as to put one in mind at a distance of Vicomtesse Strawberries, and the yield is enormous. Those who intend planting Superlative and wish for good canes should order early, as for the next year or two the demand for it will assuredly be great. I have not grown Hornet myself, but hear of its value from various sources. This is being largely planted for market. Northumberland Fillbasket and Carter's Prolific are also two grand additions to the list of profitable Raspberries, and should be added to the previously named sorts where there is room. Where ground is limited it will perhaps be as well to adhere to the first three varieties. Superlative requires to be well ripened before being gathered, otherwise it does not leave the stalk so readily as some. To give these fine Raspberries justice they should not be grown huddled round stakes, but on the post-and-wire system, where every cane can get the full benefit of sun, light and air.—J. C.

#### GUMMING IN PEACH TREES.

I SHALL feel greatly obliged if you can tell me the cause of gumming in young Peach trees and if it can be stopped, as on regulating the wood in a young tree that has grown rather strong, I found the stem had commenced gumming just above where it is worked, and on cutting the bark, I found the under bark very sickly and in a state of decay. Cutting the bark caused the tree to bleed very badly. The variety in question is Waterloo, planted in a house with several other trees. The tree was planted two years this autumn. The house in which the tree is growing is well elevated, and the border is of a strong retentive nature.—H. LEWIS.

\*\* All stone fruit, that is to say, Apricots, Peaches, Nectarines, Cherries, and Plum trees, are more or less liable to be affected by the disease known as gumming. This disease is of a fungoid nature, and classed as *Coryneum Beijerinckii*. It is decidedly infectious, but, comparatively speaking, powerless against the hard wood of a healthy, cleanly grown, perfectly sound tree. Only when wounds are caused either from bruising, neglected ties and shreds, and such like do the spores effect a lodgment in the old bark, though they are equal to penetrating the soft, young wood. In the former case gumming is followed by the loss of branches and whole limbs, and in the course of time the tree succumbs to it. When, however, the young shoots only are affected they may be cut cleanly away and burnt, the rest of the tree not suffering from the disease. It is those trees that are gross in habit—rooting, probably, in a strong, rich, imperfectly drained border—that are most liable to gumming, and in such cases partially or wholly lifting, root-pruning, replanting in fresh and less rich compost, in which lime rubbish and burn-bake are freely used, are good preventive measures. Starvation treatment also favours the spread of this much-to-be-dreaded disease. Any trees, therefore, that are established in a poor worn out border should be lifted next autumn and replanted in a stronger and more durable compost. In all probability the tree alluded to by H. Lewis prior to being under his care had been grown rather strongly in the open ground of a nursery, and

had been further rather hard pruned in order to form a many-branched, fan-shaped tree. Naturally the wood grown in the open is rarely, if ever, so hard and well ripened as that which gets the benefit of the extra heat reflected from a wall, and, according to my experience, hard pruned, immature wood is altogether unsuitable for laying the foundation of a good durable tree. Any way I have found nursery-trained trees more liable to gumming than are those procured as maidens and trained on the place either under glass or against a south wall. At first sight it may appear a somewhat drastic remedy if I advise H. Lewis to clear out his tree at once and burn every particle of it, but if saved the chances are large branches will collapse after flowering next spring, and an unsightly tree be left, while there is also a risk to be run of other trees near at hand taking the disease. The alternative (root pruning) has already been given, and in addition to this the gummed portions must be cut out where possible, dressing with painters' knotting, and also claying over the larger wounds.—W. I.

**Thinning Apples.**—Although the splendid rains have come in good time to help swell the immense crop of Apples we have this year, yet

*Tricuspidaria hexapetala*. Engraved for THE GARDEN from a photograph sent by Lord Annesley, Castlewelan, Co. Down.

there is just as much need as existed before the rains for thinning the fruit. It may be difficult to do this on large standard trees, but, still, were the fruit on the lower branches removed and used or disposed of, that on the upper portions of the tree would be all the finer, and it is only fine, well-finished fruit that will find a profitable market this season. Presently, when gathering becomes very general, there will be a glut of Apples and prices will rule low. It is unfortunate that when we get such grand fruit seasons as the present there should be such flooding of the market, but in the case of such an immense crop as Apples seem everywhere to present there is no help for it, as so few care to store these fruits largely. But apart from market disposal there is to myriads the important one of home consumption, and even in this case the finest fruit affords most satisfaction. I was in a garden a few days since where Apples on stumpy bush trees were most abundant, and the gardener said that he had been thinning out the fruits almost from the moment they were large enough for use. He said also

that where crops on trees had been so thinned, the proportion which fell was relatively small. Of course, the rains have checked further thinning in that direction, but the need for hand-thinning remains all the same. There is no doubt also but that when fruits have thus been well thinned, and those left have opportunities for fuller maturation, they keep so much better. Nurserymen never allow their young trees to be overloaded; hence they get such fine fruits, which keep long and well.—A. D.

## TREES AND SHRUBS.

### TRICUSPIDARIA HEXAPETALA.

THIS lovely flowering shrub from Chili, which is better known as *Crinodendron Hookerianum*, has flowered in the gardens here for several years past, and appears to be quite hardy with us. It is planted in a shady border near a large Yew hedge, and is growing in peat, leaf soil, and loam in equal proportions. It flowers twice a year, in the spring and in autumn, the colour of the flowers being a deep rich crimson.

The plant the photograph was taken from is now carrying sixty flower-buds. Being near the sea we get very little frost in ordinary winters, and the *Crinodendron* requires no protection, but in a less favoured climate it would be well to pot it and winter it in a cool greenhouse. In the same border are growing *Mitraria coccinea*, *Andromedas*, *Eugénias*, *Myrtles*, *Aralias*, and a number of other things supposed to require protection. Since I sent you the list of plants killed by the frost last winter I find the following are not dead and will recover, viz., *Aster argyrophyllus*, *Callistemon coccineus*, *C. spectabilis*, *Carpenteria californica*, *Ceanothus azureus*, *Correa viridis*, *Escalloniamentoides*, *Eucalyptus cordata*, *E. piperita*, and *Eupatorium riparium*. T. RYAN.

**Æsculus parviflora.**—This is now considered to be the true name of that beautiful shrub so long grown in gardens as *Pavia macrostachya*, the genus *Pavia* being now completely absorbed into that of *Æsculus*. Besides this the specific name of *parviflora* scarcely does it justice, for though the individual blooms are rather small, yet collectively they form a fine display, for the long spikes are closely packed with blossoms, which from their protruding stamens cause the inflorescence to acquire a Bottle-brush-like character. The flowering season being, as a rule, from the latter part of July onwards, renders it additionally valuable, for shrubs in bloom at that time are by no means numerous. It needs a spot where the soil is at all times fairly moist, and it will do well in quite stiff loam. This shrub is seen at its best when occupying an isolated position on the lawn, or in some such a spot, for suckers are pushed up in considerable numbers, so that it naturally forms a dense hemispherical mass, clothed with very dark green Horse Chestnut-like leaves, and at this time of the year

studded with spikes of whitish blossoms. A succession of flowers is, as a rule, kept up for a considerable time.—T.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

AUGUST 13.

A MOST noteworthy display was again to be seen at the Drill Hall meeting of this date—remarkable not only from the splendid quality of the exhibits, but also from the excellent variety coming under the inspection of each of the committees. Hardy flowers were an important feature, Lilies on this occasion being strongly *in evidence*, these comprising not only the best of the so-called garden Lilies, but also of the newer varieties of the Water Lilies, a section which must beyond any question rapidly gain in favour judging from the blooms exhibited at this meeting. Of Dahlias, the most beautiful were to be found in the Cactus section. Gladioli were particularly good, and so were the mixed collections of hardy herbaceous flowers. A choice selection of the rarer kinds of exotic Ferns was most interesting and instructive.

Orchids, if not so numerous, were quite up to the usual standard of excellence both in hybrids and species, notably in such of the latter as are none too common, viz., *Vanda cœrulea*, *Saccolabium cœleste*, and *Cypripedium Stonei candidulum*, whilst of the former, the *Lælias* and *Cattleyas* held the sway. Fruit was altogether excellent and comprehensive in character, from Grapes to Strawberries, the splendid quality of the Apples betokening a rich harvest later on of well-developed fruit. Of Melons, Cherries (late dessert) and Plums there were good exhibits.

#### Orchid Committee.

First-class certificates were awarded to the following:—

**ODONTOGLOSSUM WATTIANUM** (figured in THE GARDEN, May 3, 1890, p. 416).—A decidedly distinct and most beautiful variety, of free, vigorous growth, the one spike bearing fourteen fine flowers and buds; the lip, which is most distinct, is elongated in shape, with a large heart-shaped central blotch of rosy purple and numerous spots of the same colour on a creamy white ground, the sepals being barred with pale chocolate and the petals spotted sparsely with the same colour, both on an old gold-coloured ground. From Messrs. Sander and Co., St. Albans.

**CATLEYA EROS** (*C. Walkeriana* × *C. Mossiae*).—A singularly fine and very distinct hybrid, in which the influence of each parent was about equal, the sepals and petals having the most pleasing soft shade of rose to be seen in the best forms of *C. Mossiae*, with the flowers equal in size to those of that species. *C. Walkeriana* was evident in the form of the lip and the general contour of the flower, being quite expanded to the base, thus leaving the column quite open to view, the colour here being a rosy purple, darker at the extremity of the lip, with slight touches of a deep golden tint. From Messrs. Veitch and Sons, Chelsea.

**CATLEYA FOWLERI** (*Cattleya Leopoldi* (?) × *C. Hardyana*).—A very richly-coloured hybrid having the peculiar shading in the sepals and petals of the best forms of *Lælia elegans*, with the same shape also and growth, the lustrous sheen suffusing the magenta shade being most marked. The lip is broad and well expanded, being of a very deep purplish magenta, with an undulated margin which showed to good effect; in every respect a choice and distinct hybrid. From Mr. Gurney Fowler, South Woodford, Essex.

**VANDA CÆRULEA** (Fowler's variety).—This was undoubtedly the feature of the meeting amongst Orchids, well deserving the award given to it. Either a medal or a cultural commendation might well have been given in addition. The superiority of this form was most apparent to even a casual observer; the size of the individual

blooms ( $4\frac{1}{2}$  inches across), the robust spikes with as many as ten flowers in two instances, and the deep shade of cœrulean blue with a lighter marbling made this a most unique exhibit. The plant bore in all four spikes, the growth being most vigorous. From Mr. Gurney Fowler.

**VANDA CÆRULEA**, of which a cut example was shown, a grand spike of fourteen blooms, scarcely so large as the last named, but with the petals distinctly wider, the colour in this instance being also paler, a very fine variety. From Mr. E. H. Woodall.

**CYPRIPEDIUM MASSALIANUM SUPERBUM** (*C. superciliare* × *C. Rothschildianum*).—An exceedingly fine hybrid and very distinct, the dorsal sepal large and well marked, as in the latter parent, the petals, on the other hand, quite broad as well as of considerable length, assuming a drooping form, and densely spotted with dark maroon spots on a light ground. The lip is elongated and of a bronzy purple tint; one plant bore three flowers to the spike. From Mr. Statter and Messrs. Sander and Co.

**DENDROBIUM PHALÉNOPSIS HOLOLEUCUM**.—A lovely form of this very variable Orchid, with milky white flowers of fine shape, very distinct, the growth being apparently less vigorous. From Mr. J. F. Holmes, Bath.

Awards of merit were adjudged to the following:—

**CATLEYA LEOPOLDI** (Sander's var.), which beyond any question must be classed as the finest of this fine species, the colouring, which was greatly intensified both in the ground colour and the spotting, was a notable feature, but in the case of the lip it was even more marked still, being of an intensely deep crimson-purple, the spike also a very fine one. From Messrs. Sander and Co.

**ODONTOGLOSSUM HARRYANUM** (Haywood's var.), which is best described as a major form of this fine and distinct species; the colour much deeper, the sepals and petals being of a very dark chocolate with pale green veins, the lip at the same time being of greater length, the blotch of golden yellow on its centre likewise of a richer shade, a very vigorous example. From Mr. Haywood, Woodhatch Lodge, Reigate.

**MAXILLARIA PURCATA**.—A singularly fine and distinct species in every respect, the flowers borne well above the foliage, the colour being a most pleasing harmony of light and dark orange tints, shading off to white at the base of the sepals and petals. From Sir Trevor Lawrence.

**LÆLIA MONOPHYLLA**.—(Quite a miniature species, the flowers, which are produced singly, being each about  $1\frac{1}{2}$  inches in width and of a deep shade of orange-scarlet. This small, but pretty species was introduced from Jamaica in 1883. From Sir Trevor Lawrence.

**LÆLIO-CATLEYA ELSTEAD GEM** (*Cattleya bicolor* × *Lælia xanthina*).—A most distinct and noteworthy hybrid, having a combination of colour not yet seen in any other of its race; the sepals and petals are of a clear golden yellow as in the last-named parent, being about  $3\frac{1}{2}$  inches across, the lip being of a clouded purple tint, a marked contrast to the other parts of the flower. From Mr. Ingram, Elstead House, Godalming.

Botanical certificates were awarded to *Eria stellata*, a very pleasing variety with star-like flowers of a rosy shade, the spikes being of considerable length and densely packed. From Admiral Cator. *Polycynis Lehmanni*, a beautifully marked species with small graceful flowers, not unlike *P. lepida*; *Polytachya odorata*, with small greenish yellow blossoms in dense spikes, and *Dendrobium longicornum*, with rather large white flowers, the lip marked with lines of orange-yellow. All from Sir T. Lawrence.

Mr. Haywood, Woodhatch Lodge, Reigate (gardener, Mr. Salter), had a splendid group of *Odontoglossum Harryanum*, consisting of forty plants, all in the most luxuriant health, bearing unusually fine spikes and comprising several superior forms, one of which has been already noticed; some of these plants bore spikes with as many as eight flowers to each, the colour in every

instance being excellent. A finer lot of this very distinct *Odontoglossum* has never been staged at any previous meeting, whilst the tasteful mode of grouping was most commendable. With these were a few good plants of *O. vexillarium*, the whole being set up with Maiden-hair Ferns and light Palms (silver Flora medal). Another of these unique exhibits of cut Orchids came from Baron Schröder's collection (gardener, Mr. Ballantine). The varieties were of the very finest description, whilst the cultural condition was quite equal. Of *Aerides Lawrenceanum Sanderianum* there was a grand spike, bearing very large flowers (this is one of the finest *Aerides* in cultivation); *A. nobile* was also shown; this is a glorified *A. odoratum*. *Sobralia Lowi*, with deep purplish mauve flowers, a very distinct species, and *Mormodes luxatum*, an immense spike densely covered with its singular creamy white flowers of wax-like substance, were shown, each in fine character. Of *Vandas* there were lovely examples of *V. insignis* (true), its lustrous brown sepals and petals and expanded rosy lilac lip, rendering it quite distinct from *V. tricolor*, with which it was at one time confounded. *V. tricolor* in one of its finest forms with dark sepals and petals was also shown, and so was a charming example of *V. Roxburghi*, a species at one time quite common, but now very rarely seen. *Odontoglossums* were represented by a very large and much-branched spike of *O. ramosissimum* and of singular purity. Of *Saccolabiums* there were *S. Blumei majus*, a long dense spike, and *S. cœleste*, of singular beauty, the rich deep hue of the lip being unusually fine. *Cypripedium Stonei platytanum* was represented by one cut spike bearing three grand blooms, deep in colour, and of *Cattleyas* there was a splendid example of *C. Hardyana* (Clark's var.), which has more of the orange colouring upon the lip, surrounded by the richest crimson-purple. The only plant shown was one of *Cattleya Kienastiana*, the variety a very superior one (silver Banksian medal).

From Sir Trevor Lawrence, Burford Lodge (gardener, Mr. White), came another of his characteristic exhibits, consisting chiefly of species quite out of the common. Two of the most noteworthy on this occasion were those to which awards of merit were given; others comprised *Calanthe natalensis*, a pale sky-blue variety somewhat after *C. masuca*. *Vanda Hookeri*, a truly handsome and distinct species of the Rush-leaved section, was also shown, the flowers very large, with much of the colouring of *Dendrobium McCarthiae*, a deep rosy lilac on a lighter ground. *Miltonia Schröderiana*, a distinct-looking species, was also included, also two very fine spikes of *Phalænopsis Esmeralda*, the one representing the type, having rose-coloured flowers, the other being white, save a very light flush of the same tint. *Aerides Lawrenceanum Sanderianum* was also shown here in equally fine condition. A very singular species of *Oncidium* was present in *O. spileopterum*, very distinct, with a prominent yellow lip. The choice old hybrid *Lælio-Cattleya exoniensis* was also shown well, and a hybrid *Cypripedium* of much promise was asked to be shown again. Of *Vanda cœrulea* there was here staged an immense mass bearing no less than eighteen spikes, producing a fine effect, a cultural commendation being specially awarded, and a silver Banksian medal to the group. Another most noteworthy group was staged from the collection of Mr. Gurney Fowler, South Woodford, Essex (gardener, Mr. Davis); this comprised a fine hybrid *Cattleya* already noted and the grand example of *Vanda cœrulea*, besides which there were *Lælia elegans*, a very fine spike with ten richly coloured flowers; *Catasetum Bungei*, an extra fine example of this singular Orchid; *Cattleya crispata* with the purest of white sepals and petals; *C. Hardyana* of deep colour, *C. Schofieldiana*, *Zygopetalum rostratum*, as well as *Cypripedium superbiens* (Demidoff's var.), a paler form than the type (silver Banksian medal).

From Messrs. Sander and Co. came a very showy group of choice kinds, which comprised a finely-flowered lot of *Dendrobium Phalænopsis* Schre-

derianum, some of which had the imported bulbs of unusual length; one of these bore a spike of remarkable length. *Odontoglossum vexillarium* rubescens, rich rose colour, very distinct, and *Masdevallia Veitchi grandiflora* were both excellent; so also was a grand form of *Cattleya aurea*, the lip being specially rich in its tint. *C. Kienastiana* was also good here, and so was that very distinct *Cattleya Prince of Wales*, which has the form of *C. intermedia*, with the sepals and petals of the softest blush and the lip pale crimson-purple, a lovely variety. *C. Gaskelliana* and *C. Leopoldi* were both shown, including a very fine form of the latter, already noted, as well as a fine new hybrid *Slipper*, *C. Massaianum superbum*. *C. Ida Brandt* (another seedling) was shown well. *Odontoglossum biconense album*, with the lip of pure white; and *Calanthe Laucheana*, with pale purplish flowers, quite distinct; also *Miltonia Clowesi* were all to be seen here, so also were *Catasetum fimbriatum*, a pale, but beautiful species, and *Laelia elegans prasiata*, with pale sepals and petals, the lip on the other hand being of a deep purplish crimson, thus affording a marked contrast. *Cirrhopetalum picturatum* was also shown (silver Banksian medal). Other exhibits comprised a small group from Messrs. Low and Co., which included *Saccolabium coleste*, three plants being shown, one of which was a superior variety with a darker lip and finer spikes; *Cattleya Wallisi*, with pure sepals and petals, the former pointed and narrow, the latter broad and obtuse, and the lip with a rich orange blotch—a very fine white *Cattleya*. *Cypripedium Charlesworthi* and *C. Parishii* were both shown here. From Messrs. B. S. Williams and Son came a group of *Cypripediums*, which included of the choicer hybrids, *C. Morganii*, *C. oenanthem*, *C. G. H. Rogers*, *C. Harrisonium superbum* and *C. Ashburtonæ expansum*, each in good character, also *C. tonsum*, a singularly beautiful species and a fine variety. From Mr. Lutwyche, Beckenham, came cut spikes of *Odontoglossum crispum* and *O. Pescatorei*, both being very good, considering the lateness of the season. *Cypripedium Godefroya*, a near relative of *C. bellatulum* was shown here in two distinct forms, as well as a well flowered plant of *Promenæa stapelioides*. Mr. Hardy on this occasion sent from Tyntesfield a distinct form of *Cattleya crispæ*, with blush sepals and petals, and the lip marked with deep lilac; *C. Brymeriana* came from the same source. Messrs. Heath and Sons, Cheltenham, had a small group of *Dendrobium Phalaenopsis Schroederianum* showing a wide range of colour, the growth being dwarf; *Cypripedium pendulum*, with long drooping petals, and a form of *C. Fairrieianum* came from the same firm. Mr. Ingram had, besides the certificated *Cattleya*, a hybrid *Cypripedium*—*C. album* (*C. leucochilum* × *C. Schlumi*)—which is of a pearly white colour with age, being the nearest approach to a pure white yet seen. From the Botanic Gardens, Glasnevin, was sent a bloom of *Cattleya granulosa grandiflora*, its size its distinctive feature.

#### Floral Committee.

First class certificates were granted to the following:—

**ANTHURIUM MARLE.**—This variety is characterised by a robust and dwarf habit. It has large handsome leaves and a fine pure white spathe which contrasts well with the red spadix. It was raised at Burford Lodge and shown by Mr. Bain, gardener to Sir Trevor Lawrence.

**BRUNSVIGIA JOSEPHINE.**—This is a Cape bulbous plant, the plant shown having an erect scape terminated by a large spreading head of deep crimson flowers. It came from Mr. Low, gardener to Earl Brownlow, Berkhamsted.

Awards of merit were granted to the following:—

**CHRYSANTHEMUM PRINCESS MAY.**—This is a very fine form of the well-known annual *Chrysanthemum* or Crown Daisy of gardens. Its flowers are very large and broad in the petal, white, with a sulphur-yellow zone at the base of the

petals and having a rich yellow disc. From Mr. H. Brownhill, Sale, Cheshire.

**CHRYSANTHEMUM ELEGANS.**—Another charming variety, but rather too much like the preceding one, being chiefly distinguished by its bronzy-yellow disc. Also from Mr. Brownhill.

**CHRYSANTHEMUM SUNSHINE.**—This has flowers of a deep rich yellow colour, the petals broad and overlapping, and the flower almost circular in form. From Mr. Brownhill.

**CHRYSANTHEMUM CHIEFTAIN.**—This also is of a rich yellow colour, but the disc or centre is distinct, of a dark purple hue. From Mr. Brownhill.

**DENDROCALAMUS MEMBRANACEUS.**—A Burmese Bamboo, with distinct merits, like an *Arundinaria* in habit. Its leaves are of a light green colour, each about 6 inches long and 1 inch broad, with a pronounced ring of hairs at the base of each. It was shown by Mr. A. B. Freeman-Mitford, of Batsford Park, Moreton-in-Marsh.

**DAHLIA ARTHUR CHEAL.**—A Cactus-flowered variety of the best form, and of a rich glowing crimson colour. It was shown by Messrs. J. Cheal and Sons, Crawley.

**DAHLIA MRS. A. BECK.**—This also belongs to the Cactus section, its petals extra narrow and pointed, the colour a soft shade of orange-scarlet. From Mr. T. S. Ware, Tottenham.

**GLADIOLUS DUKE OF DEVONSHIRE.**—This is a beautiful variety, with flowers of a light scarlet colour, suffused with white in the throat. Shown by Messrs. J. Kelway and Sons, Langport.

**GLADIOLUS EARL CADOGAN.**—A noble variety, with immense flowers that are practically self-coloured, being of a clear cerise-red hue. We should like to see more of such as this in preference to the splashed and feathered vari-coloured varieties, of which there are too many. From Messrs. Kelway.

**GLADIOLUS DON JOSÉ.**—This is a most distinct break away in colour, and there is nothing at all like it. Its flowers are of a deep rich purple tint, very striking in contrast with that of other kinds. This also came from Messrs. Kelway.

**GLADIOLUS MRS. H. BEECHER.**—This is one of the *G. Childsi* hybrids and a very fine variety with rich crimson flowers, which are shaded and spotted with white in the throat. It was shown by Mr. Bain, gardener to Sir Trevor Lawrence.

**MONTBRETIA SOLEIL COUCHANT.**—A lovely yellow variety as rich in colour as the name would imply. This was also shown by Mr. Bain.

**SORBUS AUCUPARIA FRUCTU LUTEO.**—This, judging from the well-berried clusters shown, is a counterpart of the Mountain Ash except in the colour of its bold clusters of berries, which are of a deep yellow tint. It was shown by Messrs. G. Bunyard & Co., Maidstone.

**TIGRIDIA GRANDIFLORA IMMACULATA.**—A lovely form of the gorgeous Tiger Flower, its large blossoms being pure white, the edges of the inner segments margined with a creamy tint, but free from the spots and showy markings that characterise most Tiger Flowers. Shown by Messrs. R. Wallace and Co., of Colchester.

**TIGRIDIA GRANDIFLORA AUREA.**—The flowers of this striking variety are deep orange-yellow, the base and lower half of the flower profusely blotched with crimson. From Messrs. R. Wallace and Co.

Among the trade groups one of the most noteworthy and certainly the most graceful was a grand group of Ferns from Mr. H. B. May, of Edmonton, comprising all the choicest varieties, arranged in his usual charming way and well deserving the silver-gilt Flora medal awarded. Pterises were well represented by large plants of the new *P. cretica* Wimsett and many other varieties, *P. serrulata* in many forms, and *P. tremula elegans*, having long tasselled fronds. Among *Aspleniums* the following were noted: *A. caudatum*, which has long drooping fronds more than a yard in length; *A. lucidum*, with large pinnules of a polished green; *A. Baptisti* and *A. dissectum*. *Adiantums* were present in great variety, also *Davallias*, *Gymnogrammas*, and little gems such as the *Cheilanthes* and *Nothochlanas*. At the back of the group were

remarkably well-grown specimens of a large size of the following: *Doryopteris*, *Lomarias*, *Platyceriums*, *Acrostichum aureum*, *Microlepia hirta cristata*, *Nephrolepis* in variety, and *Polypodium iridoides*. A charming display of cut flowers was made by Mr. Bain, gardener to Sir Trevor Lawrence, who showed *Gladioli* in fine variety, including many of the handsome *G. Childsi* and *G. Lemoinei* hybrids, and several of M. Lemoine's new and beautiful *Montbretias*. A silver Flora medal was awarded this group. Messrs. Kelway and Sons received a silver-gilt Banksian medal for one of their noble displays of *Gladioli*, containing many fine kinds, amongst which besides those previously mentioned we noted *C. T. Ritchie*, brilliant scarlet with white throat; *Col. Welby*, rich salmon; *R. Morrow*, light rose; and *Lord George Hamilton*, cerise-red, shaded with crimson. *Gaillardias*, the Japanese Wineberry (*Rubus phoenicolasius*) in fruit, and *Dahlia Duke of York*, a single crimson variety with fringed petals, were also well shown in quantity. Messrs. Wallace, of Colchester, were again well represented by *Lilies* in season, especially good being *L. auratum platyphyllum virginalis*, *L. Henryi* and *L. Lowi*, the new and beautiful Burmese Lily. The large-flowered *Gladioli* were well shown in some of the best kinds, and *Tigridias* in the front of this group were strikingly attractive. A silver Banksian medal was awarded. A similar award was granted to Mr. T. S. Ware for a large group of hardy flowers in season, such as *Lilies*, *Phloxes* and *Veronicas*, with single and pompon *Dahlias*. Messrs. Barr and Son had a fine group of hardy flowers, in which were well-grown *Phloxes*, whilst *Lilium tigrinum splendens* and *L. tigrinum Fortunei* (the double-flowered Tiger Lily) were prominent features in the group. A bronze Banksian medal was granted. Mr. W. Robinson received a similar award for *Nymphaea Marliacea albida* and *N. M. carnea*, grand flowers of both these noble varieties being shown, and they attracted much notice.

Messrs. J. Laing and Sons, of Forest Hill, showed a fine group of *Crotons*, young plants in variety, of good colour, and of a useful decorative size. A silver Banksian medal was awarded. *Dahlias* in quantity made their first appearance this season, Mr. J. Walker, of Thame, receiving a silver Banksian medal for a large exhibit of show, Cactus and decorative varieties. Mr. Mortimer, of Farnham, showed *Cactus Dahlias* largely, and was awarded a bronze Banksian medal, whilst Messrs. J. Cheal and Sons, of Crawley, had a group of the best kinds, including several new ones of promise, that will doubtless be seen again before the season is past. A group of *Bamboos* and *Lilies* which go well together came from Mr. McArthur, of Maida Vale, who received a silver Banksian medal. Messrs. B. S. Williams and Son showed plants of *Ixora Duffi* carrying large trusses of bloom, and Mr. Douglas showed a yellow self *Carnation* named *Britannia*. Sweet Pea *Cupid* was again shown, and from Messrs. J. Veitch and Sons, Chelsea, came an interesting hybrid *Begonia* named *acerifolia*, on account of its pointed leaf lobes, which in some degree resemble those of a Maple leaf. They are of a dark olive-green, with light green veins and mottled with silvery white. The Crown Daisies from Mr. Brownhill, of Sale, were a charming feature of the meeting, as he showed them in large quantity, whilst their merit may be gauged by the fact that four out of the seven varieties received an award of merit. Mr. Witty showed a group of pot plants of a *Fuschia* named *Pride of South London*. It has prettily variegated leaves and a single purple and red flower. Mrs. Tudway, The Cedars, Wells, sent plants and cut flowers of a sweet-scented *Carnation* named Mrs. Tudway, but it is a poor kind quite unworthy of a name. *Lobelia cardinalis Crawfordensis*, shown by Mr. Slogrove, Gatton Gardens, Reigate, is a travesty on the brilliant Cardinal Flower, as we do not want a white blotched form like this. Mr. Burt, Caen Wood Towers, Highgate, sent a red striped form of *Lilium auratum*, which, however, does not materially differ from that known as *L. a. rubro-*

vittatum. An erect growing variety of Lawson's Cypress, a purple-leaved Spurge Laurel and Asparagus Sprengeri, a distinct variety, were shown by Messrs. T. Cripps and Sons, of Tunbridge Wells.

#### Fruit Committee.

The exhibits before this committee were numerous, the fruit staged being of excellent quality. There were several new seedling Apples and Grapes.

First-class certificates were given to—

**CHERRY GEANT DE HEDELINGEN.**—A very black large fruit somewhat after Black Tartarian, but later, with firm flesh of delicious flavour. From Messrs. Rivers and Son, Sawbridgeworth.

**PLUM RIVERS' EARLY FAVOURITE.**—This was recently noticed by the committee at Chiswick bearing a very heavy crop. It was sent out by Messrs. Rivers many years ago, having been raised at Sawbridgeworth. The fruits are more oval than those of Early Prolific and very sweet and juicy. It is a freestone and of medium size.

The following Lettuces, after trial at Chiswick, received awards of merit:—

**ROMAINE GRISE MONACHIERE.**—A very fine type of Cos, leaves deep green, heart firm, and of good flavour. From Messrs. Benary, Erfurt.

**ROMAINE BALLON COS.**—A very large variety, and similar to Veitch's Superb White Cos. This variety is remarkable for its sweet flavour and immense size. Messrs. Benary.

**LETTUCE SATISFACTION.**—A Cabbage variety of medium size with compact heart; a good summer Lettuce. Messrs. Benary.

**LETTUCE GROSSE BRUNE TETUE.**—A copper-coloured variety noted for its firm heart, good flavour and good qualities in poor soils. From Messrs. Vilmorin.

**LETTUCE MERVEILLE DES QUATRE SAISONS.**—Almost identical in colour with the last, but larger and of excellent quality, the leaves being more fringed. Messrs. Vilmorin.

**LETTUCE ROYAL MALTA.**—A large pale green variety, much curled, similar to the old Malta type, but more compact. Messrs. Harrison and Sons, Leicester.

**LETTUCE ICELEAF.**—A new curled type somewhat like Drumhead, but more compact, the edges of the leaves fringed, heart firm and compact, a good summer variety. From Messrs. Veitch and Sons, Chelsea.

**BUTTER BEAN GOLDEN BEURRE DORE NAINE.**—A fine variety of this section, very free-bearing. Messrs. Vilmorin.

**FRENCH BEAN LONGFELLOW.**—An excellent type, an immense cropper, pods long, with very little stalk, and of good flavour. Messrs. Henderson, New York.

**FRENCH BEAN KING OF THE GREENS.**—A very dwarf grower, very green, roundish pods of good flavour, a free cropper and a very early variety. Messrs. Vilmorin.

**FRENCH BEAN DWARF EARLY MANGETOUT.**—This has long, slender pods of good quality. Messrs. Vilmorin.

**BUTTER BEAN FLAGEOLET ROI DES VERTS.**—A yellow kind of very fine quality, good cropper, pods large and handsome. Messrs. Vilmorin.

**MELON HERO OF MIDDLESEX.**—A seedling between Hero of Isleworth and Syon House; flesh green, of excellent quality and great depth, flavour rich. The fruit is roundish and densely netted. From Mr. G. Wythes, Syon House, Brentford.

**APPLE WHITE TRANSPARENT.**—The fruits are above medium size and have a firm flesh, which is of a brisk acid flavour. From Messrs. Bunyard, laidstone.

**STRAWBERRY (ALPINE) ROUGE AMELIORE.**—Much larger than the usual alpine, long oval fruits, of rich crimson colour, delicious flavour and freely reduced. From Mr. Hudson, Gunnersbury house, Acton.

Messrs. Veitch, Chelsea, staged a very good collection of Apples, Pears, Plums and Cherries, with a few late Raspberries. Beauty of Bath, Duke of Orleans, Early Strawberry, Red Astralian (finely coloured), and Peter the Great Apples

were very fine. The best Plums were Hunt's Early Prolific, Gisborne's, Early Transparent Gage Early Orleans and The Czar (silver Knightian medal). Messrs. Bunyard, Maidstone, had three dozen dishes of remarkably fine Apples, large, well coloured and of good quality, the dishes of Williams' Favourite, Cardinal, Beauty of Bath, Lady Sudeley, Irish Peach, Kerry Pippin, The Vicar, Mr. Gladstone, Sugar Loaf, a very handsome fruit, The Queen and Duchess of Oldenburg being noteworthy (silver Knightian medal). Messrs. Rivers, Sawbridgeworth, had a notable collection consisting of Cherries, Plums, Apples and Pears. Among the Cherries, Emperor Francis, Bigarreau Noir de Guben and Monstreuse de Mesel were very fine. Plums, both from under glass and open air, were remarkable for size and colour. Beacon and Beurré Gifford among the Pears, and Early Rivers, Keswick, Duchess of Oldenburg, Early Julien, and Early Harvester among the Apples were good (silver Knightian medal). Mr. Empson, Amphill House, staged a collection of fruit, consisting of Muscat of Alexandria, Black Hamburg and Madresfield Court Grapes, several bunches of a new Grape, a seedling from Madresfield Court and Gros Colman, Apricots, Peaches, Plums, Apples, and Pears (silver Banksian medal). From the society's gardens came an excellent collection of Plums, the varieties most noticeable being Heron, Late Prolific, Reine Claude de Comte, Early Transparent Gage, McLaughlin's Gage, Golden Esperone, Bittern, Curlew, and Sultan. Mr. Taylor, Oatlands Park Gardens, Weybridge, received a cultural award for a very fine lot of well-coloured Princess of Wales Peaches. Mr. Maher, Yattendon Court, Newbury, sent a new white-fleshed Peach named Epicure, but over-ripe. Messrs. Laxton, Bedford, and Mr. Cleaver, Leamington, sent seedling Apples. Mr. Webster, Beckenham, sent very fine bunches of La Versailles Currant and growths of Raspberries fruiting on the new wood of this season. Mr. Hudson sent two Melons, Sutton's Scarlet and Sutton's Scarlet Hero of Lockinge. Mr. J. Barker, Highgate, had a dwarf Broad Bean, and boxes of Plums packed for market came from Mr. J. W. Aytou, Hereford, to show packing. Messrs. Veitch and Sons staged a fine lot of their new Giant White Cos Lettuce grown in pots. This was considered to be identical with Ballon referred to above.

The lecture on hardy Bamboos was given by Mr. A. B. Freeman-Mitford, who has planted in his garden a complete collection of all the known hardy kinds. He remarked that after a winter of great severity, which had absolutely killed large numbers of reputed hardy trees and shrubs, he was able to report that not one Bamboo in his large collection had perished. Some had been cut down to the ground, but even these had already sent up fresh culms. He regarded hardy Bamboos as a new source or element of exceeding grace and beauty, and pronounced them capable of withstanding the severest cold of our average midland climate. In their native land the season of Bamboo growth was a time of great heat, accompanied by an abundant rainfall, and in proportion as these conditions obtained in our country the more favourable they were to their growth. Early growth, so as to allow ample time for ripening, was the thing to encourage, as the plants needed ripening underground as well as above. In proof of this mention was made of *Phyllostachys mitis*, which always sends up its new culms near to the old ones, the reason for which was not that the rhizomes did not travel like those of other kinds, but because they were imperfectly ripened and consequently died back considerably. It was a great mistake to try and adapt Bamboo planting to the usual planting season in gardens when growth was dormant, and the evils of this course were even yet manifest in the present state of the first lot of plants he planted which came late in autumn and were at once put out in their permanent positions. The right course to pursue with plants received at this period is to soak the roots

for twelve hours, placing the plants in a cool house for the winter, giving little water at the root, but using the syringe freely upon the leaves, and then, although they might shed most of their leaves, others would appear in March and not a plant would be lost. By the middle of May hardening off might begin, and in June the plants should be planted in the permanent positions. When planting, there should be no trampling of the soil to make the plants firm, as great damage might be done to the underground stems. Abundance of water would settle them firmly. He passed briefly in review and mentioned the chief characteristics of all the forty-two kinds growing with him, suggesting that some of the dwarf sorts might become admirable covert and carpet plants in our woodlands, just as they absolutely monopolise enormous areas of woodland in Japan. It has been suggested, and he thought truly, that the reason why so many Japanese plants were of a climbing habit was that this form of growth became a necessity of their existence, otherwise they would be exterminated in the wide-spreading thickets of these dwarf Bamboos. The taller kinds were garden plants of the highest beauty if planted in suitable situations and associations, a background of Holly being the best to show up their graceful charms. Having regard to the growing popularity of these plants, it was most desirable that we should all endeavour to clear up the confusion that still existed as to the nomenclature of the few kinds obtainable in this country, and further that nurserymen should add to their now very limited collections, as at present few indeed of the sorts enumerated were obtainable in our country.

#### MR. A. F. BARRON.

We hear much of dissatisfaction at the recent action of the Royal Horticultural Society as regards what appears to amount to a dismissal of their excellent superintendent, Mr. Barron, who for about forty years has been connected with their gardens, and for the last thirty years has had their entire care, and for many years the management of the R.H.S. shows, and who of all connected with the society has best deserved the confidence of all interested in the society and its work.

The facts of the case are imperfectly known to us, but we hope that nothing done by such an honourable society requires to be done in the dark. The facts should be published so that the Fellows may judge of the wisdom of the course that has been pursued. There is a garden committee, and it has leaked out that instead of consulting with them, as should have been done, the council went outside that body, and employed gardeners from private places to report, or at least sign a report, as to the state of Chiswick Gardens, which are maintained for quite different objects to those of private gardens. This was an extraordinary proceeding, and the more so as it was done without the knowledge of the garden committee. We hope some members of the council will tell us the facts in full about the matter. It would not be possible in England to get a man of such experience in the work of the society as Mr. Barron, and with so many good qualities for the post of superintendent of their gardens. To send gardeners from private places to report on the work in a purely experimental garden shorn of its means and even space of recent years was surely a most unwise proceeding.

Is what has occurred really the work of the council, or of someone who makes a tool of it for his own ends?

— Mr. Barron's retirement has come to all true gardeners as a surprise. Those of us who have visited Chiswick for business or pleasure could not fail to find the latter, as well as unlimited instruction, in the presence of Mr. A. F. Barron.

He was equally at home among fruit of all sorts, out-of-door and under-glass hardy trees and shrubs, flowers and vegetables, and since the renaissance of Chiswick—which may be said to have originated with the life-work of Mr. Barron—it has been impossible to visit the gardens at any time or season without finding hosts of representative plants, flowers and fruits of absorbing interest.

Chiswick, with all its financial and other difficulties, is still the only representative we have of a great national school of horticulture in which something like justice has been done to the culture of fruit and vegetables as well as hardy herbaceous plants and flowers. None who know Mr. Barron—and nearly all gardeners know him—but will reciprocate all the kind words and wishes so ably and well expressed in last week's GARDEN by F. W. Burbidge on page 112. While feeling it a personal pleasure and privilege to wish the retiring superintendent godspeed and a happy and quiet period of comparative rest after so long and honourable a career, and ready to contribute to a testimonial for what the poet craved, "a small house and a large garden," or otherwise, a good many of us marvel greatly at Mr. Barron's retirement in the prime of life and the maturity of his knowledge. For a great many years the wisdom of Mr. Barron, as the administrator of a most difficult trust, was unequalled by his skill as a cultivator, and I say fearlessly, with Mr. Burbidge, that no one alive to-day possesses such a full and accurate knowledge of hardy garden fruits and fruit trees as does the subject of this notice, and so far, even if no further, his retirement from Chiswick will be a loss. Great secrecy has perhaps properly been maintained as to the cause of it. It appears as if the council had taken the initiative in the matter, and if not, of course they could have refused to accept the resignation. To smoothe the matter over with a pension does not satisfy the public, nor serve the highest interests of the society. Possibly enough Mr. Barron desires the rest that he has so well and honourably earned, but he is still in the prime of life and in the mellow strength of his matured manhood and ripened experience, and as capable as he ever was of rendering the most unique and distinguished services to the society that he has so long and honourably served.—D. T. FISHER.

## NOTES OF THE WEEK.

**Polypodium iridoidea** is a distinct and handsome Fern, of which a good plant was shown in Mr. May's group at the Drill Hall on Tuesday. Its fronds, as the name suggests, resemble the leaves of a Flag Iris. They are entire, stand erect to a height of 3 feet or more, taper to a point, and are of a deep rich green colour.

**Carnations from Kelso.**—Messrs. Laing and Mather send us from Kelso a gathering of beautiful self Carnations which they grow so well. Among them Dundas Scarlet, a brilliant red, is very fine. Crombie's Pink, Duchess of Fife, William Wood, and the old Mary Morris are all worthy of note, the colours clear and very distinct.

**Setaria alopecuroides nigra.**—This striking and distinct annual Grass not often seen was represented by a large bunch in Sir Trevor Lawrence's group at the Drill Hall on Tuesday. It has strong stems, which grow about 2 feet high, clothed with large leaves, each about 8 inches long and 1 inch wide, and terminated by a thick drooping plume made up of myriads of flowers. It is a fine Grass for winter decoration when dried.

**Agapanthus Mooreanus** appears to me to be far too little known. Here it is undoubtedly quite a hardy plant: frost that kills down to the ground such things as Laurels, Laurustinus, &c., has no effect at all upon it, though wholly unprotected, and, more than that, it is very free flowering, the smallest bits producing one or more scapes. There are here literally hundreds in all

sizes and every one flowering. For the sake of a bit of blue in the garden it should be generally introduced; it is a first class hardy plant.—T. SMITH, *Neuryp*.

**Lilium Henryi** is just coming into flower at Kew, and although as yet comparatively new, there is every indication that it will be one of the garden Lilies of the future. It has been aptly called an orange-yellow *L. speciosum*, but it is besides endowed with great vigour and stature. Some of the strongest growths are between 7 feet and 8 feet in height and have from twenty to thirty flowers and buds upon them. It is a grand and stately Lily and distinct from all others. A coloured plate of it was given in THE GARDEN of November 7, 1891.

**Brunsvigia Josephinae** is one of a showy family of Cape bulbs that require to be grown in a greenhouse, but are rarely seen in this country. The bulb of the plant shown at the R.H.S. meeting on Tuesday was very large and bore two scapes, the larger one being of great size, terminated by an enormous head of flowers concentrated in an umbel. Each flower, however, is borne on a stem 9 inches in length, and the flowers radiate in all directions. They are of a deep blood-crimson colour. The leaves, which appear after the flowering season, are long, strap-shaped, and of a glaucous green.

**Chrysanthemum Walter Surman.**—An excellent coloured illustration of this Japanese incurved Chrysanthemum is given in the current number of the *Revue Horticole* of Paris. It is there called Walter Seaman, which is an error, for the variety was raised in America by a very successful seedling grower, Mr. Henry B. Surman, gardener to Mr. E. W. Clarke, of Philadelphia. Among other well-known novelties from this grower are Mrs. E. W. Clarke, Edwin Lonsdale, R. C. Kingston, Mrs. L. C. Madeira, Master Bates Spaulding, Welton Beauty, and Mrs. R. C. Kingston, the last named an incurved being certificated by the N.C.S. on December 4, 1894.—CHRYSANTH.

**Crown Daisies.**—It was a great pleasure to see the familiar old Crown Daisy of our gardens presented in such magnificent form as it was on Tuesday at the Drill Hall by Mr. H. Brownhill, of Sale, Cheshire. As will be seen by our report of the meeting, four varieties were selected for a distinct award, but apart from this the merit of the exhibit as a whole was great and the quality of the flowers much in advance of what has been hitherto seen. It is perhaps needless to multiply names in a race of annual flowers, but if we take them as a strain, it is one that should become popular in gardens provided the plants have good culture, such as Mr. Brownhill gives them in rows several feet apart. For late summer and autumn there could be no finer flowers than these to make the garden gay and fill the flower vases in the house as well.

**Lilium Lowi.**—Among the Lilies recently introduced from Barmah is this beautiful and distinct kind, which was well shown by Messrs. Wallace, of Colchester, at the Drill Hall on Tuesday. Some time back when visiting this nursery we saw a batch of *Lilium Lowi* that showed much variation in habit of growth, and as the bulbs were newly introduced it was thought possibly there were other species as well. They all proved, however, to be *L. Lowi*, and it is evidently subject to an amount of variation both in growth and in the amount of external colouring that suffuses the white ground colour of the flower. It belongs to the drooping tube-flowered group, and although as yet only about two blooms have appeared on a stem, there will possibly be more as the bulbs become established. The spots and markings in the tube of the flower are very rich and pretty. A coloured plate of this Lily was given in THE GARDEN of March 17, 1894.

**Geranium sylvaticum.**—Few things among hardy herbaceous plants are equal to *Geranium sylvaticum* for producing effect, and yet this plant appears to be rare, even although a strong grower, as it is seldom met with—in fact, I only

know two places where it is grown, viz., Baldersby Park, Thirsk, and Kirkham Abbey, York. At the latter place hardy plants are made a speciality of, and recently I saw among them two fine clumps of this *Geranium*, each 4 feet in height and as much in diameter, and a complete mass of flowers. The colour of the flowers, looked at in a mass, is a bluish purple, but on closer inspection it is seen that the petals are shaded with scarlet-purple towards their base. Besides being an excellent subject for the hardy herbaceous border, seeing that it not only produces an enormous quantity of blossom, but continues in beauty for six weeks or two months, it is also useful in a cut state for home decoration.—R. C. H.

**Snapdragons from Hawick.**—I was pleased to notice your correspondent's remarks about the white *Antirrhinum* in your last issue, as there is no plant better adapted for the flower garden, and when it is seen in masses with its two companions of exactly similar habit—the crimson and the yellow—it leaves nothing to be desired. I do not consider it a good plan to raise them from seed, as although you may get a percentage true, the result will be disappointing, and it is much better to raise them from cuttings in the autumn. I enclose a few spikes of each of the varieties.—J. FORBES.

\* \* \* The flowers sent are good and of simple colours, but it would be better not to seek novelty through dwarfing such plants, as the free and more natural growth is much better.—ED.

**Pæonia triternata.**—By this post I send you a couple of spikes of *Pæonia triternata* culled in the nurseries of Messrs. Veitch, Exeter. Though introduced a long time ago the plant is not often seen in English gardens. It grows about 18 inches high and has the double merit of being effective in spring as well as in autumn. The single rosy crimson flowers appear about May. But almost more effective than the flowers are the showy seed-pods, of which the enclosed is a sample. The pods are larger than those of most *Pæonies*, and though they open as soon as the seeds begin to ripen, the latter adhere for many weeks and are highly ornamental. Each pod contains from six to ten blue-black seeds the size of an ordinary pea and perhaps double that number of sterile ovules of a deep scarlet. The contrast of colour is very striking and lasts for a long time.—F. W. M.

**Flowers from Winchmore Hill.**—I am sending you a plant of *Linaria repens alba* to show how free-blooming it is. It has been in bloom since May. I am also sending you flowers of the white Dandelion. *Hedysarum multijugum* is still in full flower. *Haplocarpha Leichtlini* has stood the past winter well, and so has *Cineraria aurantiaca*, both remarkable plants for a winter like the past. *Geum Heldreichi* is also in full bloom, and is a favourite with everyone. *Geum Eweni* and *G. montanum maximum* are almost over. *Geranium sanguineum album* has also been flowering well. *Delphinium grandiflorum plenum* is beautifully in flower. How seldom this plant is seen, and yet at one time one of the commonest. One of the most effective masses I have is *Linaria dalmatica*; it is a sheet of bloom 18 inches high, the first shoots were 4 feet; this, like many other perennials, should be cut down when flowering is finished, and so ensure a succession. *Aquilegia glandulosa* and *Stuarti* have been flowering well, but many fail with them, which I think is owing to removing them at the wrong time; they should never be removed when dormant, but always when in full growth. *Helenium grandicephalum* is very good just now; a fine plant for a large border.—AMOS PERRY.

**Names of plants.**—*J. W.*—1, *Spiraea arifolia*; 2, *Spiraea Bumalda*; 3, *Ilex Shepherdii*.—*W. H. Smith.*—1, *Phytolacca decandra*.—*P. H. Breton.*—1, *Eucalyptus Gunnii*; 2, *Palurus* sp.—*Miss E. Breton.*—1, *Abelia rpestris*; 2, *Tellima parviflora*; 3, *Cassia floribunda*; 4, *C. lystegia pubescens* fl.-pl.

**Names of fruit.**—*W. H. Smith.*—2, Apple White Juneating.

No. 1240. SATURDAY, August 24, 1895. V. I. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## CHRYSANTHEMUMS.

### CHRYSANTHEMUMS IN RUSSIA.

THOUGH a beginner in Chrysanthemum growing, I nevertheless have had time to try all the different modes of training practised in England. I have grown (1) standards, naturally grown I should like to call them; (2) for getting big flowers I employed the English system, that is growing on the plants without stopping, finally taking up three or four of the best shoots after the first break; (3) cut-down plants; (4) bushes; and (5) plants with single blooms from summer cuttings.

First I should like to direct attention to the cut-down plants, in which I have always taken a great interest, being rather anxious to get good blooms upon dwarf plants. I must confess this method has not satisfied me, though I venture to say the plants have been well grown and clothed with dark foliage right down to the rim of the pots. The old Avalanche, for instance, grown upon this principle reached a height of no more than 24 inches to 28 inches; each plant had three or four shoots left with the same number of buds. So far I was very pleased, but when the flowering time came only one or two blooms opened, the others were blind. What is the reason of this? It was not one plant; there were about fifteen, all of which behaved alike. Avalanche grown without stopping developed beautiful blooms, three or four on each plant. This bad behaviour of Avalanche has happened with me two years in succession. There are other kinds which do the same—for instance, Bouquet des Dames, Puritan, and Edouard Audiguier. Of the last named kind I can get good flowers only from the single bloomed plants grown from summer cuttings. All the later kinds are cut down about June 1, and the earlier ones about June 15. I imagine that our cold climate has much to do with this strange behaviour. It is almost impossible to strike cuttings before February 1, and even if you have the chance of securing good cuttings before this time it is not worth while to strike them before the date named, because the cuttings inserted between February 1 and 15 will root more freely than those inserted during January and finally make better plants.

#### CUTTING DOWN.

Why do we cut down our plants? Of course the answer is, to get dwarfier plants, clothed with good foliage to the very pots and rather good flowers. Is there no other method with results like those of the cut-down system, but more simple, and perchance giving better results, for the north especially, than the cut-down one? All know that the time when the plants have been cut down is a rather critical one, and that one is obliged to bestow very much care upon the watering. If at the time when the plants have been cut down you have the misfortune to have a spell of heavy rain, you scarcely know what to do. Those who have plenty of room will put them into frames and be safe, and others will lay down the pots on their side; but if the rain goes on for a week or more you will get rather uncomfortable.

This season I have not cut down at all, because last year I have had such satisfactory results with another method—let me call it the

"half cutting-down." When the young plants have reached a height of about 7 inches or 8 inches I take off not the tips of the growths, but about 3 inches or 4 inches. To do this no knife is necessary, as the growth is yet sappy. Almost simultaneously the new growths appear, of which I select three or four of the strongest, and on these I take the first buds. As the young shoots come forth almost at once, there is no danger of over-watering. This is one advantage, but the other ones are not to be despised. First, such a plant does not grow taller than a properly cut-down one, and secondly, such plants flower earlier than the cut-down ones, and even earlier than the un-stopped ones. Grown on this principle, Stanstead White was from 28 inches to 30 inches high; naturally grown, I mean un-stopped, about 50 inches. The Puritan and Secrétaire Cassagneau reached nearly the same height. The flowers were good, not quite so large as those grown upon un-stopped plants, but the dwarf growth, the early flowering, and the relatively small pots used—7-inch—balanced this.

I often wonder that you are searching for very late varieties. For us they are utterly worthless. Chrysanthemums are naturally autumn flowers, and I think it is rather contradicting Nature to try to make them spring flowers. Last year I cut my last blooms about Christmas, and I was very glad they were over. About that time we have so many other flowers, the first fresh Roses, Lilacs, Lily of the Valley, Hyacinths, Tulips, Cyclamen, Azaleas, and so forth, which so remind us of the coming spring, that no one takes any interest in autumn flowers.

#### STANDARDS.

When I was in England I saw a good lot of Chrysanthemum shows in London and in its neighbourhood. When I first saw a Chrysanthemum show in your country I was quite astonished. But I did not see any standards, with the exception of a very few at the Crystal Palace, if I remember rightly, and even these did not please me. They were of a very stiff, but not artistic appearance, with the blooms distributed rather too evenly over the whole crown. I grow my standards without any wire rings, and only use one stick to every plant. The cuttings are secured as soon as possible and grown on with one stem till the first break appears; then I take up three to five shoots, and these are generally stopped about three times during the summer. There is no disbudding, and what beautiful heads of flowers you get in this way. The kinds I grow are Martinmas, Mme. de Sévin, Roi des Précoces, W. Holmes, Ulrich Brunner, Petite Jeanne, Alexandre Dufour, and Margot. This last named kind I grew for years in bush form, and I had almost decided to discard it on account of its straggling habit of growth. But I happened to give it a trial as a standard, and it is one of the most elegant Chrysanthemums I have got. I have also grown a few pompons, as Black Douglas, Mlle. Elise Jordan and such like. For half standards I recommend Fleur Parfaite and Norbert Puvrez, a truly charming kind. I have also tried the well-known *Seur Mélanie*, but there was something wrong; a large part of the buds was blind.

I am surprised that when one speaks of good early varieties for cutting, decoration and general purposes Martinmas has not been named. I consider this one of the very best early Chrysanthemums I have, as good among the pinks as W. Holmes among the browns. Last year I received William Seward. I hoped it might take the place of the tall *Jeanne Délaux*. The buds began to open and

the colour was beautiful, but when the flowers were fully open, unfortunately the beauty and the rich velvetyness of the colour were gone. The petals curled up and showed their reverse, of rather a faded hue. Does it always behave like this? The sun did not touch the blooms, I am sure. Does there exist any kind of the same lively, fine colour as Edouard Audiguier, but of a better and dwarfier habit of growth? Would it not be possible for some grower to give a list of the very best kinds of Chrysanthemums for every month, indicating their height and colour? I fancy that many beginners like myself would be grateful for such a list.

R. KATZER.

*Pawlowsk, near St. Petersburg.*

**The Chrysanthemum in France.**—M. H. Fatzer in a recent number of the *Revue Horticole* contributes an interesting article on the cultivation of large-flowering varieties of this popular favourite, dealing more particularly with those which he calls "la race Calvat." After a cursory review of the flower in America, in England, and in Australia, the writer proceeds to call attention to the need for some special Chrysanthemum committee being formed to work on lines analogous to those pursued by the N.C.S. of London. It is indeed strange that in a country like France, where so much has been done to improve and popularise this flower, no such body exists. M. Fatzer is an advocate for a committee being established by the National Horticultural Society of France, which committee should be composed of growers and experts, whose duties should be the examination of novelties and the awarding of certificates to meritorious exhibits, the organising of shows and appointing of judges, and furthermore the publishing of reports of the meetings of the committee containing lists of varieties and their adaptability for various purposes. We are told that the admirers and grower of the flower are on the increase, and that shows are more numerous all over France than ever. M. Fatzer's suggestions are therefore worthy of mature consideration by French nurserymen interested in the Chrysanthemum.—CHRYSANTH.

**Chrysanthemums on walls.**—The plants growing against walls have not made so much progress as in some seasons. The dry weather experienced during the months of May and June checked the growth considerably, especially where the plants lacked moisture at the roots. However, the foliage has an especially healthy tone about it, which augurs well for a good flowering season. Many of our plants at the foot of a south wall have been in their present position several years, and as they did not thrive during June as I cared to see them, I gave them a thick mulching of cow manure, covering it lightly with soil for the sake of appearance. Before putting on the soil I gave them a heavy watering, washing down to the roots much of the manurial properties contained. The plants are now progressing quite satisfactorily, and I expect good returns at the end of November when most of the ordinary indoor varieties are losing their freshness. Most of the branches are now making a natural break. If a few extra large blooms are wished for, this bud must be "taken," removing all growths that cluster about it. I, however, prefer a number of smaller blooms, and instead of pinching off the shoots I pinch off the bud and fasten the growths securely to the wall. I find nothing better for this purpose than the old-fashioned plan of using shreds and nails. If the shoots are left until they hang downwards, they become crooked and unsightly. Much better is it to fasten them up as growth proceeds: the wall is then much better covered, forming during the summer a dense mass of green.—E. M.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Eulalie Morel.**—This is one of the best early sorts. The colour is a shade of

mine-pink and the flower is of Japanese form. It also grows and flowers very freely.—H.

**Chrysanthemum Bronze Bride** should be added to the select list of early sorts for open air culture. It is a pompon, but rather large for the type, and assumes a fine bushy habit of growth. The bronzy rose-tinted blooms are distinct and pleasing.—H.

**Chrysanthemum Mme. Marie Masse.**—A fine bunch of the above early sort was exhibited among a collection of hardy flowers at a flower show the last week in July. It is a loosely-formed reflexed Japanese bloom of moderate size. The colour is pink of a nice shade. It is free and an excellent variety for open air culture.—H.

**Chrysanthemum M. Gustave Grunerwald.**—This early sort is now (Aug. 1) in bloom in the open border. It is a full reflexed-shaped flower about 4 inches across. The colour is a shade of nice bright lilac. It is very free flowering; so much so, that there is some difficulty in obtaining leafy bushes. As a pot plant under glass I do not think it so valuable as when allowed to blossom in the open air. The colour in the former position assumes a dirty, unattractive shade. The old stools require some protection in the winter, it being a somewhat tender sort.—S.

## ROSE GARDEN.

### CLIMBING ROSES IN FRANCE.

In the following article I wish to describe a very interesting collection of climbing Roses cultivated by MM. S. and P. Cochet, Rose growers, at Suisnes, near Grisy-Suisnes (Seine-et-Marne), and which I had the privilege of inspecting last June 23.

Without having seen it, it is absolutely impossible to imagine a more enchanting sight than is afforded by the perspective of lines of climbing Roses along the walks in a garden, where the multitudinous flowers, especially in the morning when the dew is on them, or in the evening when the sun is setting, readily recall to one's mind the embellished splendour of the gardens of ancient Rome, at least as the imagination loves to picture them. It is, indeed, a charming scene at this delightful time of the year, when Nature, in the full plenitude of her vigour, gratifies our sight with the flowers which she presents to us and which she produces for us in continuous succession. In the presence of such a spectacle, what stronger feeling can animate one's breast than the resolution of applying oneself with redoubled vigour to the culture of the Rose and to the improvement of the numerous varieties which have been already obtained?

At Suisnes the climbing Roses are grown in a simple manner without any elaborate device, their intrinsic merit and superb appearance being thereby greatly enhanced. Let the reader picture to himself a walk 13 feet wide and at least 162 yards in length running in a straight line from the centre of the dwelling-house, and exhibiting on both sides, at the height of about 8 feet from the ground, an unbroken line or garland of colour in which white, red, and pink more or less prevail, and he may form an approximate idea of the richness and elegance of this mode of embellishment. Each variety of Rose is represented by two specimens, which are planted opposite to each other, one on each side of the walk, so that the whole plantation is in this respect arranged with the regularity of a flower bed. The distance between the plants at the base of the stems is 8 feet. A rod of iron wire (No. 18) fixed perpendicularly and then bent horizontally at the top affords a ready

and regular support for the long branches of the Rose trees. I may add that on level ground (as it is at Suisnes) the shoots may be trained on both sides of the iron prop at the top, while on sloping ground they should, on the contrary, be trained to one side only, that is in the direction of the upward slope of the declivity. Amongst the numerous varieties of climbing Roses which I had time to examine at Suisnes a certain proportion seemed to me, from their vigour of growth, free flowering, and hardiness, to be worthy of special notice. These, which I am now about to enumerate, are respectively referable to four typical species, viz.: (1) *Rosa multiflora*, Thunberg (1781); (2) *Rosa setigera*, Mich. (1803), syn., *R. rubrifolia*, R. Br. (1811); (3) *Rosa alpina*, L. (1753); *Rosa sempervirens*, L. (1753); and also to the "*Rosa ayreshirea*" of gardens.

#### I.—ROSA MULTIFLORA.

The varieties which have sprung from this species are particularly characterised by the stipules or greenish appendages at the base of the leaves, being always more or less deeply pectinated, by which special feature the ever vigorous-growing shoots of *R. multiflora* de la Grifferaie (which is commonly used in budding) are easily distinguished from those of the finer varieties of Hybrid Perpetual Roses.

**ROSA MULTIFLORA (Thunb.)**—This typical species, which is too rarely met with in gardens, is of such vigorous growth that it easily attains a height of from 10 feet to 13 feet. The leaves are soft to the touch, and the flower-clusters, which are always very numerous, light and well furnished, are produced in long, erect, terminal, pyramidal panicles, which have a most graceful effect; the individual flowers are small, single, pure white, and rather resemble those of the Bramble. Unfortunately, as is also the case with most of the species or varieties which I am about to describe, this type is not perpetual-flowering; but it flowers so very abundantly in May and June, that I do not hesitate to recommend it here. A good many years since, MM. Cochet raised two varieties of *R. multiflora* with semi-double flowers and quite as vigorous growing as the type. One of these has pure white and the other pinkish-white flowers, and both possess considerable ornamental value.

**R. M. VAR. DE LA GRIFFERAIE.**—According to M. Crépin, Director of the Botanic Garden at Brussels, and a high authority on Roses, this well-known variety is a singular kind of hybrid between *R. multiflora* and *R. gallica*. The plant possesses the same vigour of growth as the preceding kind, but the leaves are larger, the flowers double and very large for the species, and change to a more or less vinous-pink colour as they advance in growth. In La Brie, this variety, which is to be recommended as a climbing Rose, is extensively used along with *R. canina* as stocks for budding the numerous varieties of Hybrid Perpetual Roses. It is very easily multiplied from cuttings of the woody branches put in in March, but when budding it is essential to success to operate upon a well-rooted stock which has stood for a year in a nursery bed instead of using cutting stocks which have just been planted out for the purpose of budding in the open ground, and which, not being regularly watered, cannot be depended upon to succeed so well. In this series I can recommend the following varieties:—

**R. M. VAR. GRAULHIER.**—An interesting form, with medium-sized double white flowers.

**R. M. VAR. A BOIS BRUN.**—In this the branches and foliage are of a very ornamental purplish hue, which produces a particularly good effect in a mixed plantation of climbing Roses.

**R. M. VAR. TRICOLOR.**—The flowers of this variety are nearly as large as those of *R. m. de la Grifferaie*, but are more globular in form, while the petals are crenulated and exhibit variable reflections of colour, being bi-coloured rather than truly tri-coloured, that is, they are pink and white.

In this group I may also include some specially fine kinds, some of which are described in the catalogues as varieties of *Rosa polyantha* (*R. multiflora* of Thunberg), and others as hybrids of the climbing Hungarian Rose.

**R. M. VAR. TURNER'S CRIMSON RAMBLER.**—A new variety, bearing rich clusters of flowers in ready-made bouquets. Individual flowers of medium size, semi-double, of a fine dazzling poppy-red colour, and with very downy flower-stalks.

**R. M. VAR. BENNETT'S SEEDLING.**—This variety comes very near the type in habit of growth and style of flowering, but the flowers are somewhat larger, semi double, and white, very slightly tinged with pink. It is also somewhat late-flowering, and is especially remarkable for its exceedingly numerous and well-furnished, erect-growing clusters of flowers.

**R. M. VAR. DANIEL LACOMBE.**—A very vigorous-growing variety, bearing small white flowers with a yellowish centre.

**R. M. VAR. PETIT POSTILLON.**—Flowers of medium size, very double, pink. (Climbing Hungarian hybrid.)

**R. M. VAR. MERCEDES.**—Flowers rather large-sized, well formed, and of a fine bright pink colour; prickles prominent. (C. H. hybrid.)

**R. M. VAR. GILTA.**—Flowers globular in form, double, lilac-pink. (C. H. hybrid.)

**R. M. VAR. MME. RICHTER.**—Flowers double, well formed, glazy-pink. (C. H. hybrid.)

**R. M. VAR. ERNST DOREL.**—Flowers rather large-sized, cup-shaped, deep pink. (C. H. hybrid.)

#### II.—ROSA SETIGERA.

The numerous varieties in this group are at once specially distinguished by their leaves being rough to the touch, shining on the upper surface, downy and glaucous underneath, deeply toothed at the margin, and furnished with curved prickles on the mid-rib and principal veins. The flowers are borne, mostly in threes, in numerous corymb-like clusters.

**ROSA SETIGERA (Michx.)**—A native of North America, this species, which is very rare in cultivation, is remarkable for its vigorous growth and hardiness. It is also very ornamental with its soft green, crimped leaves and its fine, bright pink flowers, which are of medium size and not quite semi-double. In this season I can specially recommend the following:—

**R. S. VAR. BEAUTÉ DES PRAIRIES.**—Flowers well formed, rather large-sized, globular in shape, and of a fine bright pink colour.

**R. S. VAR. MILL'S BEAUTY.**—A very vigorous-growing and most noteworthy variety, producing a brilliant effect when its flowers, which are of a redder colour, but not so double as those of the preceding variety, are in the full flush of their freshness. An extra fine kind.

**R. S. VAR. RUSSEL COTTAGE.**—A very vigorous-growing and floriferous variety, with medium-sized double flowers of a superb vinous-red colour.

**R. S. VAR. BELLE DE BALTIMORE.**—A vigorous-growing and very free-flowering variety, with medium-sized double flowers, white, slightly tinged with flesh colour.

**R. S. VAR. MRS. EDGEWORTH.**—Flowers medium-sized, very double, lilac-pink, with glandular flower-stalks, which impart to them somewhat of the appearance of Moss Roses.

**R. S. VAR. VIRAGO.**—The finest of the Roses which bear the name of Climbing Hungarian; flowers semi-double. An extra fine China Rose.

#### III.—ROSA ALPINA.

Not quite so vigorous-growing as the varieties of the preceding section, those which belong to this group have, as their chief characteristics, branches almost devoid of prickles, long, elliptical leaves with marginal teeth far apart, and stipules which are very broad, especially at the extremity. Amongst the handsomest varieties of this section are—

R. A. VAR. MME. SANCY DE PARABÈRE.—Flowers large, double, of a fine bright rose colour. An extra early-flowering variety.

R. A. VAR. CALYPSO.—A vigorous-growing and equally early-flowering variety, with large, double, flesh-coloured flowers.

R. A. VAR. ORNEMENT DES BOSQUETS.—Remarkable for its glaucous foliage and its fine pink single flowers.

R. A. VAR. GRACILIS.—A vigorous-growing variety with medium-sized double flowers of a fine brilliant bright pink colour.

R. A. VAR. ZÉPHYRINE DROUIN.—A variety with semi-double, almost single, brilliant red flowers, often described in catalogues as belonging to the section of Bourbon Roses, but considered by MM. Cochet as properly referable to *R. alpina*. It is possible, considering the vigorous habit of growth, the absence of prickles on the wood, and the highly-developed stipules of this Rose, that it might be a hybrid between *R. alpina* and *R. borbonica*. However that may be, I remember having seen in the year 1884 the Rose Zéphyrine Drouin very skilfully planted as a climbing Rose at Dijon, in the gardens of the Place Saint-Pierre, so as to form a kind of pyramidal furnishing to the naked stems of trees of *Acer Negundo foliis argenteis* which had been grafted as tall standards and formed round-headed specimens. This was done in the following manner: At the distance of 20 inches from the foot of each tree four iron wires were fastened to pegs in the ground, the free ends of the wires being then carried up and secured to the trunk of the tree just underneath the head of branches. A light invisible support was thus provided for the Roses, which were planted close to the pegs. The effect resulting from this arrangement was one of the happiest imaginable, and the plan is well deserving of recommendation.

R. A. VAR. BOURSULT.—This variety, which has single flowers of a fine red colour, is considered by M. Crépin (the authority cited above) to be a hybrid between *Rosa alpina* and *R. indica*.

#### IV.—ROSA SEMPERVIRENS.

Although rather delicate for the rough winter weather which now and then prevails in the neighbourhood of Paris, the varieties of this section are interesting from the peculiarity of their foliage being almost evergreen, the leaves being glabrous and shining on both sides, and also on account of their numerous flowers, which are mostly white, and are borne in corymbs of large dimensions. Among the finest varieties are:—

R. S. VAR. FÉLICITÉ-PERPÉTUE.—An exceedingly vigorous-growing and free-flowering variety, raised by M. Jacques at the Château de Neuilly in the year 1827. The flowers are of medium size, very double, white, slightly tinged with flesh colour when opening, but becoming paler as growth advances. Back or outside of the petals lilac-pink.

R. S. VAR. REINE DES BELGES.—An equally vigorous-growing and free-flowering variety, with medium-sized, pure white flowers. Extra fine.

R. S. VAR. FLORE.—A vigorous-growing variety, with spherical flower-buds and medium-sized, double, extra fine flowers, pink, changing to soft flesh colour, on long, graceful flower-stalks.

R. S. VAR. PRINCESSE MARIE.—A very vigorous-growing and free-flowering variety, with medium-sized double flowers of a handsome very light pink colour. This superb variety also was raised by M. Jacques at the Château de Neuilly.

R. S. VAR. THORESEYANA.—Flowers smallish, numerous, pure white; flower-buds cream-coloured.

R. S. VAR. AMADIS.—Flowers medium-sized, double, white; outside of the petals lilac-pink. A good variety.

R. S. VAR. MUTABILIS.—An extra fine variety, with flowers of a fine satiny pink colour.

R. S. VAR. A FLEURS ROSES.—Laffay.

#### V.—ROSA AYRSHIREA.

The varieties of this section are remarkable for their very vigorous habit of growth, their

numerous sharp-pointed prickles and their leaves being soft to the touch and composed of oval-acuminate leaflets regularly and finely toothed. The following selection is recommended:—

R. A. VAR. DUNDEE RAMBLER.—An exceedingly vigorous-growing and free-flowering variety, with small white flowers, which become slightly tinged with pink when fully expanded.

R. A. VAR. COUNTESS OF LEVEN.—A very vigorous-growing and free-flowering variety, with small, nearly double, very handsome pure white flowers.

R. A. VAR. SPLENDENS.—An exceedingly vigorous-growing variety, with medium-sized white flowers, slightly tinged with pink.

R. A. VAR. A FLEURS PLEINES.—A very vigorous-growing and free-flowering variety, with large-sized, almost double flowers of a pink colour, with golden-yellow reflections. An extra fine variety.

In addition to the foregoing choice varieties, the following kinds (belonging to other species) may also be mentioned, their value as ornamental subjects being beyond dispute:—

EVA CORINNE (Michigan).—A very vigorous-growing and free-flowering Rose, with large-sized, double, light red flowers.

ANNA MARIA (Michigan).—Flowers double, of a soft pink colour.

MALTON (Bengal hybrid).—A vigorous-growing variety, with medium-sized, double, scarlet-red flowers.

ROSA BRUNONI.—A singular and very vigorous-growing kind, distinguished by its glaucous foliage and its single, white, largish flowers, the yellow stamens of which produce a very fine effect.

Very recently MM. Cochet raised a double-flowered variety of *R. Brunoni* which is eminently worthy of note. It appears that such a double form is not entirely a novelty, but has already been introduced into cultivation, from which, however, it had almost completely disappeared.

ROSA POLYANTHA GRANDIFLORA DE BERNAIN.—According to M. Crépin, this is the true *R. moschata*, Herm. (1762), and synonymous with the preceding species, *R. Brunoni*, Lindl. (1820).

MÉTÉOR (Noisette hybrid).—This and Virago are beyond doubt the finest of the kinds known as Climbing Hungarian Roses. Flowers of a superb brilliant red colour.

Lastly, to conclude this copious enumeration of climbing Roses, I shall mention two varieties of this class raised by MM. Cochet, viz.:—

MARIE ROBERT (Noisette).—Flowers large-sized, globular in shape, with slightly ruffled petals, China rose colour with coppery reflections. Very fragrant. A superb variety.

MADAME PIERRE COCHET (Noisette), syn., Surpasse William Allen Richardson.—Flowers larger than those of the last-named variety, fragrant, of a fine nankeen-yellow colour, shaded with golden yellow. Foliage glistening. An extra fine variety.

These last two varieties belong to the group of climbing Roses of the Tea or Noisette section, with superb large flowers (not produced in great corymbs) in which yellow tints, orange, and copper colour are of frequent occurrence. These, however, in the climate of Paris, at least, are not so hardy as the Roses of the extensive and fine series which I have just enumerated. The only defect in this series is that it does not include any of the truly perpetual-flowering kinds. For all that, the cultivation of these climbing Roses cannot be too strongly advocated, especially in extensive grounds or parks where, as has been done at Suisnes, room could easily be afforded to form an avenue of them which at flowering time would present the most charming sight that the owner or occupier could wish for. These climbing Roses, of course, are equally useful for furnishing

fences, arbours, bare trunks of trees, &c. Most of the varieties are readily multiplied from cuttings, and also by budding on the wild Brier stock. The only attention which they require is to reserve, in the growing season, a certain number of vigorous young shoots at the base of each plaut and in spring-pruning to cut away part, if not all, of the branches which bore flowers in the preceding year. These will be advantageously replaced by the young shoots which have been retained as mentioned above, and which will eventually become branches laden with flowers.—CH. GROSDÉMANGE, in *Revue Horticole*.

**Rose General Jacqueminot.**—For usefulness it will be some time ere this old sort is beaten. In a walk through the Rose department of Jackman's, Woking, during the dry, hot weather of the end of June this variety appeared the most showy of all the crimson kinds and the least affected by the elements. When in good form it is a splendid flower for exhibition although the scarcity of petals renders it liable to open quickly, but for the garden as well as for forcing under glass it may be cultivated with a certainty of success.—H.

#### NOTES ON THE THREE N.R.S. SHOWS.

I do not call to mind any season when the whole of the three shows have been so satisfactory as those of this year. After so sharp a winter and an exceptionally dry spring and early summer many of us were agreeably surprised at the Roses from all parts as shown at Gloucester. York just previous broke the record in a class for seventy-two blooms, there being, if memory does not fail me, no less than eleven lots. But it was not necessary to have seventy-two distinct varieties, and we all know how very much this simplifies the staging of so large a class. At Gloucester there were eight in the premier class for nurserymen, seven put up in the twenty-four singles, while no less than ten competed for trebles of a like number of varieties. Both at the Crystal Palace and Derby the competition was above the average in numbers. At Gloucester there was a magnificent stand of forty-eight from Messrs. Harkness and Sons, and which contained a silver medal bloom in Comtesse de Ludre, probably the finest flower ever yet staged of this variety. There are many curious features to note when one attends these shows regularly. At Gloucester Messrs. Harkness and Sons won in the chief classes, and were closely followed by Mr. B. R. Cant. At the Crystal Palace the tables were somewhat turned, while at Derby Messrs. Harkness and Sons simply won in all the main classes for mixed Roses, besides again taking the silver medal for a H P., this time with A. K. Williams, in their winning stand for the Jubilee trophy. At Derby, too, Mr. B. R. Cant was second in no less than four of the chief classes for nurserymen (mixed Roses), and Messrs. Dickson, of Newtownards, Ireland, a close third. In more than one of these the competition was very close. Personally I think the Derby show the best of the three if we look at uniform quality. The best H. Perpetuals were at Derby, and the best Teas or Noisettes at Gloucester. The show at the Crystal Palace was good in every way, but not so fine as we might expect the show of the year to be. The prettiest lot of Hybrid Briers was at Gloucester, and I was much struck with a semi-double crimson named Jeannie Deans. Among several other new ones not yet in commerce this one was the best in my estimation. Garden Roses were fairly good both at Gloucester and the Crystal Palace, but I must confess to a surprise at Derby, for although so late for these charming Roses, they were better than at the two previous exhibitions. The most conspicuous Rose during the year has been Her Majesty. At the Crystal Palace it won the silver medals as being the best H. Perpetual in the show both among amateurs and nursery-

men. Mr. B. R. Cant's specimen was simply perfect. At Derby Mr. E. B. Lindsell won the medal for a H. Perpetual with Xavier Olibo, and, singular to say, this gentleman won with the same variety last season. Her Majesty won two silver medals, Comtesse de Nadaillac also two, Comtesse de Ludre, La Boule d'Or, Maréchal Niel, Xavier Olibo, A. K. Williams, Marie van Houtte, Ethel Brownlow, and Horace Vernet took the same honour once each. I believe that Comtesse de Ludre is the only one of the twelve that has not gained similar honours in previous seasons.

A. PIPER.

### SHORT NOTES.—ROSES.

**Rose Jean Cherpin.**—One does not often meet with this Rose now, and yet in colour it is among the most distinct of all. It is quite a violet-crimson. The flowers are not large, but well formed, and the tree is particularly robust and hardy.—H.

**Rose Laurette Messimy.**—This very distinct Rose is one of the more recent of the China sorts and is not too well known. Its rose shaded yellow blossoms are exceedingly pretty. Like the class, it is ree-flowering, and valuable for planting in a mass.—S.

**Rose Mrs. John Laing.**—As a good all-round Rose this has few equals. The size is large enough and shape perfect. It grows with particular freedom, is almost proof against mildew, highly fragrant, and a perpetual bloomer. At the Woking flower show on the last day of July a capital box of it was exhibited by Mr. Jackman.—S.

**Rose l'Idéal** is a charming variety for training against a wall. In many respects, such as size, shape of bloom, and growth, it resembles the popular W. A. Richardson, but the colour is different and most attractive. Yellow and red are the predominating shades, and over all is a dark metal-like tint not seen in any other kind. The sort is very handsome in the bud state; therefore valuable for button-holes.—S.

### NOTES OF THE WEEK.

**Tufted Pansies.**—Mr. D. B. Crane sends us from his garden at Highgate a lovely lot of Pansies of the rayless type. They are mostly seedlings, but one named Ethel Hancock is a gem, its flowers pure white, with a rich yellow eye. The scent of them all is delightful.

**Tufted Pansy J. F. Riding.**—I am sending you a bunch of tufted Pansy J. F. Riding. It is one of the freest in my collection (about forty of the best sorts), very sweet scented, and has remarkably long stalks, making it very useful for cutting.—AMOS PERRY, *Wickmore Hill.*

**Streptocarpus from Blandford.**—I am forwarding per to-night's post a small box containing Streptocarpus blooms, also photos of two plants in bloom. The cut blooms, I am sorry to say, are past their best. There were over 100 blooms fully developed at one time on each plant.—ARTHUR ALLSON, *Bryanston Gardens, Blandford.*

\* Very large flowers and very pretty in colour.—ED.

**Adiantum pedatum.**—This hardy North American Maiden-hair is a handsome outdoor Fern in places suited for its growth. In Mr. Sclater's charming Fern garden at Newick Park it grows luxuriantly, and there are here some of the best pieces that we have ever seen out-of-doors in any garden in the south of England, the tufts tall, with wide-spreading fronds, and a perfect picture of graceful, healthy growth.

**Nemesia strumosa.**—By same post we send you specimen trusses of this annual from our grounds at Exminster. What we wish to draw your attention to is the brilliant and various shades of colour we have by selection now obtained. In the beds we have all the shades, from creamy white through yellow and orange down to a deep

vivid crimson. The plants, through giving them plenty of room—nearly 2 feet apart—have thrown out sturdy branches bearing abundance of bloom, the individual flowers being larger and of greater substance than we hitherto have had them.—R. VEITCH & SON.

**Onoclea sensibilis.**—The conventional way of planting hardy Ferns in association with decaying roots and tree stumps has never yet given us a picturesque result. At Newick Park Ferns are planted in groups and spreading masses between the shrubs and flowers, and they make a very different picture. *Onoclea sensibilis*, instead of being confined to a solitary tuft, runs freely through the moist soil, and we saw rich masses of it covering many yards of ground with a luxuriant mass of its distinct fronds, growing as freely as the native Bracken and giving a beautiful aspect of graceful Fern growth all too rare in gardens.

**Francoa appendiculata.**—This hardy perennial deserves to be much more grown than it is at present. In a Sussex garden I noticed a very fine specimen measuring 2½ feet to 3 feet in height, which has stood several winters without any protection. The flowers are disposed similarly to those of the well-known Bridal Wreath, but the white flowers are shaded with pink, and have a deep crimson blotch towards the base of each petal. The leaves are deep green, 8 inches to 10 inches long, and deeply lobed, especially towards the base where the midrib is almost bare. It is apparently of easy cultivation.—F.

**Saxifraga peltata.**—This, when well grown, is a fit associate for Gunneras, Rheums, and other noble-leaved hardy plants, and all who have a deep moist soil should plant a group of it under conditions that favour the fullest luxuriance of leaf growth. A very fine group of it is one of the features of the Fern garden at Newick Park, where it sends up its strong, round, shield-like leaves on stems from 4 feet to 6 feet in height, some of the larger ones being nearly 2 feet in diameter. Several individuals of average height could easily have hidden in the group at the time we saw it. It is certainly unique among Saxifragas, which are nearly all of lowly growth.

**Roscoea sikkimensis** is a rare and beautiful perennial, now in full bloom in a border of the gardens at Offington, where it has proved hardy for several years. The plant at a first glance somewhat reminds one of *Tradescantia*. It grows about 18 inches high, and has slightly undulating sessile leaves, about 8 inches long and three-quarters of an inch wide, with entire margin. The stems are stout in proportion, being nearly half an inch thick, and bearing at the top several peculiarly-shaped deep purple flowers with yellow anthers. The under lip is very large, deflexed, and measures about an inch across, while the upper lobe forms a small pointed hood with a white centre.—F. W. M.

**Polygonum filiforme variegatum.**—This handsome Japanese Knotweed is perhaps the most distinct and beautiful variety of its class. It is still very rare, unfortunately, but has proved to be perfectly hardy in Sussex, where I noticed a compact bush about 2 feet high and 2½ feet in diameter in a half-shady position at Offington, Worthing. The large oval or oblong leaves, each about 5 inches long and 3 inches wide, are beautifully variegated with white. It is a most effective plant, and its leaves look more like those of the well-known stove plant *Ficus Parcellii* than those of a plant that can be grown out of doors.—F. W. M.

**Angræcum Scottianum.**—The *Angræcum* combine to as great a degree as any other tropical genus of Orchids that beauty of flower and remarkable structure which together form the chief attraction of the natural order. *A. Scottianum* is one of the most interesting and attractive of the smaller species. Its foliage is terete, the leaves being in two opposite rows, about 4 inches long and of the thickness of a small pencil. The flowers are very rarely seen more than one

on the scape. Like nearly all the *Angræcum*s, they are white, the lip, which is the largest and most conspicuous part of the flower, being of a purer shade than the sepals and petals, which have an ivory tint. The lip is about 1½ inches across and of somewhat rectangular shape, lengthening out behind into a slender spur 5 inches long. The species is a native of the Comoro Islands, which are situated between the northern point of Madagascar and the East Coast of Africa. It was discovered by Sir John Kirk about seventeen years ago.

**Tiger Flowers (Tigridias).**—The acquisition of several new and very beautiful varieties of *Tigridia* has caused more attention to be turned to them, and they deserve it. If they cannot be planted in the garden and left to take care of themselves, very little extra trouble is involved in lifting them in autumn and replanting in spring. At Kew recently we saw a bed of the orange-yellow Tiger Flower covered with gorgeous flowers, the effect such as no words can describe. At the Drill Hall on Tuesday, Tigridias were admirably represented in the group from Messrs. Wallace and Co., of Colchester. In addition to the older and better known forms, they showed some grand flowers of *T. lilacea*, which was figured in THE GARDEN of March 31, 1894, and another gem—*T. grandiflora immaculata*—of a unique character among Tiger Flowers, having none of the striking blotches of colour seen in other forms, but a self flower of noble form and purity, white, with a pale sulphur suffusion on the edges of the inner segments.

**The Tree Mallow (Hibiscus syriacus).**—This is one of the most beautiful flowering shrubs to have and enjoy in the garden during the late summer and early autumn months, and yet, strange as it may seem, we hardly ever see it. It comes into bloom when shrubs chiefly are flowerless, and gives a succession of beautiful blooms for several weeks, whilst its importance is now the greater by reason of the rich variety of pretty colours that are now to be had. We saw some charming bushes at Newick Park the other day profuse in bloom from top to bottom, one with flowers of the purest whiteness especially conspicuous, and a gem among flowering shrubs at any time. In Battersea Park at the present time it is also flowering well. Although this shrub is not a success perhaps in poor light soils that dry up quickly, there are plenty of places where it would thrive and be a source of interest late in summer. Although some might have avoided the Tree Mallow in the past because of the dingy purple tone of colour that certain varieties possess, this should not deter them from planting it now that varieties are to be had in brighter and lovelier hues. Those in pure white, soft pink and rich rose must surely please even the most sceptical in flower colours.

**Campanula Vidalii.**—I was much surprised to find this lovely greenhouse plant flourishing out of doors in Major Gaisford's garden. Whether it will really stand the winter remains to be proved, but even if planted out only for the summer months the plant would be a decided acquisition. It has very thick woody stems and forms a compact shrub with spatulate, large, fleshy and serrated leaves, 3 inches to 4 inches long, looking more like a large form of *Mesembryanthemum* or *Sedum* than a *Campanula*. The specimen here referred to is little more than a foot in height, but throws up its long racemes of flowers in an oblique direction on a stiff stem 18 inches long and bearing eight to ten large campanulate white flowers, which are very viscid and waxy in appearance. The wide corolla has at the bottom a fleshy disc-like receptacle, white in colour and nearly three-quarters of an inch in diameter, surrounded by a broad band of the deepest orange. From the centre of this receptacle springs a large white club-shaped style of fleshy appearance, and fitted at the top with a three-lobed stigma of peculiar form. Both leaves and stems exude on breaking a milk-white sticky sap similar to that of *Euphorbia*.—F. W. MEYER, *Exeter.*

## STANTON HARCOURT.

THIS is the ancient home of the Harcourts, and doubtless centuries ago was the stronghold of the surrounding country, whilst the land for miles around, it is known, was vested in the Harcourts of that period. The Stanton Harcourt of to-day is but a relic of a distant past, and appeals more to the antiquarian and historian than to the lover of gardens and flowers. There is plenty to show that the ancient house was once of great extent, but much has been carried away to another part of the county, and used in the erection of another house. It is a great pity that such a building, whose existence in part has quite outlasted the passage of centuries, could not have been preserved in its entirety, and surrounded by a

volume of "Homer," having sought out this secluded place where he could work undisturbed. The place is rich in its associations of literature, history, and architecture, but there is nothing to show that gardening has ever flourished here.

## TREES AND SHRUBS.

## THE SHRUBBY POTENTILLAS.

WHAT few yellow-flowered shrubs we have in the late summer season belong chiefly to the Genista family and to the Hypericums.

POTENTILLA FRUTICOSA, however, a member of the Rosaceæ, is at present the most attractive

previous one, but smaller and glabrous. The flowers differ also in being white. It is of interest botanically more than horticulturally. It was introduced many years ago from Siberia by the Loddiges firm, of Hackney.

P. SALESOVIANA is a third species, quite distinct from the two preceding ones. It is of looser habit, and differs markedly in the larger and distinctly pinnate foliage, which is bright green above, but covered beneath with a beautiful silvery down. The flowers are in loose cymes, and each measures about  $1\frac{1}{2}$  inches across the spatulate petals. The colour is a faintly rose-tinted white. P. Salesoviana is a native of the Altai Mountains, and is also common on the Cashmere Hills.

These three species, which constitute the shrubby section of Potentilla as represented in

Stanton Harcourt, Oxford. Engraved for THE GARDEN from a photograph by the late Mr. J. L. Robinson, C.E., Dublin.

beautiful garden, for which the situation is most inviting.

Stanton Harcourt is not many miles from Oxford, and stands in the midst of an undulating and fertile district. The portion shown in the engraving is the ancient kitchen, and the date when this was erected antiquarians have been unable to settle, although repairs that date back to the earliest part of the fifteenth century are apparent. This kitchen has no chimney, but the fires were made on the hearth and the smoke found its way out of the lantern erection at the top, which is provided with a series of shutters that were closed or opened according to the direction of the wind. An ancient tower of more recent erection than the kitchen is also well preserved. Its lowest story served as the domestic chapel of the place. Ascending by a winding staircase of stone the third and top-most story is reached, and here Pope in the year 1718 finished his translation of the fifth

shrub in bloom with yellow flowers. It is one of the most widely distributed shrubs in the Northern Hemisphere, being found in Europe (Great Britain), Asia, and North America. As might be expected from this, it exhibits considerable variation, but the differences are chiefly in habit and leaf, the flowers being always yellow. It is a bush of neat rounded habit, varying from 1 foot to 3 feet in height. The leaves present a sort of combination of the digitate and pinnate arrangement, and the leaflets (varying in number from three to nine) are sessile, oblong-lanceolate, and more or less hairy. The dwarfest forms of this species are the most tomentose and have the fewest divisions to the leaf. The flowers are borne in corymbose clusters, each one being from 1 inch to  $1\frac{1}{2}$  inches in diameter, and of a bright Buttercup shade of yellow. The exceptional brightness of the earlier part of this summer has apparently suited this Potentilla, for it is now, and has for some weeks been crowded with blossom.

P. GLABRA (or davurica) is a dwarf species possessing foliage of the same character as the

English gardens, are of easy cultivation. They like a fairly rich loam to grow in and love abundant moisture, P. fruticosa being not infrequently found in swampy situations in a wild state. W. J. B.

## HYDRANGEAS IN SUSSEX.

DURING a recent visit to Major Gaisford's very interesting garden at Offington, Worthing, I was much impressed with the beauty of various Hydrangeas then (beginning of August) in full bloom, and a short description of the principal varieties as I saw them may interest readers of THE GARDEN generally.

HYDRANGÆA HORTENSIS VARIEGATA is represented by a compact bush about 4 feet in diameter, with handsome, rather glaucous, distinctly variegated leaves and numerous white flowers, changing to pink, borne in large paniced, flat corymbs.

HYDRANGÆA H. TRICOLOR.—This is most ornamental, and forms a bush in size similar to the

last, but the leaves are larger, 5 inches to 6 inches long, deeply crenate, green in colour, but striped and mottled with white, and surrounded at the margin with a broad irregular band of bright golden yellow. The flowers, too, are distinct and ornamental, the small fertile blossoms being of a deep purplish rose colour, while the large sterile flowers are white, changing to pink.

**HYDRANGEA H. JAPONICA VAR. ROSEO-ALBA.**—This at Offington forms a noble bush quite 5 feet through. The serrated leaves are small, ovate, measuring scarcely more than 2½ inches by 2 inches, but the exquisite flowers, which were fully expanded when I saw them, render this shrub most effective. The fertile flowers are white, and surrounded by very large sterile blooms, white in colour, but profusely blotched and suffused with the brightest crimson, the two colours forming a most effective contrast.

**HYDRANGEA MANDSCHURICA.**—This is represented by a handsome bush measuring 6 feet through. The foliage is similar to that of *H. hortensis*, but the stems are of a glossy black colour, and the flowers form large, almost globular heads, composed of large blooms of a delicate pink colour, suffused with white.

The varieties Thomas Hogg, *H. paniculata grandiflora*, and others are also represented, but are too well known to need description. Of the many other rare and beautiful plants contained in this garden I hope to speak again, but the *Hydrangeas* mentioned were so perfect, that they well deserve a separate notice in this their flowering season. F. W. MEYER.

*Exeter.*

**Spiræa Bumalda Anthony Waterer.**—The flowers of this *Spiræa* are decidedly less bright than they were this time last year, though just as freely produced. If this *Spiræa* originated from a sport, it is greatly to be hoped that such a desirable shrub as this is not showing a tendency to revert to the type from whence it sprang.—T.

**Platycrater Sieboldi.**—This handsome *Hydrangea*-like shrub is quite hardy in Major Gaisford's garden, near Worthing, where a well-grown specimen, about 4 feet in diameter, is now in full bloom and most attractive. The leaves are opposite, lanceolate, with dentate margin, and 4 inches to 5 inches long, by 1 inch in width. The flowers appear in corymbs, and consist of four green sepals and the same number of thick, white, fleshy petals, somewhat deflexed, and forming a handsome corolla about 1 inch in diameter. Some of the flowers have petaloid stamens, but in most cases the latter form a conspicuous cluster, consisting of a very large number of creamy yellow anthers on very slender filaments.—F. M. Meyer, *Exeter.*

**Solanum arboreum.**—Among hardy plants for sheltered localities in the south of England few can surpass this lovely *Solanum*. Last winter it did not survive the extreme cold, but the winter before it did not suffer. At Offington a specimen planted against a wall is now in full bloom. The plant is about 4 feet high, with deeply lobed leaves about 8 inches in length. At intervals of an inch or more the midrib of the leaf is covered with very sharp brown prickles. The young shoots produce half way between every two alternate leaves a large raceme of six to nine flowers; these are white, suffused with very pale blue or lilac on the under side of the petals, and a cluster of deep orange anthers in the centre. As each individual flower measures about 1½ inches in diameter the plant has a very noble appearance.—M.

**Sutherlandia frutescens.** Among shrubs flowering in August, few can surpass this brilliant Cape Bladder Senna, which is hardy in sheltered places near the south coast, and does well in Major Gaisford's garden in Sussex, where a plant about 2½ feet high is now in bloom. The branches, stems, and under side of the pinnate leaves are covered with minute hairs, and the flowers appear in axillary racemes composed of from six to eight bright scarlet blossoms of the usual pea shape, the erect standard being suffused with white in the centre. The inflated seed-pods are

similar to those of *Colutea arborescens*.—F. W. MEYER, *Exeter.*

**Actinidia Kolomikta.**—Perhaps the finest plant in the country of this beautiful leaved plant is growing against a south wall at Offington, Sussex, where it has stood unprotected for fifteen years and covers a space of 8 feet by 4 feet. The leaves are cordate in shape, 2½ inches to 3 inches in diameter, with serrate-dentate margin and reminding one of the Lime tree. But the bright green leaves are continually changing colour, first becoming white at the apex and often halfway down the leaf, then turning gradually to all shades of pink and brown. The flowers are white.—F. W. M.

**Cytisus nigricans.**—As the summer wears away the number of leguminiferous shrubs in bloom becomes smaller and smaller, late spring and early summer being the high tide of the flowering season of these shrubs. There are still a few in bloom, however, and of them none better deserves notice than *Cytisus nigricans*. This has trifoliate, deep green leaves, and the flowers are borne on a long slender raceme, which stands erect, upwards of a foot in length, at the end of each shoot. The lower flowers open first and are long past before the topmost ones are expanded, thus the plant remains for a good many weeks in bloom. They are bright yellow, the misleading specific name referring to the fact that the whole plant turns black when dried for herbaria. There is a variety of this Broom called *longispicatus*, which is said to produce larger spikes, but I have raised seedlings from both which do not show any difference when given similar treatment. The species is a native of South-eastern Europe, and was introduced to Britain in 1730. It ripens seed freely, and this affords the best and quickest means of increase.—B.

**Ceanothus Gloire de Versailles.**—There are numerous varieties and species of *Ceanothus* now in cultivation, but the majority require the protection of a wall to enable them to survive our winters without severe injury or even death. *C. azureus* and its now abundant varieties appear to be the hardiest, and of these the one named *Gloire de Versailles* is perhaps the best. A large bed of it in the arboretum at Kew passed through the frosts of last January and February without more injury than the cutting back of the young herbaceous points of the branches; they were simply protected by spreading a layer of dry leaves 6 inches or 8 inches thick over the ground. With the advent of milder weather the plants broke freely into growth, and the bed is now a beautiful mass of rich blue flowers. *C. azureus*, which has paler flowers and smaller panicles, is a native of Mexico, but the genus is represented most abundantly in California. The easy production of varieties, as evidenced by the number sent out by Continental nurserymen, is due to the readiness with which they hybridise. Even in a state of nature it has been noticed by botanists that species growing near together are nearly always found to have their characters united in forms which no doubt owe their origin to cross-fertilisation by insects.

#### HYDRANGEAS AT KEW.

IN addition to their showy blossoms, the *Hydrangeas* are especially valuable from the fact that they do not bloom till the majority of hardy shrubs are over. The common *Hydrangea* is known to everyone, but not so the variety *Lindleyana*, of which a coloured plate was issued with THE GARDEN, December 1, last year. Of this there is a large bed at Kew filled with neat compact bushes about 2 feet high and plentifully furnished with blossoms, arranged, as in most of the species, in large flattened cymes. Unlike the common *Hydrangea*, whose head of blossoms consists almost entirely of large sterile flowers (for the small fertile ones are completely hidden by them), those of the variety *Lindleyana* are arranged in quite a different manner. In this the centre of the cyme consists of the small fertile blossoms,

which are of a pleasing shade of blue, and the showiest part of the inflorescence, that is, the large sterile blooms, are arranged in a somewhat irregular manner around the outer portion of the head of blossoms. These sterile flowers are when first expanded nearly white, but they soon become more or less flushed with red, and some of them are particularly bright. In many of the blooms the rich colouring takes the form of an irregular band around the margin of each petal. As the last severe winter did not injure this *Hydrangea* to any extent, it must certainly have a place assigned it among the very best of the late summer and early autumn-flowering shrubs. Besides the varietal name of *Lindleyana* it is also at times met with under that of *roseo-alba*. Two or three plants of another beautiful and distinct form occur in the same bed at Kew. This is *H. stellata rosea*, which, though about the same height as the last, does not branch so freely, and consequently as a bush is less dense than the variety *Lindleyana*. The flowers are arranged in much the same manner, but the fertile ones are white, and the large sterile blooms greatly surpass those of *H. Lindleyana* in richness of colouring. When first expanded the blossoms are nearly white, then they become flushed with red, till finally they are entirely of a glowing crimson-lake slightly marbled in many instances with white. Owing to the different habit of this, there is not, of course, such a mass of bloom as *Lindleyana* produces; still, the colouring is so rich as to at once attract attention.

There are several other *Hydrangeas* in bloom, but some of them are not particularly showy. An exception must, however, be made in the case of the popular *H. paniculata grandiflora*, which is at Kew associated with the typical *H. paniculata*, so that their relative merits can be readily compared. *H. paniculata* itself is more robust than the other and equally free-blooming, but the number of large sterile blooms in a cluster is very much less than in the case of the variety *grandiflora*; hence a flowering bush is not nearly so showy as this last mentioned. The blossoms of *H. paniculata grandiflora* will in a sunny spot become flushed with red as they get old. The common *Hydrangea* is also in many cases wonderfully showy, and so is the variety *mandschurica* or *cyanoclada*, characterised by the blackish tint of the bark and leaf-stalks, especially on the young shoots. This last is often brought in quantity into Covent Garden Market during the season. One prominent feature in connection with the different *Hydrangeas* is that they can all be very readily struck from cuttings, put in a frame at any time during the growing season, and they grow away rapidly afterwards. They will strike well enough now, but if put in about midsummer will root in a few weeks, when they may be potted off and will soon become established in small pots, in which they may be wintered in a cold frame. H. P.

#### FLOWER GARDEN.

##### THE PERENNIAL GENTIANAS.

If the genus *Androsace* may be considered to be the most alpine of all, the *Gentians* form of themselves a group of essentially mountain plants. It is true that some kinds of them are found on elevated ridges near the snow line, and that some kinds grow in marshy places on the low grounds, but the vast majority of these plants have their native habitat in the mountain regions of both hemispheres. Their flowers, which are of large size, sometimes very large for the dimensions of the plant, the richly coloured tints of their corollas, their graceful aspect and the architectural build of some species formed, ages ago, the subjects of enthusiastic descriptions and opened to many species of *Gentian* the garden gates of our forefathers. According to Paxton, *Gentiana lutea* was introduced into English gardens in the year 1596, while the date

of the introduction of *G. acaulis* is so remote, that all record of it has been lost. But it is not much earlier than the commencement of the present century, and especially after the year 1850, that the Gentians, no longer confined to botanic gardens, have been utilised for the embellishment of private gardens, flower beds, and rockwork, and it is entirely a result of the special culture of alpine plants that these brilliant

adapted for growing on rockwork, but are equally suitable for culture in the open ground, provided that a special compost is used to plant them in.

**GROUP III. GENTIANA VERNA.**—Containing dwarf species with sessile flowers growing little above the level of the ground, and forming more or less dense and compact tufts of foliage. These should be grown on rockwork, or, with special treatment, may be cultivated in the open ground.

**GROUP IV. GENTIANA PURPUREA.**—To this group belong those alpine species which are difficult of culture, and cannot be grown without some special knowledge and practical experience.

**GROUP I.**

**GENTIANA LUTEA (L.).**—A tall-growing plant with an erect stem 3 feet to 4½ feet high, and sometimes taller than this. Leaves broad, large, oval, opposite, forming quite a bush near the ground, and sometimes from 14 inches to 16 inches long and from 6 inches to 8 inches broad, very much veined, and of a glaucous green colour; stem leaves arranged in tiers 10 inches to 12 inches apart, and diminishing in size as they approach the top of the stem. Flowers yellow, produced in clusters from the axils of the leaves, and forming a long erect spike with

vacant intervals. Blooms from July to September. Its habit of growth is noble and majestic, its aspect is quite architectural, and everything relating to this fine species contributes to impart to it an air of greatness which induces the spectator to pronounce it, in the words of an English enthusiast, "a glorious plant." It is highly effective on rockwork and on the slopes of undulating ground in landscape gardens, and may be also advantageously planted as single specimens here and there in parks and pleasure grounds. On rockwork it requires a compost of good vegetable mould, leaf soil, and sand, and should be fully exposed to the sun. If planted in the open ground it should be in a deep, mellow, calcareous soil rich in humus. From the roots of this plant is made the liqueur or cordial commonly termed "Gentiane." The plant is propagated only by sowing the seed, and when once established it does not like to be disturbed from its position. In the alpine garden here we sow the seed in November in a cold frame, and the seedlings make their appearance in the following March and April. In May and June we prick them out under a cold frame, and in August we transfer the young plants to pots, in which they are kept as long as possible before they are sold or sent away. We have observed that if the roots of the young plants sustain any injury in the process of transplanting or potting, the growth of the plants will be checked or even seriously affected thereby. *Gentiana lutea* is found in the wild state on the calcareous mountains of Central and Southern Europe at an altitude of 500 metres to 1000 metres. Some hybrids of this and allied species are in cultivation.

**G. ALBA, Muhl. (G. ochroleuca, Lims.).**—An erect-growing, rigid, very glabrous plant, 12 inches to 16 inches high. Leaves lanceolate-oval, broad at the lower part of the stem and very narrow at the upper part. Flowers white, more or less dotted with yellow or green, and borne in a terminal head. Native of the mountain regions of the United States of America. Culture as for *G. Pneumonanthe* or *G. asclepiadea*. Rarely met with in cultivation.

**G. ANDREWSI (Griseb.).**—A plant with an erect stem 8 inches to 10 inches high, furnished with opposite, lanceolate-oval, acuminate leaves. Flowers almost sessile and borne in terminal cymes; corolla of a violet-blue colour, from 1½

inches to nearly 2 inches long, the divisions meeting at the apex in such a manner as to give the flower the appearance of an unexpanded flower-bud. Blooms in July and August. Found in moist places on mountains in the United States of America. There is a variety of it in cultivation which has white flowers. Culture as for *G. Pneumonanthe*.

**G. ANGUSTIFOLIA (Miehaux).**—Stems slight and flexible, from 12 inches to 16 inches high, furnished with linear, rigid leaves of a dark glistening green colour, and bearing from one to three funnel-shaped flowers of a sky-blue colour and 2 inches or less in length. A variety of it is in cultivation which has pure white or greenish flowers. Blooms in July and August. Native of moist forests in the United States of America. Culture as for *G. Pneumonanthe*. This species is rarely found in cultivation on the Continent, where *G. Saponaria* or *G. cruciata* is very often sold under the name of *G. angustifolia*.

**G. BIGELOWI (A. Gray).**—This species is very closely allied to *G. affinis*. Leaves narrow, linear, opposite, furnishing a stem 12 inches to 16 inches high, the upper half of which is, in the blooming season, transformed into a long spike of flowers alternating with the leaves from the axils of which they are produced; corolla of a violet colour, and in shape like a cylindrical tube terminating in a funnel with five lobes, which are oblong, acute, and ciliated at the edges. The flower-spike is rather like that of *Campanula spicata*. Blooms in July and August. Native of the Rocky Mountains from Colorado to New Mexico, at an altitude of 2000 metres to 3000 metres. Culture as for *G. lutea*.

**G. BURSERI, Lapeyr. (G. hybrida, Vill.).**—A plant with a stout stem 6 inches to 8 inches high.

Vernal Gentian (*Gentiana verna*).

daughters of the mountains are now to be seen growing around our dwellings. For a long time lovers of alpine plants, who were at first few in number and uncertain and empirical in their treatment of these plants, grew them on small rockeries apologetically hidden in some remote corner of the garden. But ever since Messrs. Edouard André and Wm. Robinson gave the sanction of their high authority to the culture of these plants, which they advocated both in their writings and by practical example, the cultivators of alpine plants have taken courage, and now claim for their favourites the first and best position in gardens or parks of the highest pretensions.

The Gentians belong to the natural family of the Gentianaceae, which is a well-marked one, comprising forty-nine genera, of which the genus *Gentiana* is by far the most important, as it contains nearly 100 species. These are scattered over the mountain regions of both hemispheres, the great majority of them being natives of the northern hemisphere, where they are found on the Alps, the Himalayas, in Siberia, on the mountains of N. America, and in the Arctic regions. Several species occur on the Andes of S. America, in Tasmania, Australia, and New Zealand. I do not know whether any species grow in Africa, except perhaps on the mountains of the Mediterranean region. They are, for the most part, perennial plants with fleshy roots which contain very bitter juices. Of annual Gentians there are less than thirty species, and the culture of these presents no great attraction to the great majority of amateurs. From an entirely cultural point of view, the perennial Gentians may be divided into four sections or groups as follows:—

**GROUP I. GENTIANA LUTEA.**—Comprising the species whose roots are more or less stout, and which are of a tall-growing habit, and are suitable for furnishing borders as well as rockwork, or may be used as subjects for landscape gardening.

**GROUP II. GENTIANA ACAULIS.**—Including low-growing species whose roots are not so stout as those of Group I., and which are better

*Gentiana affinis*.

Radical leaves large, lanceolate-oval, very much veined (five or six veins). Flowers large, pale yellow, dotted with purple on the inside, sessile, and borne in clusters at the extremity of the stem and in the axils of the uppermost leaves. Blooms in June and July. Native of the alpine region of the Pyrenees. Culture as for *G. lutea*.

**G. CRUCIATA (L.).**—Forms tufts of foliage of a cheerful green colour. Leaves broadly lanceolate-

oval, veined. Stem at first creeping, then rising erect to a height of 10 inches to 12 inches, and furnished with opposite lanceolate leaves. Flowers small, numerous, borne in terminal clusters; corolla sky-blue, with four oval acute divisions, which are of a paler colour on the outside. Blooms from June to August. Native of warm calcareous hills in the mountain regions of Central and Southern Europe, Asia Minor, and Siberia. Culture as for *G. lutea*; it likes limestone and full exposure to the sun.

*G. DEUMPENS*, L. (*G. adscendens*, Pall.).—Stem erect, 12 inches to 16 inches high. Leaves lanceolate-linear, thick. Flowers numerous, of a fine blue colour, and borne in terminal spikes. Blooms from June to August. Native of Siberia at an altitude of 500 metres to 1500 metres. Culture as for *G. lutea*.

*G. FETISOWI* (Rgl. and Winkler).—Stem solitary, erect, 6 inches to 10 inches high, furnished with narrowly-lanceolate leaves. Flowers sessile, borne in a terminal cluster. Corolla tubular, with five spreading lobes, and of a dark violet-blue colour; tube of a light lilac colour on the outside. Blooms in May and June. Native of the mountains of Turkestan at an altitude of 1000 metres to 2000 metres. *G. Olga* (Rgl. and Schmalh.), a native of Siberia, comes very near this species. Culture as for *G. lutea*.

*G. GELIDA* (M. B.).—Stems prostrate at first, then ascending, 8 inches to 10 inches high, furnished with narrowly-lanceolate leaves, and bearing at their extremity a spike of pale yellow flowers with five oval lobes, which are not ciliated. Blooms in June and July. Native of the alpine regions of the Caucasus and Armenia. It requires a light, deep, cool soil, and full exposure to the sun, and does well on rockwork. This species is seldom met with in cultivation true to name, as *G. septemfida*, which has a general resemblance to it in habit and foliage, is very often substituted for it by plant-dealers.

*G. KESSELINGI* (Rgl.).—Stems 8 inches high, bearing linear-lanceolate leaves, which have from three to five veins. Flowers white, borne in a closely-set terminal spike. Corolla tubular, swollen at the middle, and dotted with green on the inside. Blooms from May to July. Native of the alpine regions of Eastern Turkestan. Culture as for *G. lutea*.

*G. MACROPHYLLA* (Pall.).—Stem erect, 16 inches to 20 inches high. Radical leaves from 10 inches to 12 inches long; stem leaves smaller. Flowers blue, small, numerous, borne in closely-set terminal heads. This species comes very near *G. cruciata*, from which it is chiefly distinguished by the size and shape of its leaves, the divisions of the calyx, which are different in form and sometimes five in number (in *G. cruciata* always four), and lastly, by the lobes of the corolla standing erect instead of spreading out. Blooms in July and August. Culture as for *G. lutea*.

*G. OLIVIERI* (Griseb.).—Stem erect, 8 inches to 10 inches high. Radical leaves oblong, five-veined, stem leaves narrow. Flowers shortly stalked and borne in a loosely-set corymb; corolla dark blue, 2 inches or less in length. Blooms from June to August. Found in pastures in the mountain and sub-alpine regions of Asia Minor, Turkestan, and Songaria. Culture as for *G. lutea*.

*G. ASCLEPIADEA*, L. (*Pneumonanthe asclepiadea*, Schm.).—A species with long, slender stems from 20 inches to over 3 feet high, arching gracefully with the weight of flowers and foliage, and furnished with opposite, lanceolate-oval, much-veined, non-glistening leaves. Flowers blue, numerous, borne in a handsome terminal spike, in which the large dark blue corollas alternate with the leaves. Blooms from July to September. This species requires a shady or half-shady position and a moist, deep soil rich in humus, and may be grown either in borders or on rockwork. A white-flowered variety of it is very common in gardens. At Kew Gardens an immense bed of the blue and the white forms intermixed had a very fine effect. Multiplied by sowing the seed or by division. Found in the mountain regions of

Central, Southern and Eastern Europe, also in the Caucasus and Asia Minor.

*G. PNEUMONANTHE*, L. (*Pneumonanthe vulgaris*, Schmidt).—Stems erect, slender, 8 inches to 10 inches high. Leaves all on the stem, opposite, narrowly linear. Flowers large, of an intense blue colour and borne in terminal spikes. Blooms from August to October. This fine species requires a cool, spongy, deep soil rich in humus. It dislikes lime and prefers sandy ground. It does remarkably well when planted on the margin of ponds or brooks. Multiplied by sowing the seed or by division. Native of marshy places in the mountain regions of Europe and the Caucasus.

*G. AFFINIS* (Griseb.).—This is closely allied to the preceding species, from which it is distinguished by the oblong-obovate shape of its lower leaves and the lanceolate-acute form of the upper ones, which are wrinkled at the edges; also by its flowers being produced in fuller cymes and having narrower lobes and free anthers (in *G. Pneumonanthe* the anthers are connivent). Found in the Rocky Mountains, mountain regions of Hudson's Bay, &c., in N. America. Culture as for *G. Pneumonanthe*.

*G. SAFONARIA*, L. (*G. Catesbæi*, Walt.).—Stem erect, 12 inches to 14 inches high. Radical leaves lanceolate-oval, narrowed at the base; stem leaves narrow. Flowers almost sessile and borne in a terminal spike. Corolla of a light blue colour, with five erect, short, broad lobes, which are ciliated at the base. Blooms in October and November. Native of the United States of America and Canada. Culture as for *G. Pneumonanthe*.

*G. SPECTRUM* (Griseb.).—A tall-growing species with an erect stem from 3 feet to over 4½ feet high. Leaves lanceolate-oblong, 2 inches to 2½ inches long, seven-veined, opposite and disposed along the stem in the same manner as the leaves of *G. lutea*. Flowers borne in axillary clusters of two or three flowers on the whole of the upper half of the stem. Corolla blue, with broadly oval lobes. Blooms in August and September. Found in Vancouver's Island, in the west of N. America. This species is very rarely met with in cultivation. Culture as for *G. lutea*, except that it requires a half-shady position and a rather peaty soil.

*G. SEPTEMFIDA* (Pall.).—Stem slight and slender, 8 inches to 12 inches high, plentifully furnished with opposite, oval-obtuse, five-veined leaves of a dark green colour. Flowers large, borne in a terminal cluster. Corolla dark blue, with five oval-acute lobes, which are ciliated at the base. Blooms from July to October. Native of the alpine and sub-alpine regions of the Caucasus and the mountains of Western and Northern Asia at an altitude of 1000 metres to 3000 metres. An excellent garden plant, requiring the same culture as *G. lutea*. The varieties of it which are known as *cordifolia* (Koch), *glomerata* (Rgl.), and *latifolia* (Rgl.) are also in cultivation.

*G. WALDEJEWI* (Rgl. and Schmalh.).—Stem prostrate at first, then rising erect, 4 inches to 6 inches high. Radical leaves numerous, leathery, lanceolate, five to seven-veined, and 4 inches to nearly 6 inches long, by four-fifths of an inch to 1½ inches broad. Flowers white, borne in terminal branching spikes. Corolla 2 inches or less in length with a cylindrical tube and five lanceolate-elliptical acute lobes, which are longer than broad, and dotted with yellow or green on the inside. Blooms from July to September. Found on the mountains of Turkestan at an altitude of 1000 metres to 3000 metres. Culture as for *G. lutea*.

#### GROUP II.

*G. ACALIS* (L.).—The old *Gentiana acalis* of Linnaeus no longer exists, botanically speaking. First, Villars, and, after him, Perrier and Sonceon broke it up, stripped it bare, and abolished it. But it will be a very difficult matter to banish the name from horticultural catalogues, and for that reason I persist in giving it to that garden variety which is so plentifully grown in England under the name of *Gentianella*.

Take one of these English *Gentianellas* and examine it well; then compare it with the different forms under which *Gentiana acalis* is found in the wild state, and you will have great difficulty in seeing any resemblance between them. The *Gentianella* appears to come near (but only in a general way) the *Gentiana angustifolia* of Villars, which is grown in the flower-beds of the Grande-Chartreuse. It is a plant which, in the course of ages of garden culture, has undergone somewhat considerable modifications. Its flowers are now not absolutely stemless, but are borne on erect stems 4 inches to 6 inches high; its leaves are thick and broadly spatulate in shape, and its root-stock is stoloniferous to such a degree, that the plant has to be cut back every year to keep it from growing beyond the margins of flower-beds, to which it forms an edging, and invading the adjacent ground or walks. This, it must be understood, is what occurs in English gardens. In Mr. Robinson's garden at Gravetye Manor it has taken possession of whole grass plots, which it enameled in May and June with its superb blue flowers. Here, in France, it is easily grown by planting it in a compost of one-half humus or leaf-soil and one-half good vegetable mould, to which may be added a little sand. On rockwork, half or even fully exposed to the sun, it does wonderfully well, and, if care is taken to keep it free from wild or other plants of an encroaching character, it forms a valuable subject for planting on declivities or sloping ground, where its flowers are highly effective. It can be multiplied by means of offsets, but it is infinitely better to raise it from seed, and in doing this it should not be forgotten that the seeds of this group of *Gentians* are very tedious and, more especially, very capricious in germinating. I have sown seed of *Gentiana acalis*, some of which did not germinate for twelve months, while others (which, I must say, were more recently gathered) germinated in a few weeks. The seedlings should be potted off as soon as possible and while they are very young. They will commence to flower in about three years from the time of sowing, rarely sooner. As for *Gentiana angustifolia*, *G. alpina*, *G. Clusii*, *G. Kochiana*, and *G. dinarica*, which are differentiated forms of the old *Gentiana acalis*, they behave differently under cultivation, although all of them lend themselves, more or less, to the treatment mentioned above. The most difficult species to raise from seed and acclimatise is *G. Kochiana*, on account of the dislike which it has for lime. If the water with which it is watered contains any lime, this will either kill the plant or cause it to flag. However, the flowers of this species are the least attractive of all in their colour. In Belgium, England, and on the western coasts of France it succeeds pretty well.

The *Gentianella* is quite acclimatized in England, where it has modified its mode of life as well as its habit of growth, and withstands wonderfully well the damp, cold climate of the neighbourhood of London, where plants of its congeners, which have been imported from Switzerland or have been raised from seed, are grown with great difficulty under the same conditions. On the other hand, this plant has become anglicised to such a degree, that it cannot be grown on the Continent without a great deal of trouble; whereas plants raised from seeds of the alpine species succeed much better there.

The original *G. acalis* now presents four or even five well-marked species, viz. :—

I. *GENTIANA ANGUSTIFOLIA*, Vill. (not Michx.).—A stoloniferous plant, emitting underground ramifications. Leaves linear-oblong, narrowing towards the base for a considerable length, and glistening on the upper surface. Divisions of calyx more or less spreading, oval, and abruptly contracted at the base. Flowers large, very handsome, of a fine deep sky-blue colour, and spotted on the throat with sprightly green. This is the handsomest species of the whole genus. It flowers in May and June, and is found on rocky

and calcareous parts of the Alps at an altitude of 1000 mètres to 2000 mètres.

2. *G. CLUSII* (Perr. and Song.).—This is distinguished by its lanceolate-acute, leathery leaves and by the lanceolate divisions of the calyx, which are pressed close against the corolla, are not contracted at the base, and are separated by acute sinuses. The flowers are of a fine dark blue colour and have no green spots on the throat. The plant blooms in May and June, and is found on calcareous rocks of the Alps and the Jura range at an altitude of 1500 mètres to 2000 mètres.

3. *G. KOCHIANA* (Perr. and Song.).—Leaves large, flat, thin, spreading, oval or broadly oblong, and of a light green colour. Divisions of calyx oblong, limp, more or less contracted at the base, and separated by truncate sinuses. Flowers of a violet-blue colour, marked on the throat with five spots of a blackish green colour. Blooms in May and June. Common in pastures on the granitic Alps.

4. *G. ALPINA* (Vill.).—Leaves small, of a sprightly green colour, glistening, curving inwards and imbricated, forming rosettes which incurve at about the middle part of their length. Stem almost wanting. Root-stock very stoloniferous. Flowers of a dark blue colour, smaller than those of the preceding species. Blooms in May and June. Found on the granitic Alps at an altitude of 2000 mètres to 3000 mètres; also on the Pyrenees and the Sierra Nevada. The two last-named species require a compost of one-third crushed granite, one-third heath soil, and one-third vegetable loam, and should be planted on rockwork half exposed to the sun.

5. *G. DINARICA* (Beck.).—This is a form of *G. acaulis* with broad, thick leaves and erect, slender, almost cylindrical flowers of a dark blue colour. Found on the Alps of Southern and Eastern Austria.

#### GROUP III.

*G. VERNA* (L.).—A dwarf, caespitose plant, with leaves gathered into rosettes. Leaves elliptical or lanceolate in shape, of a bright green colour, and turning red in autumn. Flowers of a bright sky-blue colour, white at the throat, and borne singly on short stems. Blooms from April to June. Found in the mountainous and sub-alpine regions of calcareous mountain-ranges in Central and Southern Europe and in the Caucasus. This is a very pretty little spring-flowering plant, which grows very well on rockwork or on sloping ground fully exposed to the sun, and is also used for edgings. It requires a calcareous soil rich in humus. We grow it here in a compost of one-third leaf-soil, one-third heath-soil, and one-third vegetable mould. There is a fine white-flowered variety, and another with flowers of a very dark blue colour. There is hardly any use in trying to multiply this species by dividing the tufts, as almost every attempt which has hitherto been made to do so has proved ineffectual. The only sure method is by sowing the seed either in autumn or early in spring. If the seed is fresh it soon germinates, but if it is not, one has sometimes to wait for twelve months before the seedlings make their appearance. *G. verna* often flowers again in the autumn. On the higher Alps, that is, at an altitude of more than 2000 mètres, instead of *G. verna* we find *G. brachyphylla* (Vill.), which ascends to a height of 3000 mètres above the sea-level, but grows only in granitic soils. This species is distinguished by its short, oval-rounded leaves, which are of a glaucous green colour, and thicker than those of *G. verna*; but more especially by the tube of the corolla being much more slender than it is in that species. Rockwork; in a compost of heath-soil, finely-crushed granite, and vegetable mould, and in a position fully exposed to the sun.

*G. ANGULOSA* (Bieb.).—Found on the Alps of Austria, the Carpathian Mountains, the Balkan range, Mount Scardo in Macedonia, the Caucasus, and the mountains of Asia Minor. This species is distinguished from *G. verna* chiefly by its larger

flowers and by having the angles of the calyx more broadly winged. Culture as for *G. verna*.

*G. PUMILA* (Jacq.).—A native of the Tyrolean and Carinthian Alps, where it is found at an altitude of 2000 mètres to 3000 mètres. This is a very dwarf species with almost linear but thick leaves, forming compact rosettes, bearing almost sessile flowers, the corolla of which is deeply divided into five acute lobes, and is of a dark blue colour with a white throat. Blooms in June and July.

*G. IMBRICATA* (Frœl.).—Found on the lofty ridges of the Eastern and granitic Alps, at an altitude of 2000 mètres to 3000 mètres. Leaves oval-rounded, closely crowded together, and imbricated. Flowers large, of a sky-blue colour, and borne on leafy stems 2 inches or less in height. Blooms in June and July. The plant forms handsome, compact, turf-like tufts of foliage.

*G. BAVARICA* (L.).—The finest species of this group of Gentians. A small, dwarf, tufted plant, with oval-oblong glistening leaves of a light green colour borne on numerous sterile branches, which are crowded closely together, and on branches bearing at their extremity a flower-stem 2 inches or 3 inches long. Flowers comparatively large, of a fine, bright, very pure sky-blue colour, and with a white throat; corolla divided into five lanceolate-oval lobes. Blooms from May to August. Found in elevated parts of the Alps at an altitude of 2000 mètres to 3000 mètres above the sea-level, and always in moist, cool, peaty spots in pastures or in stony places.

The last two species require a soil that is peaty or, at the very least, porous and cool, well drained, and capable of retaining an abundant supply of moisture, although it may be fully exposed to the sun. In the alpine garden here we grow them in pure Sphagnum Moss on a wall facing due south, but the plants which we raise for sale are grown in pots in a compost of Sphagnum, heath soil and sand.

*G. PYRENAICA* (L.).—A very singular and handsome species, growing 2 inches or less high, and forming a small tuft of numerous narrow leaves of a dark green colour. Flowers of an azure-blue colour, greenish on the outside, pure white at the throat, and divided into five oval lobes, separated from one another by a triangular appendage, which is toothed at the edges. Blooms in May and June. Culture as for *G. verna*.

*G. OREGANA* (Engelm.).—A dwarf, caespitose plant, with oval leaves and numerous large flowers of a fine blue colour, growing in clusters at the extremity of stems 4 inches to 8 inches high. Blooms in July and August. Culture as for *G. verna*.

*G. ORNATA* (Wall.).—Found in the alpine regions of the Himalayas. A small dwarf plant with linear-obtuse leaves and solitary sessile flowers of a fine blue colour, and borne on stems 2 inches or less in height.

In addition to the foregoing, there are some other species belonging to this group, natives of the Himalayas or other parts of the world, but those which I have just enumerated and briefly described will be amply sufficient for the majority of amateurs, and I may add that the omitted species are very little grown by anyone.

#### GROUP IV.

*G. PURPUREA* (L.).—A very curious and strikingly singular species. Stem rigid and erect, 6 inches to 20 inches in height. Leaves narrow, lanceolate-oblong, very much veined, glistening, and of a dark green colour. Flowers large, erect, borne in a terminal head and in axillary clusters at the upper part of the stem, thus forming a thick and closely-set spike; they are of a very dark brownish-red colour and emit a very agreeable scent. Blooms in August and September. Found in pastures on the granitic Alps, the Central Apennines, and the alpine regions of the Carpathian Mountains; also on the mountains of Norway. This is a difficult plant to grow. In

our unfavourably dry climate here at Geneva we succeed in growing it in a compost of Sphagnum and heath soil, but, as in the case of *Gentiana lutea*, we have to be very careful not to break or injure the roots of the young plants, as any injury of this kind affects the plant to such a degree, that its death almost inevitably follows.

*G. PUNCTATA* (L.).—Found in the alpine region of the Alps, Carpathian Mountains, and Balkan range. It differs from the preceding species in having yellow flowers spotted with purple, elliptical leaves, and a campanulate calyx with nearly equal divisions (the calyx of *G. purpurea* being divided to its base on one side only like a spathe). Same culture. On the Pyrenees, instead of these two species, we find *G. Burseri* (De C.), which has large, erect, yellow flowers dotted on the inside; and on the Carpathian Mountains and the Austrian Alps we find *G. pannonica* (Scop.), which has dark red flowers dotted with black. Both these last-named species have the same habit of growth and the same form of inflorescence as *G. purpurea*, and are cultivated in the same manner. *Gentiana Charpentieri* (Thom.), *G. Gaudiana* (Thom.), and *G. Thomasi* (Gilab.) are hybrids from *G. purpurea*, *G. punctata*, and *G. lutea*, and are all cultivated in the same manner.

*G. FRÆLICHII* (Jan.).—Found on the Alps of Carniola and Carinthia at an altitude of 1800 mètres to 2500 mètres, and *G. frigida* (Hænicke), found on the granitic formation in Styria at an altitude of 1800 mètres to 2800 mètres, are two species with erect stems 4 inches to 8 inches high, bearing one or two large, erect, campanulate flowers of a pale yellowish blue in the first-named species, and of a greenish white with bluish reflections on the outside in the last-named species. In *G. Frœlichii* the leaves are narrowly-lanceolate, almost linear, while in *G. frigida* they are broader and very long. These species are easily grown on rockwork in a compost of one-third Sphagnum one-third heath soil, and one-third good vegetable mould, in a position half exposed to the sun.

*G. CILIATA* (L.).—This is one of the handsomest of the species that grow upon our mountains. Its flowers, which are of a pale sky-blue colour and appear in autumn, are among the treasures which we love to bring home with us in our autumn rambles. But the plant is a frightfully difficult one to grow, so that its culture is almost impossible. The seedlings of it which we have raised in the alpine garden here have only yielded flowers in the proportion of hardly 3 per cent. A heavy, compact soil, which is almost clayey, and full exposure to the sun are the conditions which appear to suit it.

In the course of last year we received seeds of a certain number of New Zealand and Australian Gentians, only one of which (*G. saxosa*, Forst.) has flowered. The other species appear to be of very slow growth. *Gentiana saxosa* is a very handsome little species with spatulate leaves, disposed in rosettes and of a fine cheerful green colour. The plant appears to come near *G. acaulis*. The flowers are numerous, white and borne in terminal umbels of four or five flowers; corolla divided into five oblong-lanceolate lobes. Blooms from June to August. It is a somewhat delicate species, requiring some protection during the winter in our climate. Our New Zealand correspondent who sent us the seed of these Gentians stated that all of them should be hardy at Geneva, but up to the present this appears to be doubtful. Next year, however, their behaviour will convince us one way or the other.—H. CORREYON, in *Revue Horticole*.

*Senecio Heritieri*.—This tender plant is growing out of doors at Offington, Sussex, but will probably require protection during winter. The plant under notice is a very handsome specimen. The leaves in shape and size resemble those of a Ribes, but are covered on the underside with a silvery pubescence. The flowers are arranged in large umbellate cymes and remind

one of *Cineraria*, the ray florets being white tipped with pale mauve and the disc florets deep purple with yellow anthers.—M.

#### JULY IN SOUTH DEVON.

DURING July rain has fallen to the amount of 2.73 inches on twelve days against 4.18 inches on nineteen days in the corresponding month of last year, the average fall for the last nineteen years being 2.80 inches. For the first seven months of the year the fall has amounted to 14.14 inches against 19.19 inches in 1894 and 14.04 inches in 1893. As regards sunshine, the month has not reached the average for July, which is 183 hours, 179 hours 10 minutes having been recorded, but the record for July, 1894, has been beaten by about 20 hours. From January 1 to August 1 1242 hours 30 minutes sunshine have been registered as compared with 1051 hours 40 minutes in 1894 and 1352 hours 40 minutes in 1893.

The mean average temperature 60.2° was 1.1° below the mean average for the last nineteen years. The lowest reading on the grass was 45° on the 5th, the highest in the screen being 70.7° on the 28th.

July was a more windy month than April, May or June, the total horizontal movement of the wind being 7433 miles, an average daily velocity of 239.8 miles. The greatest hourly velocity was recorded between 2 and 3 a.m. on the 24th, when a speed of 25 miles per hour was reached. On twenty-five days the direction of the wind has been from south to west.

In the garden the Lilies have throughout the month displayed their varied beauties, a stately *L. giganteum* over 9 feet in height, with thirteen flowers, being for a time the chief centre of attraction. This is a Lily that is not commonly grown, probably owing in a great measure to the fact that the bulb expends itself in flowering and that three or four years elapse before the offsets reach a flowering size. When well grown it is a striking object, associating pleasingly with the graceful foliage of the slender Bamboos and Arundinarias, the shining green of the large heart-shaped lower leaves being only less effective than the long creamy blossoms with their claret-coloured internal stains, which blossoms have the additional charm of possessing a delicious fragrance resembling vanilla. *L. candidum* from its associations, apart from its chaste loveliness, appeals to the heart more closely than any of its sisters of the Lily bed. From children we have known it, growing by the Jasmine-covered cottage window, blossoming in lines on either side of the path that led to the grey old sundial in the rectory garden, or standing, an emblem of purity, by the head of a little grave in the village churchyard. During the past month this Lily of the painters and the poets has surpassed itself, blooming, except in cases where the new Lily disease has been imported, profusely, the display being more than usually lengthened owing to the absence of high winds and rain to mar the snowy petals. *L. excelsum* (testaceum), said to be a hybrid between *L. candidum* and *L. chalcedonicum*, has carried a wealth of its soft buff flowers. *L. pardalinum* and *L. canadense*, the former a week earlier in bloom, on slender stems have borne their spotted, pendent blossoms, which swayed to every stray zephyr that invaded their sheltered retreat, where *L. Humboldti* has made a superb picture, bearing on tall stems numerous large flowers of orange-yellow flecked with spots of purple, while in the shade the vermilion of *L. chalcedonicum*, the most brilliantly coloured Lily in existence, glowed from out a carpet of tufted Pansies.

Carnations have done well and have scarcely suffered at all from disease, one patch of white Cloves being a mass of bloom. *Tigridia lilacea*, *T. grandiflora*, *T. pavonia*, and *T. g. alba* have brightened a sunny border with their gorgeous, but short-lived blossoms, which in the brilliance of their hues and fanciful mottling remind one rather of the floral display of the tropics than of the less emphatic colouring of the denizens of the English flower garden. A breadth of *Salvia patens* has clothed a broad bank with vivid blue which

breaks along the edge into the grey foam of *Gypsophila paniculata*—flower-lace it is called by some. I saw the other day a very pretty combination for table decoration consisting of sprays of *Salvia patens*, yellow Paris Daisies, and *Gypsophila*. The blue and yellow formed a charming contrast, while the fairy-like tracery of *Gypsophila* gave a grace of form to the composition that even Maiden-hair would not have rivalled. The Chimney Campanulas (*C. pyramidalis*) have thrown up tall spires of bloom, both purple and white, some 5 feet high, one plant being of a lovely faint lavender colour. With these the dark coloured herbaceous Phloxes make a striking contrast, *Galega officinalis alba*, a mass of white Pea-like blossoms, being also effective at the back of the border. *Telekia speciosa* I am rather disappointed with, and think that it might with advantage be relegated to the wild garden, where it would doubtless be effective. *Oenothera Youngi* and the Welsh Poppy (*Meconopsis cambrica*) have both filled their respective sites with bright yellow through the month, while amongst the annuals *Coreopsis lanceolata* and *C. sanguinea* contrasted their gold and brown with the dazzling scarlet of the Zinnias. All the plants of the beautiful *Coreopsis grandiflora* were lost during last winter, and the garden thus for this summer loses a valuable effect. The tuberous Begonias were perhaps never finer, and the drooping varieties having been carefully weeded out, show their bold flowers bravely. One of the most lovely flowers of the month, the *Salpiglossis*, has also flourished exceedingly, having produced in a slightly raised bed, over the verge of which fall the blossoms of the Ivy-leaved Geraniums *Mme. Crousse* and *Souvenir de C. Turner*, a profusion of many-tinted blooms wonderful in the arrangement of their colouring and reticulation. The Sweet Peas have been yielding baskets full of flowers daily, some of the newer kinds being especially decorative. Countess of Radnor, a bluish mauve, is one of the most effective. *Yucca filamentosa* on the rockery has thrown up flower-spikes of ivory-white bells that stand out well from the low-growing plants around. Handsome clumps of the Plume Poppy (*Bocconia cordata*) gave a new note of colour in the brownish yellow of their long panicles of inflorescence, and a large shrub of *Spiraea Lindleyana* has been a handsome object during its flowering season, though not so effective as its relative *S. ariaefolia* in general attractiveness, as its panicles of bloom are less freely produced and last a less time in perfection. In the wild garden the Lupines have been blooming a second time, and tall, 7-foot high spires of the Aconite have shot up amongst the perennial Sunflowers which have just commenced to expand their blossoms. Hollyhocks have been decidedly more successful this year than in previous seasons, and up to the present have shown but little sign of the disease that has of late years made their culture so difficult, no syringing with solutions of sulphide of potassium or permanganate of potash, which tend to keep the disease in check, having been necessary. *Arundo conspicua*, unharmed by the winter, has produced a large number of light waving plumes, and the glaucous foliage of *Funkia Sieboldi* has a pleasing effect in a partially open spot around which self-sown seedlings of blue Cornflower and the sweet-scented Tobacco plant (*Nicotiana affinis*) are now in bloom. On a high and almost perpendicular bank, clothed in the early spring with the blue of the lesser Periwinkle, large plants of *Clematis Jackmani* have intertwined their tendrils with the wiry stems of the former and are now a glow of rich purple on the green setting. The single white McCartney Rose that is planted against the pergola opened its first large and delicately fragrant blossoms on the last day of the month. The plant is in rude health, having braved the last winter without any protection, a proof that it does not possess the delicacy of constitution so often assigned to it. One note of regret must be sounded ere the chronicle of the month is complete. It is, that *Romneya Coulteri*, the pride of the garden in July, 1894, is no longer with us to delight us

with the purity and perfume of its large crêpe-like flowers. The loss of this splendid Californian Poppy is the severest blow that has been dealt us by the prolonged frost of last winter. S. W. F.

## GARDEN FLORA.

### PLATE 1028.

#### THE INDIAN OR SIKKIM YULAN.

(WITH A COLOURED PLATE OF MAGNOLIA CAMPBELLI.\*)

THE coloured plate is a faithful illustration of the rosy blossoms of this rare and beautiful Indian tree. The flowers were sent from the gardens at Fota Island, Cork, in April of the present year, and they gave one a foretaste of what may be expected when this noble species is more generally to be found amongst collections of flowering shrubs and trees. Fota is the residence of Mr. Smith Barry, who, together with Mr. Osborne (his gardener), is fond of rare and beautiful trees and shrubs of all kinds, and the noble masses of hardy Bamboos have long been a remarkable feature in that lovely and fertile domain. *Cordylina australis*, *Benthania fragifera*, New Zealand Flax and many other rare plants from New Zealand, North India and other temperate regions here (as at Tresco Abbey, in the Scilly Isles) find a congenial home, and the flowering there of this *Magnolia* marks an epoch in the calendar of successes achieved there. *Magnolia Campbelli* has long been known, its home being among the outer ranges of the Sikkim Himalayas, where it was seen by Sir Joseph Hooker and others fifty or sixty years ago. In its native forests it attains a height of from 50 feet to 150 feet, at an altitude of from 8000 feet to 10,000 feet, and as thus seen, covered with its great rosy white Water Lily-like flowers, its beauty quite defies description. The species was introduced to Europe in the year 1868, and perhaps the finest specimen is at Lakelands, near Cork, which has attained to the height of a small tree, being at least 40 feet or 50 feet in height. This specimen was planted by the late Mr. William Crawford and is about twenty-five years old; it was the first plant to blossom in our western gardens, and a figure and description may be found in the *Botanical Magazine*, t. 6793. The great blossoms are white inside, the outer petals being rosy, shaded with crimson behind, as shown in Mr. Moon's drawing. The blooms are, moreover, delicately fragrant, and, like all *Magnolia* flowers, are admirably adapted for cutting and arranging in bowls of water, care, of course, being taken to cut bursting buds or half-opened flowers only. The plants at Lakelands are in a sheltered position, surrounded by trees and planted in a deep rich soil. I have also seen specimens elsewhere in Ireland, viz., at Castlewellan, Kilmacurragh, and it exists also at Kew and in other private and public gardens in England, but so far I believe that those growing at Lakelands and at Fota Island are the only plants that have hitherto blossomed. In sunny, woodland glades well sheltered this noble species might be expected to succeed along with its native congeners, the Sikkim *Rhododendra* and that most brilliant shrub *Embothrium coccineum* from S. America. So far as my own observations go, this species is perfectly hardy in sheltered, mild positions, but its flowers coming as they do early in the year are very apt to get scathed or browned by early spring frosts and winds. In a young state the plant grows most

\* DRAWN FOR THE GARDEN by H. G. MOON from flowers sent from Fota, Cork, April 6, 1895. Lithographed and printed by Guillaume Severeys.

luxuriantly, and its leaves are so large as to produce quite a sub-tropical effect. In some cases it might be advisable to confine its roots in a limited space, as is now and then done with Fig trees or Bougainvilleas, so as to restrict its growth, and thus induce harder wood and possibly earlier flowering.

Mr. Osborne, gardener at Fota, sends the following notes regarding the flowering of this handsome Magnolia:—

This lovely Sikkim Magnolia is now in full flower (April 6) for the first time, although it has been planted here for many years and reached the height of 25 feet. It is planted in a nook sheltered from the north and east winds. The flowers, like those of other Magnolias, are terminal, the points of all main branches and every side twig being crowned with one large, slightly sweet-scented flower, which is from 6 inches to 8 inches in diameter. The colour of the outside of the flower is dark rose or crimson and lighter inside, with petals of great substance. I attribute its free flowering to the abnormally dry summer here of 1894. I say here because most other parts of the British Isles were suffering from too much rain, whilst all crops here were suffering from the want of it.

F. W. B.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**EARLY MUSHROOMS.**—The time has come for all those who desire Mushrooms, say at the beginning of November, to prepare the manure for making the first bed. Novices often err in using manure from grass-fed horses, such being of little use compared with that from corn-fed animals. See that the material is not thrown into a heap as collected, but spread out somewhat thinly in an open shed, where it can be turned over occasionally in order that it may partially dry and sweeten. When thrown together carelessly it often heats unduly before it is noticed. A large bed is not necessary for a start; therefore if droppings are scarce the compartment may be halved by placing a piece of board across it. When sufficient manure has been collected let it be thrown into a heap and allowed to remain undisturbed for a few days, after which it should be turned over every morning, always allowing the outside portions to come into the middle of the heap. When this treatment has dispelled the bulk of the steam, let it once more be mounded up and allowed to stand untouched for several days, when it may be wheeled in to form the bed. If it be found impossible to procure sufficient droppings by the required time, a fourth part dry Oak or Beech leaves may be added, also a barrow-load or so of sweet rough loam. Deep beds are not necessary so early in the season, shallow ones retaining sufficient heat even without the aid of fire-heat until the young Mushrooms appear, when a gentle warmth may be allowed in the hot-water pipes. In making the bed, do not throw on too much stuff at a time, or thorough firmness cannot be secured. If there is sufficient head-room for working, nothing beats treading the bed in the first place, beating it firmly with the back of a five-tined fork afterwards. The making completed, those who do not possess a bottom-heat thermometer must thrust in a testing stick. This must be examined occasionally, and when it is found that the heat has risen to its maximum, a quantity of fine soil, preferably loamy, should be prepared for surfacing. When the heat has declined to about 90°, spawning may take place, there being no fear in these first early shallow beds of any reaction. If spawned at this figure and immediately soiled down, the heat is preserved; whereas if a fall to 80° is allowed before spawning, the bed will frequently run down to 60°, and a considerable time elapse before young Mushrooms appear. After soiling and firming with the back of a spade, using a little warm water if it is at all dry, cover the bed with a moderate thickness of Oat straw if procurable, this being far better than

hay refuse, which is so apt to become mouldy and smell, making the surface actually colder than if it were not covered at all. As no fire-heat will be necessary for a time, so neither will floor and wall dampings, these being commenced as soon as the pipes are warmed and a less moist atmosphere prevails. To insert the spawn I always use a flat-ended dibber; a sharp-pointed one is apt to leave a cavity under the spawn after it is pushed in. Some use no tool, but simply make a small hole 1½ inches deep with the hand and push in the spawn, which should be in pieces about the size of a pigeon's egg. Re-beating the surface is necessary when spawning is completed. It is a good plan to place the spawn in a box a few days before it is wanted and to subject it to the moist atmosphere of a stove or forcing house; it then breaks easily and operates sooner when put into the warm bed. I have known a few good early Mushrooms secured by breaking up, levelling and watering the soil of an old bed in the

The Willow Gentian (*G. asclepiadea*). (See p. 140.)

Melon house and inserting the spawn, afterwards covering with cross bars and mats or loose straw material, but this cannot of course be done where the house is required for young plants for winter. Amateurs who have only a Melon or Cucumber frameway, after the fruit is cut, employ the same means to secure a few Mushrooms, furnishing extra bottom-heat by building up a lining of stable manure round the sides and ends of the frame.

**WINTER CUCUMBERS.**—It is now high time seed was sown to produce plants for yielding fruit during November and December. Some people prefer to sow a little later, but I think this is an evil, as if the plants, owing to fine weather and extra strong growth, should come into bearing a little sooner than is required, the fruit can easily be picked off in infancy and the plants allowed to strengthen themselves against the trying ordeal of winter cropping. Sion House or a good strain of the old Telegraph cannot be beaten for winter work, and the seed should be sown in small pots, not many seeds in one, and the plants afterwards potted off. Give them a light airy position near the roof glass, where red spider does not abound, as once get this pest on to the foliage of young winter Cucumbers they might as well be thrown away. If

the house in which they are to fruit has had summer Cucumbers or Melons growing in it, a thorough cleansing must be given, well washing all woodwork with warm soapy water and coating the walls with lime-wash into which a little sulphur has been stirred. This last ingredient is important, as it not only aids in keeping spider in check, but also creates a healthy atmosphere. Plants which are now cropping and are to keep up a supply until the winter fruiters commence to bear must be well looked after, and as the summer declines the demand for salad will be lessened. These plants should be allowed to carry a moderate quantity of fruit only, and receive a good, rich top-dressing of loam and manure, followed by occasional drenchings of farmyard liquid. The seed for a batch of plants to fruit in January and February may be sown about the middle of September.

**SALADING.**—If seed of various kinds of Lettuce, including the small, tender Cabbage variety All the Year Round, was sown three weeks ago as recommended, the plants will soon be fit for transplanting. These will afford a good supply from the end of October and through November, the secondary sowings making nice plants if well treated for putting into any spare frames or pits for winter protection. Give plenty of room to these late batches, as the more stocky the plants grow the better will they stand keen frost. When huddled together they become weakly and soft in growth, and are afterwards easily damaged by frost and wet. The present is a good time to make a sowing for plants to stand the winter in a small state, to be pricked out under sheltered walls and warm corners, and also for wintering in frames for transplanting in February. A second sowing for this purpose should be made the first week in September, especially in more southerly counties, as should the autumn be sunny and warm the first sown lot will sometimes get too large for the purpose. Nothing surpasses the old Brown Cos for hardiness and general excellence in spring. Where a Cabbage Lettuce is needed for spring use Daniels' Continuity may be sown with the above sort, this standing frost and wet better than most Cabbage varieties. It is, moreover, very crisp and juicy. The first sowing of Endive will now have produced plants fit for thinning out. Let this be done with a free hand, as nothing tends so much to weaken the seedlings as neglect in this matter.

If another sowing is made now it will prevent the possibility of a blank in this salad in spring should the first raised batch run to seed. I would confine myself to the Batavian only at this sowing.

**CARDOONS.**—The earliest transplanted of these will now be advanced in growth, and will need feeding to promote sturdy, well-developed heads. These are very free-rooting when healthy, and need abundant supplies of moisture, ordinary rains being quite insufficient for their wants. Go over the plants and remove any suckers that have started from the base and any rough, discoloured leaves, giving a couple of drenchings with farmyard liquid at intervals of a fortnight; or where this is not procurable, dress with guano, fish manure, or nitrate of soda, strict moderation being necessary in the case of the last, afterwards watering the fertiliser home.

**FRENCH BEANS.**—Where time and labour can

be spared, the present is a good time to sow seed of some early growing variety for planting out in a frame for late picking. It will be best to sow in small pots, placing these in a fairly warm house until the plants are an inch high, when a cool frame and night protection will rapidly bring them to a fit size for transplanting. Let the compost be fairly rich, mixing some Mushroom manure with it, and allowing plenty of room between the plants. A little later on, say at the end of September, linings may be built up round the frame to afford the plants sufficient heat, and nightly covering with mats or bracken practised. Thus a supply of young tender pods may be had until sharp frost sets in. Late open-air sowings still in a young state should soon have a rough framework erected over and around them in order that on the approach of colder nights protection may be given.

**HARDY GREEN COLEWORT.**—This must not be confounded with the ordinary Rosette form, being quite distinct and if anything more hardy, which is saying a good deal. If a sowing is made now, it will afford plants for yielding a capital lot of green heads in early spring after the Rosette form has been used. Any spare piece of ground from which late summer crops have been cleared will answer, no digging or preparation being necessary. Plant from a foot to 15 inches apart always, and until the plants become established, stir the ground between the rows with a five-tined fork and give a good dressing of artificial manure, to be washed in by the winter rains. Let the planting out of successional batches of the Rosette Colewort be proceeded with as soon as the plants are ready, nothing repaying care and labour better than this winter vegetable. Ordinary spring Cabbages for pieking into frames may now be sown, this being quite early enough if ungainly size and failure after lifting in spring are to be prevented.

**VEGETABLE MARROWS.**—On healthy plants fruit should now be plentiful, that is, where cutting has been regular. When fruit is allowed to grow to a large size and mature on the plants, much of the vitality is lost and the quality of that cut for cooking affected. Those whose custom it is to grow Marrows on heaps of rank manure will this season have found out that it is not a good plan, as the amount of sunshine has been insufficient to consolidate growth; hence continuous grossness and barrenness have been the result, most of the fruit which did set turning yellow and falling off. Where fruiting plants have only a limited quantity of soil to root into, the watering-pot must be kept in use, as it is quite surprising how much root moisture Marrows will take; nothing surpasses farmyard liquid. Pen-y-byd (a small, round Marrow) is a capital kind, especially for late use. When cut in quite a young state its flavour is delicious.

**CARROTS.**—Where young tender roots are in constant demand, another sowing of any of the Horn varieties may now be made, affording a warm, sheltered border and fairly rich soil. Use plenty of soot or wood ashes when preparing the bed, as wireworms are often more troublesome amongst autumn-sown Carrots than spring ones. The roots from this sowing should be fit for drawing by the middle of November, and as growth after that date will be slow, they will be useful for soups and flavouring right through the winter, being allowed to remain in the soil and protected during sharp weather by loose bracken. If the ground is wanted for other purposes, Turnip-rooted Beet sown for early use may now be lifted and stored away in a very cool place—say behind a north wall. If laid in and covered with fine soil it will keep sound and plump for a long time.

J. CRAWFORD.

#### FRUIT HOUSES.

**POT VINES.**—The plants intended for early fruiting next season will now require more air and thorough ripening of the canes if required for early forcing. Growth being finished, more air and less moisture will be beneficial, and any

shortening of the canes may now be done, keeping the plants on the dry side for a few days after the cutting down. If the Vines are well developed and the wood of a nice brown colour fire heat may be dispensed with, though I do not advise placing the canes in the open for a little time, as we often get much rain at this season, causing a late growth. If the canes can be given glass shelter and freely exposed with top and bottom air, there will be less difficulty in ripening up the wood. Late growth may be assisted by fire-heat and plenty of ventilation at the same time, but to promote early ripening and to assist the growth to mature it is well to cease feeding. Sufficient moisture both at the roots and tops should be given to aid the plants in swelling up the buds for next season's fruiting. With canes in good condition less moisture will be required, but there should be no stint, and the plants treated thus will be in condition to place on a hard coal ash bottom under a wall in the open early in September, where they will get full sunshine, the canes being firmly secured to prevent twisting. In case of very wet weather it is advisable to place slates or boards over the pots to throw off excessive moisture. Young plants struck from eyes this season for cutting back next year will be growing freely, and will need generous treatment for a few weeks longer, giving liquid manure if the pots are full of roots and a warm temperature, syringing daily. This treatment should be continued till the end of September, when more air and less moisture will be necessary. It is not advisable to repot after this date, as there is not time for the plants to fill the pots with roots.

**EARLY PERMANENT VINES.**—The work in this department since the crop was cleared has not been great, but with much sun, unless the rods were kept well syringed there will have been trouble with red spider and other pests. I do not intend to convey that the canes must be kept growing freely. Strong lateral growth after a certain period with early-forced Vines is not desirable, and by retaining the fully-developed foliage to absorb the sap, late growth is not encouraged, though the roots are fairly active. With a sudden change in the weather overhead syringing will not be necessary, and there should be no complaints of unripened wood. Now is the time for abundant ventilation, and the opportunity may now be taken to renew boilers which are defective and in a measure prepare for next year's forcing. Of course, to summer-fruiting Vines these remarks are not applicable, as fire-heat may be necessary for the next few weeks to ripen up the wood, at the same time giving all the air possible. Early Vines cleared of their crop some little time may now be assisted in maturing lateral growth by shortening back the shoots to about two thirds of their length; this will ripen up the back buds and allow more sunlight to enter the house. The same remarks apply to the terminal growths, which may have been allowed to grow freely. In wet weather it is well to draw up the sashes to prevent inside borders getting too much moisture, also to maintain a dry atmosphere. Should the borders be inside and out it is a good plan to cover the portion outside to throw off heavy rains. Though too much moisture tends to late growth there should be no drying of roots. To keep these moist it is a good plan to empty the tanks when there is a heavy rainfall; by doing this every few weeks the roots will be kept moist and active. Any Vines which may have got a touch of red spider or thrips may now be cleared of the pests by syringing, dressing with sulphur or tobacco water, and fumigating.

**LATE GRAPES.**—All late Grapes, no matter how long they require to be kept, should now be colouring freely, as bad finish means a lot of decay during the winter; good colour and finish give firm skin free of spot and disease. Hamburgs and Madresfield Court nearly ripe need every attention to keep the berries free of damp and spot. In rainy weather allow a free circulation of warmth through the pipes and give free ventilation also during cold nights. Do not allow the temperature to fall below 65°, at all times giving

top air if drip can be avoided. Such varieties as Gros Colman need a long period to ripen, the colouring being deficient if not given plenty of air, warmth and light. In the case of fruit just turning, the bunches should be gone over and berries pressing hard against each other, also any small or stoneless berries, cut out. Muscats require even more care if wanted to hang, and being most valued in midwinter should be well finished, giving a higher temperature than advised for black kinds. In no case should the foliage be dense, as this prevents the fruit taking on that rich amber colour so much liked. Much may be done now to give additional colour by tying back large leaves or laterals and exposing to the light and sun.

**RIPE GRAPES.**—With heavy rains there will be trouble in the way of cracking. Such varieties as Madresfield are very subject to crack, and the borders, if outside, should be covered without loss of time. I use corrugated zinc sheeting for the purpose, but any material may be used that will throw off heavy rains. It is well to place the material on rafters or supports not close down on the soil, as then air can reach the roots and growth is not arrested. Front air can always be admitted, and a chink on the back ventilators will maintain a free circulation, and in the case of the sashes running down over ripe bunches, temporary boards may be used so as to give air and yet exclude drip. I have used large sheets of rough glass on a few strips or supports, and by this means ventilation is always ample. In the case of ripe fruit the borders must not be kept too dry, as this causes shrivelling and does the roots much harm. A thorough watering should be given when absolutely necessary, doing the work early in the day so as to get the surface dry by nightfall. The surface-roots can be much better managed by giving a good mulch at the colouring period, this keeping the roots active. In light porous soils I have used partially dried cow manure as a mulch. The new roots soon lay hold of the cool manure. Means must also be taken to guard against wasps, which soon play sad havoc with ripe Grapes. If shading is used, let it be as thin as possible so as not to prevent free ventilation.

**TOP-DRESSING VINE BORDERS.**—In many cases it would be preferable to top-dress borders now instead of early in the year. By top-dressing I do not mean that large quantities of animal manure should be employed, but a portion of the old inert soil or manure should be removed and a layer of new material added. The fibrous roots will soon take to the new soil and push out in all directions. With Vines in a bad state and deficient of roots this surface-dressing is not advisable. For top-dressing, wood ashes, mortar rubble, and bones or bone-meal mixed with the soil are preferable to animal manures, and if the latter are used they should be in small quantities, or as a finish to the surface soil. New borders with recently planted Vines should not get too much moisture.

G. WYTHEN.

## ORCHARD AND FRUIT GARDEN.

### OPEN-AIR FIGS.

It would be interesting to learn how Fig trees generally growing out of doors stood the severe test of last January and February. Doubtless those growing in favoured counties, and which had been well looked after during the summer, would, with ordinary protection, by means of straw, bracken, or garden mats, survive the frost which came upon the none too well-ripened wood. What about trees which, in addition to having no particular summer thinning, were not laid in to the wall in autumn and received no winter protection at all? I am afraid such will have lared badly. Two trees growing in a cottager's garden near here, and which occasionally bore a few nice fruit, were killed almost to the ground line, only a weak, puny shoot show-

ing itself here and there this summer. I know that even in Fig counties some of the fine old trees, occupying sheltered sunny corners in kitchen gardens, and which bore profitable crops fifteen or twenty years ago, have not of late received so much attention, and have actually been left in winter to take care of themselves, gardeners thinking that the uncertainty of the crop, caused by unripened wood, did not pay for any extra trouble. If, however, any of these old Fig trees have perished, it will be matter for regret, as, independent of their ornamental and interesting character, their fruits, even though few in number, could not be equalled for flavour and lusciousness by any grown under glass. In planting Figs out of doors, two most important points to be observed are perfect drainage and a confined root run. Neglect this, and gross wood, barrenness, and consequent disappointment are sure to follow. Neither must a rich larder be provided, a medium loam and ordinary garden soil in equal quantities suiting them best, with a free admixture of old mortar rubble as a corrective. A south or west corner must be selected, and the roots kept within bounds for the first few years at any rate by slates or slabs, the same being cemented together, one or two cavities being left at the bottom for the escape of water. A bottom slate is necessary to prevent the descent of tap roots. The nearer the surface the bulk even of the fibrous roots is the better. Figs, like all other fruit trees, being prone to make more shoots than can be duly exposed to the influence of sunlight and air, should be early disbudded, midsummer and autumn laying in of the wood being indispensable. Nothing responds more quickly to a surface mulch of old Mushroom manure than the roots of a Fig, colonies of fresh fibres soon running into it, these being further benefited by a top-dressing each spring of loam and lime rubbish. Fig trees even now-a-days would, I am confident, yield fairly remunerative crops in the open air if more attention were paid to cultural details, especially to that most important one—judicious thinning of the wood.

At the end of November provision must be made for protecting the trees from frost, nothing answering so well as the common Bracken, covering this over with ordinary garden mats. This ought not to be removed all at once in spring, but piecemeal.

In my earlier days I have seen good fruit gathered from bush trees grown in warm, well-drained beds in open, sunny positions in Essex. Two of the best I ever saw were put into very large pots, these being plunged in the ground, a trench afterwards being dug round, the pots broken with hammers and the roots liberated after the trees had become fruitful. As I stated before in these columns, the finest Brunswick and Brown Turkey Figs I ever saw grew in the garden at Sherringham Hall, on the Cromer coast, in Norfolk. These fine old trees were not trained formally, but allowed to ramble across the wall border to the path, the elbowed shoots in some instances having rooted into the soil, forming, as it were, trees of themselves needing only detaching from the parent. East Anglia generally has long been noted for its fine old Fig trees, some of the best being in gardens around Bury St. Edmunds. Perhaps Mr. D. T. Fish can tell us what condition they are now in and what the crops are like this season.

Notts.

J. CRAWFORD.

**The Japanese Wineberry.**—This Bramble (*Rubus phœnicolasius*) is at present laden with fruit. The plant is very ornamental, the foliage being handsome and distinct, the lower sides of

the leaves almost white, much the colour of the undersides of the leafage of *Boceonia cordata*, while the branches are covered with a dark red pubescence, which extends to the exterior of the berry sheaths. This Wineberry is well worth growing for its attractive appearance alone, the sprays of fruit clusters with the individual fruits ranging in colour from the polished crimson of the ripe berries to the pale orange of those which the hairy red calyces have but just exposed being exceedingly decorative. The ripe fruit is much appreciated, its brisk flavour rendering it extremely pleasant to the palate. The other day I observed some of the fruit displayed for sale in a fruiterer's shop, and on inquiry found that it was selling readily and at a remunerative price, being preferred by many to Raspberries for dessert. The plant was introduced in 1877, but has not been widely cultivated. In my opinion it is well worth a trial both on account of its fruit and for its fine appearance. Here, the long shoots were killed by the last severe winter, but the bushes are now carrying a crop that quite puts the common Blackberry of the hedgerows into the shade.—S. W. F., *Torquay*.

**Pine Prince Albert.**—This variety is of more than ordinary merit, and next to the Queen would be hard to beat either for general appearance or quality. It belongs to the same class as Black Jamaica, having dark purple leaves, which grow closely together in an upright form, even the outer leaves spreading but little. The fruit is conical, averaging from ten to twelve pips deep on healthy plants, of a pleasing bronzy yellow colour, and carrying a very small, neat crown. It is useful for growing with the ordinary batch of summer Queens, as it ripens a little later and thus keeps up a succession. The fruit may be kept for some time after it is ripe without losing either its colour or flavour. It should be given the warmest and lightest end of the Pine pit, and enjoys rather more bottom-heat than the Queens.—C. H. N.

**Plum Dymond.**—We do not hear or read of this Plum so much as one might expect, considering what a prolific and useful variety it is. Its large size and colour are likewise much in its favour. Like many other Plums, it is liable to make strong, rampant growth if planted in rich deep soil, barrenness for many years resulting. What it requires is a soil rather poor than otherwise, with a surface mulch to prevent evaporation in hot, dry summers. It then yields abundantly, soon after planting, and continues to do so annually. It is a favourite Plum in this locality both amongst market growers and farmers. It is seen in its best form on a south wall, the fruit here swelling to an immense size and laying on a bloom of great depth and beauty. All who want a large good Plum for cooking should plant Dymond. It makes a delicious preserve.—J. C., *Newark*.

**Pear Jargonelle.**—I think it was Mr. Young who last year spoke of the advantage of a cool season for ripening this well-known Pear. This season seems to have suited its wants, judging by the heavy crops of extra fine fruit the trees hereabouts are bearing both on walls and espaliers. I think the latter form of training suits the Jargonelle best, as the fruit, while escaping the baking influence of the sun which wall fruit gets, yet receives sufficient to swell it to a large size and to develop its flavour. Fruit from sunny walls in hot summers is likely to ripen too hastily, and be in consequence void of flavour. As Mr. Young said in his note, the Jargonelle cannot be easily beaten as an autumn Pear, so many people disliking the musky flavour present in Williams' Bon Chrétien.—J. C., *Newark*.

**Planting out Pines.**—The planting out of Pines in beds of soil is not, I think, so much practised as formerly; still, it has much to recommend it, if one may judge by the splendid fruit annually grown by Mr. Gleeson at The Warren House, Stanmore, Middlesex. For years this grower has been noted for his fine Pines, both of the Queen and Cayenne seasons. Mr. Gleeson's plan is

to pot up the suckers in the usual way in autumn, and to transfer them to the bed of soil when well rooted the following spring. The bed is arranged in tiers, in form similar to the stage of a greenhouse, which prevents the water from running to the lower or front part of the bed, as would be the case were it built in an ordinary slanting position. The plants are allowed plenty of room and firmly rammed. As growth proceeds and roots become abundant, stimulants are given, a favourite manure with him being guano. In autumn, rest is induced by gradually withholding water from the roots and lowering the general temperature. One advantage of planted-out Pines over those grown in pots is that during the resting season the roots are not so liable to suffer from excessive dryness, the mass of soil, though unwatered, retaining sufficient moisture to preserve the roots in a plump condition. On the other hand, it is questionable if the plants will show fruit quite so early in spring as the pot ones, the confined condition of the latter inducing an early start after extra bottom-heat is applied. It may be thought that planting out incurs more labour, but this I question, as I think a balance is effected by the less amount of water needed by the plants growing in beds. I am not sure, but I think the fine Pines grown at Castle Hill, Devon, are from plants growing in beds of soil without pots.—J. C.

#### PLANTING FRUIT TREES.

THE heavy crops of Apples, Plums and other kinds of fruit this year appear to be inducing many to seriously think of planting fruit trees this autumn, and a great many inquiries have already been made as to where is the best place to purchase fruit trees. Such a question is more easily asked than answered, for the following reasons, viz., change of soil and situation. It is all very well to say to the inquirer, "get the trees from a firm of the highest repute." This is excellent advice, but something more is needed, as, for instance, whether they will succeed and rapidly develop into fruitful trees when bought from any particular firm and replanted again in the buyer's garden or fruit plantation. This should be ascertained prior to making any great expenditure, otherwise the results may prove very disappointing indeed, and the nurseryman or gardener receive unmerited blame. About nine years ago I had a quantity of fruit trees of different kinds from a well-known firm, and a fine, well-grown and fibrous-rooted lot they were, but none of them took properly to our soil and not one of them has done well. Many have had to be rooted out and replaced with others, yet trees from the same firm are a thorough success on land of a different character, which proves how careful we should be in selecting, more especially if fruit culture for commercial purposes is contemplated. My experience is that all fruit trees answer the best if planted in a soil of a somewhat similar nature to the one they have been accustomed to, and that soil distinctly opposite in character is best avoided. Another point of importance is the selection of the trees early in the season, and a little time and money spent now in visiting some of the best nurseries for that object will be amply repaid by having an early pick of all the finest trees. Those who order late have to put up with what the early purchaser has left, and though the trees may be only slightly inferior, they are not so uniformly good as those first ordered; not only so, but the order is executed at the earliest date possible that the trees can be moved with safety and before the great rush of orders flows in, which means in many cases more time to get up the trees properly and more care in packing, as the work has not to be performed so hurriedly as later on. In gardens where the supply of fruit is only required for

home consumption, a considerable variety is sometimes necessary to provide a supply of each kind for as long a period as possible, but for market the object is totally different, and I would strongly suggest a very limited number of sorts. What the market grower requires is fruit of large size, good appearance, and which will travel well, also varieties that are known to succeed and produce heavy crops freely in the immediate locality. By this means regular consignments in bulk of one or two sorts can be put on the market, and customers will be numerous for such produce.

Before planting any trees, however, it will be wise to see that the drainage of the land is

Group of *Gentiana acaulis*. (See p. 140.)

good, for many an orchard that would otherwise be a source of profit is rendered of little or no value by the bad drainage and crippled state of the roots, arising from the stagnant water remaining about them. It is, comparatively speaking, useless to manure or prune carefully water-logged trees, for if the roots are in a bad, wet, and cold condition, good results are practically impossible. Again, there is the insect question to be considered in purchasing fruit trees. Supposing Apple trees are infested with American blight, the buyer will have considerable trouble and some expense in extirpating this scourge; therefore it will be well to have as much proof as possible that the trees are, and have been, entirely free from that enemy, thus ensuring a clean start and avoiding increased expenditure. Black Currants should also be examined to see if they are troubled with mite; this may be easily detected by the abnormal size of the buds, many of which can be discovered on the bushes in a dead condition, having never started into growth last spring. Once get a stock of Black Currants infested with this bud mite, it will mean great perseverance and labour to conquer it, otherwise it will ruin the trees. W. G. C.

#### GOOD RASPBERRIES.

It is with some diffidence that I venture an opposite opinion to that of so excellent a judge and grower as Mr. Wythes. But my experience of Superlative Raspberry has put me on the side of Mr. F. Bedford rather than on his (p. 93). That Superlative is an extraordinary cropper and a large fruit of firm texture and extremely handsome appearance I freely admit. But here, I think, its distinctive merits end. It much surprises me that Mr. Wythes should speak of its flavour as brisk and acid. I consider that it is extremely deficient in that acidity which is necessary for the best tarts and the best preserve, and that it will not bear comparison with the old Red Antwerp (to make

that a standard) in this respect, although it is a pleasant fruit to eat fresh. Mine is a good natural Raspberry soil—the wild Raspberry abounding in the neighbourhood—and my plantation has received every possible attention in the way of preparation of the ground at first, keeping it firm and richly mulched, copiously watering in drought and so forth. A few years ago I was unwise enough (as I now think) to do away with the Red Antwerp, or a local variety of it, which before constituted my stock, and plant Superlative and Hornet. Of Hornet I will not now say more than this, that although a large, sweet, tender-fleshed fruit, it is not of full flavour and has not been a change for the

palier wires to be tied in, and the fruit on these has been most marked, being finer and more abundant than on canes of the older stools, quite as much finer as the fruit of one or two-year-old Strawberry runners is than that of older plants. Where it can easily be practised I believe the cultivation of the canes as annuals, or rather biennials, would be advantageous. Another point is this: that though a little—and it is but a little—is gained in size of fruit by shortening back the canes, much is lost in weight and duration of crop. Superlative, for example, will produce fine berries right up to the points of the canes if left full length.—G. H. ENGLEHEART.

— Mr. Wythes' experience and authority among fruits are so great, that it needs considerable courage to differ from him in these matters. Still I have no hesitation in placing Baumforth's Seedling several points ahead of Superlative or any other known Raspberry, and in declaring that were I limited to one variety, Baumforth's Seedling should be that one. I should also state that I have not grown Superlative to anything like the same extent as Baumforth's Seedling. But I have seen and tasted it in good condition in several localities, but not once equal in size, colour, flavour, and form to Baumforth's Seedling as grown for dessert and preserving in quantity by myself. I do not understand Mr. Wythes to say that Superlative matches Baumforth's Seedling in flavour. But if this very skilful grower really means this, one is tempted to slightly alter his pointed question to Mr. Bedford thus: "Has Mr. Wythes got the true Baumforth's Seedling, as I cannot agree with his comparisons as to flavour?" Mr. Wythes will also pardon me if I appropriate his parting eulogium over Super-

better. My espalier row of Superlative has this summer been a sight worth seeing for size of berry and weight of crop; indeed, I thought of having it photographed. But "the proof of the pudding is in the eating," and it would be well if we judged many of our handsome modern fruits and vegetables by this homely, but supreme standard. I now sorely miss the sharp rich flavour of my old Raspberry in all cooked states. The authorities of my household pronounce Superlative flat and dull in taste, and the preserve is dead in colour and full of very large seeds. Again, when I speak of the extraordinary cropping qualities of Superlative, I am not in agreement with Mr. Wythes as to the extent of time during which it yields a full crop. I own that it sometimes gives a sprinkling of very late fruit, but my old Antwerp gave a full crop over more weeks than Superlative does. Mr. Wythes quotes a first-class hardy fruit grower on behalf of Superlative. Last year I posted some sprays of enormous fruit to a fruit grower in the eastern counties who makes a speciality of Raspberries, and is a man of much knowledge and judgment. He replied that in his experience these long or thimble-shaped Raspberries were always deficient in flavour, and that he much preferred the round-berried kind he already grew.

I should like to add a word upon the cultivation of Raspberries. When lecturing, during the last three years, upon cottage gardening I have always advised the espalier method. This mode of culture I have advocated and practised myself, because it is tidy and economical of space. But I have now come to the conclusion that it is unscientific. It ties the stools down too long to the same ground. All plants which make their natural increase by stolons, runners, or similar "travelling" processes, are greedy of and greatly benefited by entirely fresh ground. I tried the experiment last year of leaving the strongest of the canes which had come up irregularly and too far from the es-

*Gentiana algida*.

palative and place it to the credit of Baumforth's Seedling thus: "If the long time it crops is taken into account, I consider it the very best Raspberry grown. Given good culture and not allowed to remain too long in one place, it makes grand growth and gives very fine fruit." If I might venture to add to this encomium, it would be to say that the growth, alike in the manner and the amount of it, in Baumforth's Seedling, and the fruit alike in bulk, character,

and quality are as near perfection as we have yet attained among Raspberries.—D. T. F.

— At p. 93 Mr. Wythes asks if I have Superlative true. There would be no excuse for having it otherwise, as it is distinct from all other Raspberries. I quite agree with Mr. Wythes that soil has much to do with the growth and flavour of fruits, and a dry root run increases acidity in other fruits than Raspberries. No doubt in a dry season like the present has been I have a great advantage over Mr. Wythes, as in the strong holding soil the drought was a blessing, and I had no occasion to resort to watering, which as a rule does more harm than good. Here this season Baumforth's Seedling was three days earlier than Superlative and both are still giving a good quantity of fruit. The superior flavour of Baumforth's here has been remarked by many.—F. BEDFORD, *Staffan*.

#### Fruit notes from The Hendre, Monmouth.

—A year or so ago reference was made to the new and unique fruit garden made at The Hendre, near Monmouth, by Mr. T. Coomber, the able gardener to Lord Llangattock. As then stated in THE GARDEN, the major portion is covered with fine-meshed wire netting, supported by strong iron columns, which effectually excludes birds and permits the fruit to be gathered at any time without the usual inconvenience experienced under ordinary nets. The soil is a heavy red loam, in which fruit trees of all kinds apparently succeed admirably. Strawberries, Mr. Coomber informed me, had been extra large and good, especially Noble. Currants were loaded with fruit, the best blacks being Lee's Prolific, Ogden's and Champion; amongst reds, Raby Castle, Grape and Dutch were remarkably fine; in white varieties, the White Dutch was the most prolific and best. Raspberries were really splendid, but I think Superlative was the best of all, for though not so sweet as some other varieties, it more than compensates for any lack of flavour by the heavy crop and enormous berries. As a rule Pears are not good in this portion of the west of England, but the popular proprietor of The Hendre has no cause for complaint, as most of the trees are producing fair average crops. Pitmaston Duchess, Marie Louise and many others are bearing heavy crops of fine fruit on the walls. Apples are particularly fine and well coloured; a few of the most conspicuous are Peasgood's Nonsuch, Frogmore Prolific, very large and highly coloured; Lane's Prince Albert, Ecklinville Seedling, Cox's Orange Pippin, Red Astrachan, Irish Peach, Lord Suffield and Cellini; each of these was producing excellent crops of clean and perfect fruit. Cherries grown as bush trees appeared in prime order proving how well some varieties will succeed in that form. Belle Magnifique and Morello were carrying fine crops of fruit; most of the other sorts had been cleared of their crops. In the houses devoted to fruit, Grapes were first-class, especially Black Hamburgh and Lady Downe's; Muscats had fair-sized bunches with large bold berries of good colour. Peaches in the late houses promised well for late supplies, but perhaps the best fruit on the place is the Pines. It is seldom one can see such magnificent plants and fruit; they alone will pay anyone interested to visit this well-managed and well-kept garden.—W. G. C.

**The Newtown Pippin v. Cox's Orange Pippin.**—Mr. H. Hendricks (p. 59) protests against the statement of "W. G. C." that the flavour of the above Apple is "only slightly behind Cox's Orange," and considers such verdict unjust. I think that many will be inclined to think that "W. G. C." errs, if anything, on the side of leniency to the Newtown Pippin. Personally, I hold that the flavour of that Apple is a good deal more than slightly behind that of Cox's Orange Pippin. It may be, as your correspondent hints, that the fruit that I and others have tasted were not genuine Newtowns; be that as it may, none of them—and I have sampled many—approached the flavour of Cox's Orange when in perfection.

It is unlikely that the best specimens of Cox's Orange would be exported to New York, as West-end fruiterers are always on the look-out for such, which command a ready sale at prices that are remunerative to the grower and shopkeeper alike. I know for a fact that some exceptional examples weighing 9 ozs. apiece were retailed in 1893 for 8d. each.—S. W. F.

## FERNS.

### CRESTED PTERISES.

MANY of the crested and tasselled varieties of Pteris are still among the most popular for decoration. Although I have frequently heard them referred to as monstrosities by those who prefer the normal forms, it is certain that they are generally admired and very extensively grown, new varieties being eagerly sought after. Of Pterises we have such a number of varied forms, that it would seem almost impossible to find another quite distinct variety. One of the latest additions, and one which will be sure to find general favour, is *Pteris cretica* Wimsetti. In all other crested forms of *cretica* and *serrulata* the basal portion of the pinnae is contracted rather than otherwise, the multifid growths taking the form of a branching crest or a dense terminal tassel. The distinctive character of *P. c. Wimsetti* is that, in addition to the terminal crest, each pinnule is broad towards the base and cut down into irregular segments, these in some instances being again lightly crested. These and the terminal crests being very light, the fronds stand erect. Like all of the *cretica* type, it is of free growth, forming a most elegant plant for decoration, and will be sure to become popular. Of other crested forms of *cretica*, *nobilis* is one of the most distinct. The fronds grow quite erect and are broadly crested. Even from the first tiny fronds of seedlings it is easily identified by the broad crests. There is a variegated form of somewhat similar habit. The ordinary form of *cretica cristata* is also very popular. There are several slight variations of this, that with the broadest pinnae being the most useful. All the crested forms of *cretica* differ from those of *serrulata* in having broad flat crests instead of the finely cut, dense tufted tassels so often seen in *serrulata*. Of recent additions to *P. serrulata*, *gracilis multiceps* is worthy of note. This has very slender drooping fronds, the long narrow pinnae each terminated by a tuft of finely-cut multifid growths. The fronds hang over and completely cover the pots. To grow it successfully, it requires to be elevated either by standing the pots on pedestals or suspending them. *Pteris ser. cristata compacta* and *densa* are both useful varieties, the latter forming very dense terminal tassels. In this as in several other varieties of *serrulata* the abnormal growths will continue to develop in the old fronds. Of the tall growing sorts that known as the Chiswick variety is one of the best. In *P. serrulata gloriosa* we have another distinct form.

There are now several distinct varieties of *P. tremula*, *Smithiana* being the most densely crested; it makes a beautiful plant, but owing to the continual growth of the multifid fronds they are very tender and brittle, which has prevented this pretty Fern from becoming so popular as was anticipated when it was first distributed. *P. tremula elegans* is another pretty variety. Instead of the erect tufted growth of the former this has drooping fronds, the pinnae being much contracted, each terminated by a light crest, the fronds terminating in a broader branching tassel. *Pteris reginae*

*cristata*, of which a good coloured plate is given in Schneider's "Book of Choice Ferns," should be included, it being one of the most distinct of recent additions to crested Pterises.

Almost all the crested Ferns may be raised from spores, and although occasionally a good deal of variation will be found, yet, as a rule, they are reproduced fairly true. As most varieties deteriorate with age, it is advisable to grow others for succession. It is a mistake to suppose that repotting should be confined to any season of the year. Young plants may be potted at any time after the pots are well filled with roots. I do not recommend overpotting, but Ferns—more especially the free-growing Pterises—are often kept in too small pots and starved. Where it is necessary to limit the size of pots, liquid manure or any of the artificial fertilisers may be used frequently, but not too strong. This will materially increase the size of the fronds, and favour the further development of the multifid growths. A good rich loamy compost will be found to suit all the free-growing Pterises better than peat, and plenty of daylight is quite as essential to Ferns as it is to flowering plants. A. H.

### CRESTED FERNS.

THERE are very few distinct crested varieties of the Maiden-hair Fern, considering the number of seedlings raised. The most recent addition is *Adiantum versailleense*; this has rather short, erect-growing fronds, which terminate in a corymbose crest. It makes a very pretty plant, and I find it is easily raised from spores. *A. cuneatum grandiceps* is perhaps the most popular of the crested *Adiantums*; this also comes true from spores, and to grow it successfully the pots should be suspended, as the long drooping fronds are borne down by the tufts of multifid growths, and these can only finish off properly where they have plenty of space and light. I have seen a crested variety of *A. elegans*, but I am not yet able to say if this will prove a useful variety. *A. incisum multifidum* is the only other crested variety of any note. Of *Aspleniums* we have nothing remarkable in crested forms; this is probably owing to most of this genus being propagated from the bulbs produced on the fronds. Among seedlings of *A. nidus* I have seen some with slightly crested fronds, but they grow out as the plants advance. *A. hemionites palmatum* is the most distinctly crested that I am acquainted with in this genus. *A. Drueryi* (a seedling from *A. Baptisti*) is an interesting variety with irregularly broadened and twisted pinnae. Of the hardy species there are numerous varieties, especially among the *Athyrium* group.

Of the *Davallias* we have only two; these are *D. Mariesi cristata* and *D. elegans polydactyla*. If these were more frequently raised from spores instead of dividing the rhizomes, we should probably get more varieties, besides which seedlings make much prettier plants. I have seen several plants of *Lomaria gibba cristata*, but it seems very difficult to propagate. I have never known a batch of seedlings to be raised, although fertile fronds are produced. *Lomaria discolor bipinnatifida* may sometimes be raised true from spores, though a good portion will revert to the normal form. The crested *Doodias* are more prolific, of which *D. aspera multifida* is the prettiest, the red-tinted young fronds being particularly attractive. Of crested gold and silver Ferns there are several distinct varieties. *Gymnogramma chrysophylla grandiceps* and *Parsonsii* are the best of the golden, and *G. Wettenthaliana* the best silver. These are easily raised from spores, but they vary a good deal in form, and in *Wettenthaliana* the colour of the farina or powder varies also, in some being quite silvery white and in others sulphur coloured. The *Gymnogrammas* also vary with age; while in a young state they may be only lightly crested, the second or third year they

may form dense masses of multifid growths. This occurs more when the plants are confined to small pots.

Among the Nephrolepises we have some very pretty varieties, foremost amongst which is *N. davallioides furcans*. When grown in a suspended basket or pot and treated liberally it grows freely. Another of more recent introduction is *N. d. multiceps*; in this the pinnae are narrower and more forked than in *furcans* and the fronds terminate in a branching tassel, which is sometimes very dense. *N. plumosa* must also be included. This has rather narrow fronds, which are borne down by a heavy branching tuft of multifid growth.

*Microlepia hirta cristata* is a most elegant Fern, just sufficiently tasselled to add to the beauty of the graceful normal form. This is often seen as a large specimen, but it is much prettier as a smaller plant. Grown in loamy soil and well exposed to the light the fronds are of a soft pale green. Plants of this require to be broken up before the crowns get too thick. The same also applies to the Nephrolepises; they all make much finer fronds and are altogether more elegant when grown from single crowns, and if done before they get pot-bound they will suffer very little from being disturbed provided it is done carefully. *Woodwardia radicans cristata* is rare, but very pretty. I have seen a few plants which have been raised from spores, but it is very difficult to get.

Others might be added, but those referred to include all the most useful except those belonging to our British Ferns, and these are too numerous to include in this article. H.

## ORCHIDS.

### IONOPSIDS.

THIS is a small genus of epiphytal Orchids found in various parts of South America and the West Indies. They are small-growing plants, seldom exceeding about 6 inches in height and rather difficult to cultivate. As with all these small-growing Orchids, it is principally in the atmospheric treatment that we go wrong. It is easy enough to find a suitable roothold for the plants, and heat and moisture can be regulated almost at will, but there is still something wanting in our artificial climate. There is very little doubt that plants growing in their native habitat derive a good deal of advantage from the proximity of trees and other larger vegetation, though in what way it is difficult to say. Again, the moisture arising from decaying leaves and from the earth itself, the continual change of air and other climatic conditions, all help to maintain the health of the plants, and none of these can be successfully imitated in our Orchid houses. It is obviously impossible then to serve them exactly aright in the atmospheric treatment.

With regard to the roots, they are very easily surfeited by anything in the way of compost, the plants seeming to lack the power of pushing them through even a thin layer of compressible material. The best growths of Ionopsids I have ever seen were on quite bare blocks of teak, these being sunk into pots filled with crocks, the latter being surfaced with Sphagnum. This kept up a certain degree of moisture about the roots always, and I know that for five or six years the plants succeeded well. Even with this treatment a time comes when the blocks decay and the plants have to be transferred to a new piece, and that probably means a check to the plants, from which they seldom recover. But even supposing the blocks lasted longer, I believe the plants would soon lose their vigour; certainly they would not be so good after six or

are in request. This gives them a chance to establish themselves in their new home, be it in a pot or on a block. Once get a block, for instance, covered with roots, and we are in a fair way to keeping the plants healthy for a few years at least. The little growths as they form must have individual attention in the way of fixing, so that the roots can get a hold, they being apt to get loose, making the plants look untidy and rendering healthy growth impossible. Not that every one will want tying or pegging down, but they must be carefully watched and a little attention given where it is seen to be necessary. These seemingly unimportant and small details will make all the difference between successful culture and the reverse. With regard to temperature, Ionopsids like a nice genial heat, and while often recommended as cool house Orchids, I have never been able to make anything of them in a house such as suits the coolest Odontoglots. Still, too much heat is equally disadvantageous, and the happy medium is what must be aimed at. Such an one as suits the Mexican *Laelias*, but with less sun and more atmospheric moisture, will answer best, and they must not be dried at the roots even in winter. They are very apt to be attacked by mealy bug, and this must be kept under by frequent cleaning. Newly-imported plants often have these insects about them, so that they must be well sponged before being taken to the houses at all. A good deal of confusion exists in the nomenclature of these plants, and not many really distinct species are known. Those most generally cultivated are

*I. PANICULATA*, a beautiful small-flowering Brazilian kind with blush-white flowers, with a purple blotch on the lip, and

*I. UTRICULARIOLIDES*, a kind with pink and white flowers from Jamaica. Many of the others are simply varieties of these two species, and an importation of either usually contains a number of differing tints of colour. They are hardly Orchids for beginners, for reasons stated above, but for amateurs who have been successful with other genera they are a very pretty and interesting family. R. C. H.

*Gentiana thibetica* (syn., *G. macrophylla*). Engraved for THE GARDEN from a photograph sent by Miss Willmott, Warley Place, Esser.

seven years as they were the first few seasons after being imported. Here again is another item of mismanagement. The plants, fresh from their natural home and with all the innate vigour about them, push up strong spikes with dozens of flowers on each out of all proportion to the size of the bulbs. These are all allowed to come to perfection, and not only this, but kept on the plants until they fade. The next year the same thing occurs, and before the plants have had time to establish themselves they are literally worn out with flowering. I would not advise the entire suppression of the spikes, but would either limit their number or the amount of flowers on each to what the plants could safely carry, and should remove these after being a few days open, the pretty branching panicles of bloom being very useful for many purposes for which cut flowers

**Cypripedium Hookeræ.**—Although the flowers are somewhat small, this Burmese species is well worth a place on account of its beautifully marked foliage. This is very deep green, with irregular lines and spots of light yellow. It produces a one-flowered scape, the sepals and petals being yellowish with a green centre to the former, the latter marked on the edge and points with purple. The pouch is small and brownish green. This was introduced in 1862, and is easily grown if given plenty of water at the root and a shady position in a warm house.

**Lælio-Cattleya elegans gigantea.**—I have recently seen several fine varieties of this Orchid, but one bearing this name is the largest flower I have come across. It measures 8 inches across, and the petals are of that bright rosy white so attractive in *Cattleyas* and *Lælias*; the sepals similar in ground colour, lightly spotted with lilac red. The lip is deeper in colour and has the front lobe of a rich purple-crimson, shading to white at the throat and several lines of violet. The many varieties of this Orchid thrive well under the usual treatment recommended for *Cattleyas*, and keep up a long succession of their splendid and elegant flowers. The type is a native of Brazil, introduced to Europe by a Belgian Orchid grower in 1847.

**Saccolabium Blumei Russellianum.**—This beautiful form of *S. Blumei* has the habit of the type, but longer racemes, the strongest sometimes branching at the points. The blossoms are very densely set upon these, and are similar in form to those of the type. The upper segments are

spotted with bright rose, the front lobe of the lip being magenta. It is not unusual for strong plants of this variety to throw spikes 18 inches and upwards in length, and when in full beauty these are magnificent subjects for exhibition. This was named after the late Mr. J. Russell, of Falkirk, with whom it first flowered. *Saccolabiums* require a strong moist heat with plenty of sunshine and as much air as can be given consistent with a high temperature. Small plants are best grown in wooden baskets suspended from the roof, giving a compost of clean Sphagnum and charcoal over good drainage. Larger specimens may be arranged on the central stages, but they must be kept in a good light, or but few flowers will be produced. They require abundance of water at the roots as long as they are growing freely, and while at rest, although they need a greatly diminished supply the utmost care is necessary that they do not remain dry for any length of time. The plants may be lightly dewed overhead while growing freely, but care is necessary not to overdo this.—R.

### BRASSIAS.

AMATEURS on the look-out for easily cultivated and free-flowering Orchids could hardly pick a more suitable genus than *Brassias*, for not only are they very beautiful when in flower, but they are not at all fastidious in their requirements, and, moreover, of that quaint and singular form that delights most Orchid lovers. About a score of species are known to botanists, and these inhabit various parts of Brazil, the West Indies, and Mexico. They are all evergreen pseudo-bulbous epiphytes, botanically resembling *Oncidiums*, but easily distinguished from that genus by the elongated segments and the absence of the excrescence on the lip. The best way to grow *Brassias* is in pots, and these may be of fairly large size in comparison with the plants, these being usually very free rooting, and, moreover, disliking much or frequent disturbance. Good peat and moss kept in a proper condition by a liberal admixture of crocks and charcoal will grow them well, and good drainage is essential to their well-being. They are not much troubled with insects, and ordinary care will keep them right in this respect. During the time they are in active growth they will require a great amount of moisture at the roots, when the pots are full of them, they taking it almost daily. Frequent and copious overhead syringings may also be indulged in without fear if the compost and drainage are right. While at rest less is of course required, but they like a greater quantity than most pseudo-bulbous kinds, and should not be in a lower temperature than about 55° if it can be avoided. Under this treatment they grow very rapidly, small plants soon making good specimens, while back breaks taken off and started on their own account in a couple of seasons make nice little plants that will flower well at the proper season. Any plants that get too large may be divided by cutting through the rhizomes, potting up into as many separate pots as are needed and watering carefully until the roots are moving freely. The best time for all these cultural operations is in the early spring, the plants then having all the best of the growing season to recoup their lost energy before the winter season is on them. The blossoms of all of them last a long while on the plants, those of *B. Lanceana* especially keeping until they quite turn colour before they begin to wither. Perhaps the best half-dozen species in existence are

*B. ANTHEROTES*, a strong-growing, free-flowering and very ornamental Orchid introduced from Ecuador in 1879. The blossoms are produced on long stout spikes from the base of the pseudo-bulb, and each bears a good many flowers 6 inches or more across. The sepals and petals are deep

golden-yellow when fully developed, with deep purple blotches at the base, lip also yellow, spotted with chocolate-brown and a reddish crest.

*B. GIREOUDIANA* is another fine bold-growing Orchid, producing in May and June its long racemes of peculiar flowers. The segments are much elongated, yellow spotted with red, the lip narrow and similar in colour. This likes a very strong heat while growing and is a native of Costa Rica.

*B. LANCEANA MACROSTACHYA* is a beautiful form of this species, sometimes met with under the name of *Lawrenceana*, from which it differs materially, the sepals of the latter not being so elongated as in the former, the spots also disposed differently. The sepals and petals are bright golden yellow with large spots of reddish brown about the base, while the lip is wholly yellow, narrow, and frilled on the edges.

*B. MACULATA* is a very old Orchid, having been in cultivation since 1806. It varies a good deal in shape and colour, and is the species upon which the genus was founded by Robert Brown. It produces its flowers freely in early summer, the typical form having sepals and petals shorter than most other kinds, greenish yellow, more or less spotted with brown or purple. The lip is white with purple spots. This old plant is a native of Jamaica.

*B. VERRUCOSA* is a very attractive and beautiful plant, which flowers at various times during the spring and summer. The long racemes bear from twelve to eighteen flowers, these being large with whitish sepals and petals, spotted with very dark brown or black. The lip is pure white in ground colour, with many bright green warty spots. A native of Guatemala; introduced in 1838.

*B. WRAYE* is also a native of Guatemala, and although sometimes classed as a variety of *B. maculata*, is possibly better known as a distinct kind. The flowers vary a good deal in colour, some of the better forms being nearly pure white with a few spots of purple about the base of the petals, sepals and lip. Other forms are greenish with indistinct markings of brown. H. R.

*Læ'ia autumnalis Arnoldiana*.—A pretty form of this useful Orchid has flowered under this name, but whether it is the correct name or not I am not sure. The plants, in a very bad state, were obtained at a sale of Orchids, and this is the only one that has flowered. It has medium-sized flowers with rosy purple sepals and petals and a nicely coloured lip, the front deep crimson with radiating purple lines and pure white side lobes. It is apparently a weak grower, but this may be due to the unhealthy state of the plants.—R.

*Dendrobium Dearei*.—This useful *Dendrobium* was introduced from the Philippine Islands as recently as 1882, and quickly found its way into almost every collection of any size. It is a fairly good grower with erect stems about 2 feet in length, each bearing a few leaves on the upper portion. It is very free-blooming, the blossoms occurring near the top of the bulbs, each being about 2 inches across, pure white excepting the lip, which has a light green throat. The hottest and moistest place in the East India house should be given it while making its growth, but after this is complete it should be kept at rest by withholding heat and moisture. It dislikes a large pot or a lot of material about its small twining roots, but will usually be satisfactory in a very small receptacle with the usual peat and Moss mixture.

*Galeandra Devoniana*.—This is well worth growing on account of its beauty and the length of time the flowers last in good condition. It is an old species in cultivation, having been introduced from the banks of the Rio Negro in 1839. Although said to grow to a height of 6 feet or 8 feet in its native habitat, it probably never reaches more than half that height under cultivation. It produces erect, slender, leafy stems, from the apex of which the flower-scapes proceed. The blossoms are singular in form and have darkish purple sepals and petals, with a light green edge;

these are thrown back and the lip is spreading in front, whitish, with a great many lines and streaks of purple. The plant is epiphytal naturally, but thrives under cultivation with what may be termed a semi-terrestrial compost. Good peat, with a little of the best fibrous loam and plenty of chopped Sphagnum and potsherds, will grow it as well as anything, but the chief difficulty will be found in keeping thrips and red spider in check. These insects seem to find out *Galeandras* before they touch any other Orchids growing in the same house, and unless repeated fumigations and spongings are resorted to, healthy growth is impossible. Besides this, constant fumigation is not good for any Orchids, and unless very carefully done, the remedy may prove as bad as the disease. A constantly moist atmosphere with a sufficiency of ammonia in it is the most likely one to induce healthy growth in this Orchid. The heat of the East India house suits it best while making its growth, and when this is finished it may be removed to a cooler, more airy structure and the water supply at the roots diminished.

*Habenaria Susannæ*.—Amongst several Orchids of more than common interest in flower now at Kew this is perhaps the most noteworthy. The genus *Habenaria* has been brought a good deal into notice during the last few years, and several new and beautiful species have been added to our collections; in some respects this is the most remarkable. The stem is from 1½ feet to 2½ feet high, bearing curious leaves, whose bases clasp the stem, and which are shaped like the spathes of some Aroids. The flowers are borne at the top, and number two or three to each stem. The diameter of each is just over 2 inches, and the whole flower is white, the lip, however, being of a purer shade than the outer segments. The lip is of a very curious structure; it is three-lobed, the middle lobe being a tongue-shaped blade ¼ inches long; the side lobes are much broader and larger, and whilst the inner margin of each is entire, the outer ones are cut into deep, narrow teeth, almost into a fringe; the base of the lip contracts into a long green spur. The large rectangular column has two prominent decurved horns. The species obtained a first-class certificate from the Royal Horticultural Society about a year ago, having been shown by Messrs. Sander and Co. The *Habenarias* are terrestrial Orchids, and should be grown in a compost of loam and peat fibre, Sphagnum, and finely broken potsherds. After the flowers are past the stems gradually decay, and water should be gradually withheld. *H. Susannæ* requires a mild stove temperature. The species appears to be widely spread in the East, being found on the southern slopes of the Himalayas, Malay Archipelago, &c.—B.

### THE ROCK GARDEN.

#### XIII.

THE two last weeks of July have been accompanied by somewhat colder weather, cloudy days, and abundance of rain. In rock gardens everywhere the glorious colours of summer flowers are already beginning to fade away, and bright flowers blooming at this time of the year are a welcome boon to all who like to see their rock gardens gay with colour when mountain flowers generally are past their best.

#### DWARF ROCK PLANTS FLOWERING LATE IN JULY.

*Erpeton reniforme*, the pretty little Australian Violet, is among the choicest things blooming at this season. In cold northern districts it does not always stand the winter, but in the southern counties it does well in most places, and its charming blue and white flowers, each scarcely more than 2 inches high and springing from a carpet of bright green reniform leaves, are very attractive. Peaty soil and a position at least partly shaded seem to suit it best.

Another dwarf rock plant still flowering most profusely at present throughout the southern counties is *Androsace lanuginosa*, described so often in the columns of THE GARDEN that further comment on its beauty is needless. Thymes generally have finished blooming for the season, but the pretty little *Thymus azureus* is still flowering profusely, and its flowers are shown off to greater advantage by the dense carpet of foliage beneath them. For rocky steps and similar positions few plants are more adapted. *Dianthus alpinus* flowered early in June, but it is at present blooming a second time, not only at Exeter, but in several rock gardens near the south coast, and a more handsome rock plant it would be difficult to find. *Dryas lanata*, too, is still showy with its cream-coloured blossoms, though its congeners, *Dryas octopetala* and *Dryas Drummondii*, ceased flowering several weeks ago. It does not seem to spread so rapidly as the last-named varieties, and well deserves a good place in the rock garden. *Sedum monstrosium* is now in full bloom and its cymes of yellow flowers are showy, but the plant is interesting also when not in flower, on account of the peculiar Cockscomb-like appearance of its crowded foliage. When this *Sedum* has been grown for several years in the same place it is apt to lose its compact appearance and become somewhat ragged. It is advisable, therefore, to strike cuttings (which root very freely) and replant with young plants occasionally. *Polygonum vacciniifolium*, which is now opening its pink flowers, arranged in long, compact racemes, is a most useful rock plant, and is never seen to better advantage than when growing downward over a rocky slope or hanging over the entrance to a cave or rocky recess. Unfortunately, it is not evergreen and does not form its young leaves till rather late in spring, but for this very reason it is admirably adapted for being associated with spring-flowering bulbs, which would look bright and gay when the *Polygonum* would be dormant. *Hieracium albidum* flowers later here than its congeners mentioned in previous notes, and its very pale sulphur-yellow flowers are certainly very distinct and attractive just now. *Saxifraga mutata* is now at its best. I find it does well in a damp, partly shaded position. It has large leaves and throws up numerous flower-spikes a foot or more in height. The individual flowers are pale yellow, with darker centre. *Veronica corymbosa*, with its handsome racemes of blue flowers always looks best in masses, and should be in every rock garden.

#### TALL AND MEDIUM-SIZED ROCK PLANTS FLOWERING LATE IN JULY.

Under this section I would like to mention two excellent rock shrubs, viz., *Hedysarum multijugum* and *Notospartium Carmichaelie*. The former has been mentioned in these columns before, but it is now flowering for a second time and looking as gay as ever. The *Notospartium* cannot be too highly recommended, and in Messrs. Veitch's rockwork at Exeter two very fine specimens were in bloom at the end of July. It is remarkable that although last winter not only the bronze Broom (*Genista Andreana*), but also the common native Brooms were killed wholesale everywhere by the severe frost, this pink Broom of New Zealand has not only escaped, but has flowered more profusely than ever, and its delicate pink blossoms were simply delightful. *Notospartium Carmichaelie* is, of course, not a plant to be associated with small alpines, but for bold and at the same time graceful effect as a single specimen among the rocks or in connection with the taller vegetation forming the

background of the rock garden few plants could be more deserving of a prominent place. A very desirable rock plant of medium size, i.e., about 18 inches to 2 feet in height, is *Dracocephalum Ruprechtii*. It forms a very handsome bush, of elegant habit, and continues in flower for several weeks. The leaves are linear or lanceolate and the flowers are of considerable size, most abundantly produced, and of a showy lilac colour. *Anacampteros Borderi* is not so graceful a plant as the former, but is well adapted for bold effects on the top of a large rock. It forms a somewhat rigid bush not unlike *Sedum macrophyllum* in appearance, and bears numerous corymbs of dark purplish red flowers. It flourishes best in a dry, sunny position. *Coronilla varia*, also now blooming, is a graceful plant in spite of its spreading propensities. For quickly fringing large masses of rocks or dry banks it is excellent, especially when it grows downwards and spreads its rosy flowers over the stones, but it must be kept at a good distance from small alpines, which it would quickly smother by its rapid growth.

Of tall perennials suitable for backgrounds I will mention *Veronica verticillata*, which has long racemes of white flowers on erect stems; *Dracocephalum speciosum*, with mauve flowers; *Heliopsis scabra*, *Helenium Bolanderi* and *Helianthus* of sorts, all with yellow flowers; *Monarda fistulosa*, purple; *Aconitum napellus* tricolor, blue and white; and *Chrysanthemum latifolium*, white. To plant a coarse-growing and fast-spreading plant like the last named into the rock garden itself would of course be a very great mistake, as it would quickly smother everything else, but in a background of trees and shrubs not in, but near a rock garden it might with advantage be used for covering the ground on large bare spots where little else would grow, and thus be effective when seen from a distance.

Exeter.

F. W. MEYER.

(To be continued.)

## FRUIT AND VEGETABLE CROPS.

### SOUTHERN.

**The Hoc, Welwyn, Herts.**—Apples a good average crop. Plums good. Pears very good. Cherries extra. Peaches and Nectarines average. Apricots under. Strawberries very good. Small fruits very heavy crops, and the trees have been remarkably free from both green and black fly.

The early Potatoes in this neighbourhood have been very good in quantity and quality, although the outlook at first was anything but promising.—C. E. MARTIN.

**Dropmore.**—Here in the South Bucks district the fruit crops generally are up to the average. Most kinds of Apples are cropping well (and in some instances too well) on orchard trees, and would be better if considerably thinned. We had a heavy crop of Blenheim's last year, and the trees are rather thin this season, but abundant in the neighbourhood. Other kinds cropping heavily are Devonshire Quarrenden, King of the Pippins, Cox's Orange Pippin, Worcester Pearmain, Fearn's Pippin, Dutch Mignonne, Sturmer Pippin, Wellington, and Ribston Pippin. Of bush trees on the Paradise stock Lord Grosvenor always crops heavily and is the best early kitchen Apple. Grenadier is a close companion, and others are Warner's King, Ecklinville Seedling, Lord Derby, Lanc's Prince Albert, Potts' Seedling, Stone's Apple, Cox's Pomona, Cox's Orange Pippin, New Hawthorned and Worcester Pearmain. Notwithstanding the period of extreme drought, Apple

trees here have made good and clean growths, and the fruits seem almost larger than usual for so early in the season. The severe winter had apparently no injurious effect on fruit trees of any kind. Pears are a very thin crop this year; of many varieties, Williams' Bon Chrétien and Marie Louise are the only ones bearing a fair crop. Orchard Cherries have been a rather under-average crop. Of several kinds, Bigarreau carried the heaviest crops, and wall trees of all kinds were very good and cropped heavily. The last remark also applies to Peaches and Nectarines, which look remarkably well and have made nice growth and kept remarkably free from insect pests. I gathered ripe fruits of Waterloo on July 6. Bush fruits have been plentiful and good. Strawberries good, season rather shorter than usual owing to the dry weather. Nuts of all kinds abundant. There is a fair average crop of Plums this year.—C. HERRIN.

**Grenehurst Gardens, Dorking.**—Strawberries were a most prolific crop. I only grow two sorts, viz., Sir Joseph Paxton for main crop, and Eleanor for late work. I find no other sort to equal them for all purposes on this heavy soil. In the spring of the year I heavily mulch them with half rotten manure, and the latter part of April I give them a dressing of salt, taking great care that the salt does not touch the foliage. This season and 1893 have been the driest that I ever remember, and yet they have been the two best Strawberry seasons with me. Raspberries suffered very much during the last severe winter, and I lost more than half my canes, but the dry summer has suited them and they are promising some very nice canes for next season. The canes which were left are carrying a good crop. Morelle Cherries have cropped splendidly, the fruit large and of good colour. All bush fruits are an excellent crop. Apples also are an excellent crop. Pears are a very poor crop. Quinces are promising favourably. Plums are only half a crop. Peaches were never better. All the Peaches are grown out of doors on a south wall 85 yards long and 14 feet high, and the trees, with few exceptions, are all loaded with fruit. Apricots do not do well with me, and I have now ceased to grow them.

All vegetables have suffered very much this summer owing to the continued dry weather, but since the rain a fortnight ago everything is growing at a rapid rate. Potatoes with me have suffered owing to the long spell of dry weather, and the early sorts are a very poor crop. I hope the late ones will turn out better, the rain, I think, having come just in time to save them.—W. SHEPHERD.

**Brambletye, Sussex.**—The fruit crops in this neighbourhood are very good, notwithstanding the long spell of hot dry weather we have passed through. Apples promise to be a heavy crop and of good quality. The following varieties are bearing heavily and are seemingly suitable for planting in this district: Alfriston, Bismarck, Bramley's Seedling, Wiltshire Defiance, Hawthornden, Hanwell Souring, Lord Grosvenor, Lord Suffield, D. T. Fish, Cox's Orange Pippin, Blenheim Orange, Dumelow's Seedling, Flower of Kent, Worcester Pearmain, Oslin, Keswick Codlin, Lane's Prince Albert, Warner's King and many others. Pears on most trees are rather a thin crop. Standard Plums in orchard are bearing heavily, especially such varieties as Rivers' Early Prolific, Dymond and Victoria. Upon the wall trees the best are Coe's Golden Drop, Golden Esperen, Early Transparent Gage, Bryanston Gage, Kirke's and Jefferson. Damsons are an average crop. Peaches and Nectarines are plentiful, and have had to be heavily thinned. Dessert Cherries have been abundant and the trees wonderfully free from black fly. Morellos are a plentiful crop, but the fruits are rather smaller than they usually are here. Black, Red and White Currants were an exceptionally heavy crop. I think I have never seen a heavier crop of Gooseberries, and all the sorts were equally good. Glad to say the bushes have been quite free from caterpillar. Raspberries were plentiful, but small, and had a very short season owing to the hot weather. Strawberries

were an extra heavy crop, but I had to keep the beds well watered.

The vegetable crops suffered very much through the long-continued drought, but everything has improved wonderfully during the last fortnight. The early Potatoes were very fine; the later crops are looking well and I have seen no signs of disease as yet.—GEORGE F. GLEN.

**Knebworth, Stevenage, Herts.**—The prospects of the fruit crops in this neighbourhood are on the whole extremely good. Apples and Pears are fully up to, if not slightly above, the average in many places. Now that the rains have fallen copiously after the long drought, and if genial weather follows, both the size and quality of the fruit will be much enhanced. Of stone fruits, Peaches and Apricots are above the average, and in size and quality likely to be good; Plums and Cherries barely up to the average. Bush fruits of all kinds are above the average and of excellent quality, though on the lighter and drier soils the fruit is small in size, from the want of moisture at the roots. Strawberries were heavy crops and of excellent quality, but the long-continued drought shortened the season of gathering. The severe frosts of February did little damage, on the whole, to fruit trees. Peaches and Apricots had the unripened tips of the shoots badly nipped, and a few immature shoots here and there in the body of the trees killed, but, as the abundant crops of fruit show, the general fruitfulness of the trees has been affected but little by the long-continued severity of the zero frosts. It is more among the ornamental evergreen trees and shrubs that the severity of the frost has told its tale.

The long-continued drought, now happily broken, has affected much the early and mid-season crops of vegetables. Through that cause both bulk and quality have been much diminished. Indeed, I have no recollection of a season when it has been more difficult to keep up the several supplies of the different vegetables needed in private establishments. Now that the long drought has come to an end, the later crops of Peas and Beans of various kinds, Cauliflowers, Cabbages, and the Brassicas generally, Carrots and Turnips, and late Potatoes are likely to be abundant and good. The heavy showers of rain we are experiencing have, unfortunately, started the late crop of Potatoes in the fields into a second growth, which must to a certain degree affect their quality.—J. KIPLING.

#### MR. A. F. BARRON.

YOUR article in THE GARDEN of last week on Mr. Barron, I hope, will draw out a full statement of the reasons why the council is parting with him. It will be a national loss if Mr. Barron is actually driven from the post of gardener-in-chief of the Royal Horticultural Society's Experimental Grounds, Chiswick.

There is much dissatisfaction all over the country at the prospect of losing Mr. Barron's valuable services, and, further, there is a talk amongst some of the Fellows of withdrawing their subscriptions. The question people are asking is, why do the council want to get rid of a gentleman in whom the horticultural world has such unbounded confidence, and who has at least ten good honest years' work in him, backed by the experience of thirty years' entire responsibility of the society's gardens, wherein he has rendered such signal services in the able and uncompromising manner in which he has conducted the experimental trials at Chiswick, gaining for the R.H.S. a world-wide reputation. Your remark is well timed that Mr. Barron, "of all connected with the society, has best deserved the confidence of all interested in the society and its work," and so apparently thought the council a year ago, judging from the following, which appeared in the council's report in the R.H.S. Journal of August, 1894, that "the society's general work of scientific experiment and investigation, and of the practical trial of various plants, has been going on steadily

at Chiswick under the superintendence of Mr. Barron. Trials have been made of 48 varieties of Onions, 63 of Peas, 104 of Strawberries, 68 of new Potatoes, 50 of Tomatoes, 23 of Celery, 20 of Runner Beans and 24 of Endive. In the floral department 400 varieties of Carnations, 70 Pinks, 500 Pæonies, as well as many varieties of Phloxes, Cannas, Sweet Peas, Violas and Irises have been tried. Reports founded on the work of these committees will be found in the society's journal, vol. xvi., parts 2 and 3, now issued." Those of us who have done clearing-up work of this sort on our own account can appreciate the herculean labours of the gardener-in-chief in bringing important trials (as above recorded) to a successful issue. The work on Carnations, Pæonies and Phloxes alone would have driven an ordinary man mad. Work of this sort needs a peculiarly constituted mind rarely to be met with, besides immense experience. The council cannot be in their right minds to act as they are doing; they cannot replace such a man. If they were wise in their generation they would associate with Mr. Barron a good man, who in the course of the ten years named might be able to take up his work, but they might have to change such a man many times before they hit on the one with the capacity, patience and dogged perseverance needed for such a post. Then again, the man who is responsible for these trials and who prepares the reports is the gardener-in-chief, and as such has hitherto signed all such reports; but a new departure of a significant character takes place in reports just referred to. Mr. Barron's name does not appear, contrary to what has been the custom hitherto. Is the council aware that this omission is a serious drawback to the value of the reports in vol. xvi.? Mr. Barron's name attached to reports has been our guarantee for the genuineness of the trials made at Chiswick. We knew, associated with his name, they were free from favouritism and done with extraordinary care and accuracy, an accuracy almost unknown in Chiswick Gardens before General Scott installed Mr. Barron as gardener-in-chief. The committees are important factors by giving authority to trials, but what is the value of the work of three or four hours compared with that of the gardener-in-chief, who has spent days, and perhaps weeks, with book in hand, and has matured experience of the subject, and feels his responsibility in assisting the committees? Mr. W. Marshall, chairman of the floral committee, and member of the Chiswick Garden committee, I am sure, is the last man to claim more for his committees when at Chiswick than confirming previously prepared work, not that Mr. Barron ever pushes his conclusions on a committee, but all the same he has done the work for the committee and prepared the reports. The departure in omitting Mr. Barron's name looks as if 117, Victoria Street wished an undue credit for the work on these reports, by omitting the honoured name of Mr. Barron. The Victoria Street department's share of the work must have been merely clerical. Should the services of Mr. Barron not be retained at Chiswick, the gardener-in-chief, whoever he is, must have a free hand, get credit for his work, and feel his responsibility and sign all his reports, otherwise the Fellows had better look upon him as a mere cipher, retained for the glorification of someone else. The council will do well to look to this, or the Fellows may exercise their rights at the general meetings. I think the society is drifting into bad ways, which I fear will be worse than any of the many bad ways it has fallen into during the last fifty years. Each time it has fallen into bad repute it has been found more difficult than before to get it on its legs again. The council cannot at present, or indeed at any time, afford to bring itself into conflict with public opinion.

The present council reminds me of the Pharaoh of old who knew not Joseph. I will, therefore, remind them of the time when the name of the R.H.S. stunk in the nostrils of horticulturists and was a by-word amongst men. Flower shows would at that period have been impossible but for the personal influence of Mr. Barron. Old

exhibitors whom he induced to exhibit were wont to say: "Yes; we do so out of respect to you." For this alone Mr. Barron should have our gratitude and be treated as the best friend the society has had since the death of the Prince Consort.

Many are the reports afloat as to the reasons of the council in parting with Mr. Barron. I will deal with three. The first: The council feel, it is said, that more scientific work should be done at Chiswick. And why not? The fault is their own; it is simply a question of engaging scientific men. Formerly we had a scientific director; then a botanical director. Why not reinstate these offices, or one of them, and get a young man from the laboratory of Sir J. B. Lawes and Sir J. H. Gilbert as scientific director. Hire a field and let him carry out experiments as to the value of different manures suitable for gardens, and set a house apart at Chiswick to experiment with manures for plants in pots. Anyone who remembers the experiments of Sir J. H. Gilbert with Grasses at the gardens of the R.H.S. can testify that Mr. Barron gave the utmost attention to the experiments and rendered valuable assistance. If this meets the eye of Sir J. B. Lawes or Sir J. H. Gilbert, they may give a testimonial worth reading on the subject of this letter. The second report is that certain members of council have an itching to become amateur co-operative nurserymen, and why not? There is plenty of land to be had cheap enough, but I hope the council will not play with the Fellows' money and dishonour Chiswick Gardens by growing plants for sale at 2d. per pot. We do not want Chiswick to bring in a revenue, that comes from the subscriptions, and all we ask as Fellows is that the council spend our money carefully and wisely. The latest financial report of the disbursement of moneys I have of the society is August, 1894. I find that 117, Victoria Street and Drill Hall managed to spend £1875 5s. 5d. This is too much for our income. Chiswick spends £1624 15s. 1d., while the produce of the garden realised £404 9s. 2d. Considering the acreage and the important work done at Chiswick the allowance is simply starvation. Some of the money should be taken from Victoria Street and given to Chiswick, which is the spending and working department. But for Mr. Barron working along with his unpaid students the trials could not be made with the labour allowed. The third report is that the Chiswick Gardens are not well kept. This is a false impeachment and can easily be disproved. I have made myself acquainted on this point, and can testify, considering the poverty of labour Mr. Barron has at his command, the gardens are wonderfully well kept out of doors, and indoors, considering the nature of the glass, things could not well be better. Fellows should visit the gardens and judge for themselves. If, perchance, they find some rusty plants in one of the houses, the gardener-in-chief will give a satisfactory reason for their condition. The garden committee should have ordered them to be burnt long ago.

There is a pamphlet in circulation by the R.H.S., without date, entitled "A Short Historical Sketch of the R.H.S.," in which the writer says that £30,000 had been expended on the "Transactions" of the R.H.S. in old times, and adds "they are full of practical information of the highest value, and from which writers on gardening subjects have derived, and even still indirectly derive, a large part of their knowledge." A sad commentary on this is the action of the council regarding the society's journal of the present day. Up to the end of 1891 the journal of the R.H.S., like the journal of the Royal Agricultural Society, was free to all who thought well to reproduce the information contained in it. In 1892 a new departure took place, and it was entered at Stationers' Hall, and is now a sealed book to the gardening press, to be reserved for the use of future generations. Surely the R.H.S. does not live for itself alone, but for the good it can do in its day and generation. Why not therefore let any knowledge that comes to its mill be as free to all as the winds of heaven? I call upon

the Fellows of the R.H.S., if they desire to save its reputation and its most able man, to require that the council call a special meeting of Fellows to discuss the position of affairs. It does not appear to me that it was the interests of the society which led up to the high-handed action of the council to make such a departure from the honourable presidents of all past councils of the R.H.S., but to serve some private interests, requiring the removal of the best servant the society has ever had, a man who has never been the tool to anyone, and further, it should be stated that years ago Mr. Barron refused a position far more remunerative than that of the R.H.S., but he refused because he loved the work of the Chiswick Gardens. In these gardens under Mr. Barron much eminent work has been done in the past, and can be done by him again with the means of doing it. During the days of the South Kensington Gardens as many as 100,000 pot plants were produced annually under Mr. Barron's directions, so that if the council desire to be nurserymen or market growers they have the man who can do the job for them and pay a dividend to the Fellows if we choose to descend from our high estate to become grovellers. Hybridisation was successfully carried out under Mr. Barron's directions. Take the Coleus for example, a despised plant just now, but when it was first seen it was looked upon as a modern wonder and brought a heap of money to the coffers of the society. The same man could do equally good work if he had the means and opportunity of doing it. Let the society ask Col. Trevor Clarke's opinion of the value of Mr. Barron's services, and his opinion is worth a great deal; he saw more of the work done at Chiswick than almost any other man at the time.—PETER BARR.

—The reference made in THE GARDEN to the retirement of Mr. Barron from the Chiswick Gardens, recently announced as being forced by the report of an outside committee selected for the purpose by the council of the Royal Horticultural Society, comes with exceeding surprise to the great body of the Fellows, with whom Mr. Barron has so long been a most acceptable and esteemed personage. It would seem as if the actual cause of this proposed retirement was but just leaking out, and, evidently anticipating severe criticism for what seems to be a very underhanded proceeding, so much publicity has now been given to the promised pension to Mr. Barron as though it might be useful in deprecating that criticism. Presumably the council of the Royal Horticultural Society consists of a body of gentlemen none of whom could be capable of doing personally anything improper, and it is difficult to understand that anything could be done collectively that is unfair or underhanded. Still, the fullest explanation as to the reasons that led to the appointment of this committee of inspection must be made absolutely clear. We are entitled to ask also that not only shall the names of these persons be published, but also that the report signed by them, whether unanimously or otherwise, shall be published also. This is a matter which concerns all the Fellows as much as it concerns the council. Mr. Barron was the servant of the society years before a single member of the present council held office. He always in the past enjoyed the fullest confidence of previous councils just as now he enjoys the fullest confidence of the entire body of Fellows. Most certainly, too, he has knowledge rendering him specially fitted for the position he fills and that places his head and shoulders above all others, whether friends or antagonists. We as Fellows cannot wait six months for a complete elucidation of all the mystery which surrounded this retirement of the society's most valued servant. Fellows should go to Chiswick and there see what the conditions found in the gardens are. A Fellow who saw them with me for the first time recently was charmed. He said that he had seen nothing in gardening so good, so diversified, and so interesting to him anywhere. That would, I am sure, be the testimony of many Fellows and visitors if they would take the trouble to go to Chiswick and see for themselves what is being done there.

Where is the man who thinks, especially with Mr. Barron's comparatively poor aid, that he can do better? I dare to say it will be a cowardly act to refuse to publish this committee of inquiry's report, because that alone can justify an act that is at once creating so much criticism and arousing such deep antagonism. I do not know why alone of the gardening papers you should publish the statement that this retirement is due to a certain committee's report. The fact can hardly have been a secret from other papers, though it was to the mass of the Fellows. For such publication THE GARDEN merits the warmest thanks of a deeply concerned F.R.H.S.

#### NOTES FROM CHISWICK.

Those interested in the best of garden flowers, fruits, and vegetables might well visit the gardens of the Royal Horticultural Society at Chiswick. Trial collections of Fuchsias, Cannas, Violas, Asters, Sunflowers, and perennial Phloxes are very interesting to those who grow these flowers. In the large vinery devoted to Muscats there is a collection of the best varieties of Tomatoes in pots, and there is also a good collection of Figs in pots, a special culture for which Chiswick has long been famous, as it was formerly for its varieties of the Grape Vine. Trials of runner Beans, Cabbage, and Lettuce have been and still are being conducted, and the cordon Pears on the lower wall are a most interesting study, many of the best and most useful varieties, such as Marie Louise, Louise Bonne of Jersey, Souvenir du Congrès, &c., being heavily laden with fine fruits. Not the least interesting portion of the garden is the velvety grass plot stretching from the old council room to the great vinery. A circle of poles and chains most simply and gracefully covered with the wild *Vitis riparia* of the United States gives us a glimpse of the freshness and beauty possible of attainment by the more general use of the most distinct and beautiful of N. American and Japanese Vines. Now that the Bamboo is being grown as the epitome or expression, as it were, of beautiful grassy-leaved vegetation, we might do worse than use the wild Vines of the temperate world as typical of beauty of a totally different, but not less important, character. Ivies and Grape Vines would add a good deal of beauty to bare walls, pillars, gables, and tree trunks nearly everywhere if tastefully employed, and there is now at Chiswick a named collection of all the best Ivies well worth careful study.

Having known the Chiswick Garden many years, and having seen it before its area and importance were restricted, it was with mingled feelings that I visited it the other day. Formerly it consisted of about 33 acres with a fine arboretum, a hardy fruit orchard, a fertile Peach wall, an American garden and wilderness. It is now a plot of 12 acres or 13 acres only, but still potent for good as of old. Repairs are badly needed to a couple of the older houses and to some frames, but a still more important matter requiring attention is the necessity that has long been felt for a better staff of working gardeners. As the Chiswick Garden, under the auspices of the R.H.S., is really the only public and independent trial ground in England, it is to be hoped it will be increased in its efficiency and importance, and not be allowed to degenerate into a second-rate market garden. When the means and objects aimed at are duly taken into account, the present condition of the Chiswick Garden is most creditable to its genial and loyal superintendent, who is being obliged to leave it after a loyal service of nearly forty years, respected by all true horticulturists in this country and elsewhere. F. W. B.

**The weather in West Herts.**—Most of the days of the past week were below the average, but, on the other hand, all the nights except one were warm. The temperature of the soil at both 2 feet and 1 foot deep now stands at 62°, or exactly the same as at the beginning of the week. The reading at 1 foot deep is 1° below the mean for

August. During the present month there has been as yet only one day without some rain, the total fall amounting to 2½ inches, or very nearly the average for the whole of the month. The wettest day of all was the 13th, when nearly 1 inch was deposited. Since the beginning of the month more than 1½ inches of rain-water has already passed through the heavy, and about 1¼ inches through the light soil percolation gauge. The winds have again come from some southerly or westerly point of the compass.—E. M., *Berkhamsted*, Aug. 15.

—A warm week, the temperature in shade on each day rising above 70°, and on the hottest day to 79°. Several of the nights, however, were cool for the time of year. The temperature of the ground at 2 feet deep has now risen to 65°, and at 1 foot deep to 67°, the latter reading being 4° above the average for August. No rain has fallen during the week, but owing to the previous heavy rainfall a little rain water still continues to come through the percolation gauges. The air has remained very dry during the daytime, and on the 19th the difference between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounted to 14° at 3 p.m. The winds, which have been light, have again come almost exclusively from some southerly or westerly point of the compass.—E. M., *Berkhamsted*.

**Gentiana edscendens.**—Having tried in vain to get some plants of this, I shall be glad if any reader will tell me where it can be had.—B.

**Botany of Central America.**—Would you kindly inform me through your columns where I could obtain a book on tropical botany that would give me some idea of the botany of Central America?—A. W. COFF.

**From Norfolk Island.**—May I venture to trouble you with one or two questions, which, if you would answer through the medium of THE GARDEN—for that paper finds its way to this remote spot—I shall be greatly obliged. 1. How can I destroy Dandelions, they are so thick on my lawn that scarcely any grass is visible? They grow and blossom all the year round, and spread rapidly in the adjacent paddocks. 2. May a weed-killer, for example the Acme, be used in the neighbourhood of wells? How near may one use it to a growing hedge, and if on a path will it destroy adjacent grass, &c.? May it be used to destroy patches of weeds in a grazing paddock while horses are still in?—P. HERBERT METCALFE.

**The plague of birds.**—Would any of your correspondents learned in the law kindly state the provisions of recent legislation with regard to small birds? What information I have been able to glean has been but scanty, though so far as it goes it seems to show that county councils possess absolute power to schedule under the Wild Birds Protection Act every bird that flies if they be so minded. My gardener declares that he is liable to heavy penalties if caught taking nests, the only practical means of keeping down these feathered pests, shooting being out of the question in a well-kept garden. In this district we are over-run by birds of every size and description, and the damage done by them is quite incalculable. If we are to be hampered in this fashion land must sooner or later go out of cultivation, for gardening under such heartbreaking difficulties simply means ruin.—AN OXFORDSHIRE AMATEUR.

**Water Lilies in hard water.**—Certainly the non success of Mr. Milne-Redhead is only due to an excess of lime in the water. If he will examine the underside of one of the older leaves, he will find a complete incrustation of lime.—MAX LEICHTLIN, *Baden-Baden*.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, August 27, in the Drill Hall, James Street, Victoria Street, Westminster, at 3 o'clock. A paper by Mr. C. F. Pause on "Crotens and Dracenas" will be read.

No. 1241. SATURDAY, August 31, 1895. Vol. XLVIII

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## FLOWER GARDEN.

### HARDINESS OF CARNATIONS.

In face of the fact that Carnations suffered severely from the past winter, it seems idle to debate the question of a trace of delicacy being present in the constitution of the plants. Before, however, we can be certain of that being the case, it may be well to examine closely the treatment generally accorded to Carnations, and perhaps it may appear that the hardiness of the plants on the one hand, or their assumed delicacy on the other, will be found to be altogether a matter of treatment. No doubt the complaint has been general of Carnations having succumbed to the severity of the winter. Less, however, has been heard of those that failed to survive the drought of summer, though very many gave way then, with the apparent result that Carnations are incapable of resisting either extreme heat or intense cold, and thus in a degree stamping a hardy plant with the possession of qualities that detract very much from its usefulness.

That there is no inherent weakness or lack of hardiness in the plants is proved by the behaviour of seedlings. These have everywhere passed the ordeal of heat and cold without receiving the slightest damage. I have here, for instance, a long border of seedlings of all colours, white, yellow, and apricot to maroon, with flakes and bizarres, Picotees of white and yellow grounds, and while all are in splendid health, it seems strange that plants propagated from these perfectly hardy subjects should in the process undergo some mysterious change and be unable to withstand a like degree of cold. It is a condition we do not find occurring in the case of other hardy plants, nor ought it to happen here. Turning to beds occupied with named, and therefore propagated plants, we have examples of younger subjects which have not had the same time to become established in the ground, and therefore less able to stand the vicissitudes of weather, and it is, I believe, just this question of time to become established that makes the difference between a Carnation being hardy or tender. None of the plants put out here last autumn gave way with the exception of those that were unhealthy. None of these, again, suffered from the drought, while those that were put out in spring did so, some of them even to the extent of dying. In practice I find that Carnations with good roots, planted in the beginning of September, invariably do well, while if left till the end of that month there is a certain amount of risk of failure. In the same way, unless special attention is given to the plants, spring planting always yields less good results than autumn planting. There is, of course, always a chance of disease affecting plants. That arising from climatic effects is beyond our control, but one of the most dangerous is largely due to injudicious treatment. I refer to the mischief effected by *Tylenchus*, the Carnation eelworm. Of all the troubles to be contended with this is by far the worst when it attacks the plants. Unfortunately, many gardeners are incapable of diagnosing its symptoms, and plants are consequently allowed to become a prey to this insidious enemy without anything whatever being done to effect its dislodgment.

It hardly ever appears unless the plants are grown with much manure. By careful treatment I have been fortunate in cleaning diseased stock, and so fearful am I of by any means allowing it to gain a footing that I hardly ever employ organic manures. If the ground is in good condition, surfacings of chemical foods are generally sufficient to enable the plants to bloom to perfection.

With regard to whether some varieties are less hardy than others I imagine there is in this respect no difference; but some varieties are no doubt less robust than others, and some are more susceptible to disease. In any case there is, I think, no question that those possessed of little vigour ought to be allowed a treatment diverse from that given to more robust sorts. I make up a thin surfacing of sandy open soil for varieties that I know to be somewhat "miffy," and this has the effect of inducing a healthy growth. By degrees these will give place to others of equal beauty, but possessed of a stronger habit of growth. Meanwhile, a little attention to soil will, I am sure, do much to keep even the least robust kinds in good health.

*Tynningham.*

R. P. BROTHERSTON.

**Tufted Pansy Charm.**—This soft lilac self-coloured flower received a special commendation at the congress held at Birmingham last year, but in the matter of a good bushy habit it is deficient. A long straggling growth should be enough to condemn a tufted Pansy, be the blossom ever so fine. Not a few sorts, however, which seem indispensable for exhibition may be mentioned in this category, and I fear that were the desirable tufted habit insisted upon, such beautiful varieties as Archie Grant, Countess of Kintore and Mrs. H. Bellamy would be but little grown.—H.

**Lilium Leichtlini.**—This is one of the most graceful of all Lilies and quite distinct. The stem is slender and the flowers, which are supported by delicate pedicels, have the segments reflexed after the manner of the Tiger Lily. The blossoms of Leichtlin's Lily remain in perfection much longer than those of the majority of Lilies. It is by no means a robust species, and a good thriving specimen is an exception. A well-drained sandy loam seems to suit it best. This pretty Lily is a native of Japan, and bulbs of it are sent to this country during the winter months, but all those that are sold as *L. Leichtlini* cannot be depended upon to be true, for whether I have been more unfortunate than others I cannot say, but from the proceeds of different sales I have obtained quite as many bulbs of *L. Batemanni* and *L. pseudo-tigrinum* or *L. Maximowiczii* or *L. jucundum*, as it is at times called, as I have of the true *L. Leichtlini*. The bulbs of these three are so much alike that it is quite impossible to select them from each other with certainty.—H. P.

**Phlox Drummondii as an exhibition flower.**—At the exhibition of the Taunton Horticultural Society on the 8th inst. cut blooms of *Phlox Drummondii* were numerous and very finely shown in bunches. The schedule of prizes did not specify the number of trusses which should form a bunch, but five or six appeared to be the number employed, and as some of the foliage of the plants was used as a setting for the bunches, the effect was very pleasing. The varieties of the improved form known as *grandiflora* were employed, and the flowers being cut when fresh and green the bunches were very effective, and they appear to have quite driven the *Verbenas* from the field. To have fine blooms the plants should be grown in good soil. Each individual should have ample room in which to develop; hence it is well to peg down in position the leading shoots. A little judicious thinning may be done with advantage, and if some protection could be afforded from showers a short time previous to the blooms being cut, the colours will be all the more vivid.

No *Verbena* ever raised can compare with a truss of *P. D. splendens grandiflora* for exhibition. There is a good range of self colours among the varieties, and there are some showy ones having dark centres, broadly bordered with a paler colour. The striped flowers lack distinctness of character, the white grounds are too much blotted out with heavy flakes of colour, and there is need for improvement in these varieties.—R. D.

**Tufted Pansies—their sportive habits.**—These popular plants have a tendency to change the colours of the flowers, so that in some cases three distinct sorts appear on the same root or tuft. By propagating from the branches, which produce the variations, many new varieties have thus been obtained. Perhaps the most notable instance of this habit is the lemon-yellow *Ardwell Gem*. It sported into *White Duchess*, a pure white, distinctly edged blue, then *Goldfinch*, yellow, edged pale purple, is produced, and this in turn gives a sport with richer shades named *Duchess of Fife*. It again gives a slate-blue, introduced as *Annie Wood*. The changed colours are mostly constant, but occasionally we find them revert to the original. I noticed, for instance, blooms of *Ardwell Gem* on a plant of *White Duchess*. The type of flower in all the above-named sorts is a splendid one. The tufted habit is perfect. They have passed the severe test of hot, dry weather the best of all, and the plants are now, as they have been since early spring, literally full of bloom. *Ardwell Gem* and its sports have also the great merit of being proof against mildew, and are therefore of especial value for growing in the south.—S.

### HARDY FLOWERS FOR CUTTING.

Now that a constant supply of cut flowers is required for indoor decoration, which supply ought to be maintained without diminishing the attractiveness of the flower garden, it is well to cultivate in the kitchen garden or in spare ground a reserve of such perennials, biennials and annuals as will be useful for cutting. Tall flower-spikes being almost a necessity for the long slender vases so much in vogue at the present time, plants producing these should for the most part be grown. Passing over the *Narcissi*, which are indispensable during the spring months, we have first and foremost the *Gladiolus* family, commencing with the early varieties, of which *G. Colvillei albus* *The Bride*, *Fire King* and *insignis*, scarlet and crimson; *Blushing Bride*, white with carmine flakes, and *Duke of Albany*, crimson with white flakes, are amongst the best. Later on come *Lemoine's* beautiful hybrids and the dazzling scarlet *G. brenchleyensis*. Leaves of *Kniphofia* associate well with the early section, and those of the *Water Flag* with the later. The *Montbretias*, of which *crocosmiaeflora* is one of the best, should be grown in quantity, the blooms, orange-scarlet shading to yellow, being of a striking colour and the graceful scapes well adapted to effective arrangement. In light soils the *Montbretias* increase very fast, and I have seen a plot, which was planted thinly, filled with an almost solid mass of bulbs in three years' time. Hybrid *Alstromerias*, with their beautiful gradations of tint, ranging from cream colour to crimson, should have ample space allotted to them. The *Irises* are invaluable for decoration, although, the sections requiring different treatment, it will be found difficult to succeed with all alike if grown in similar soil and situation. *I. stylosa*, which produces its beautiful and sweetly-scented flowers during the winter, does best on sloping ground in light soil, preferring a position sheltered on the north and east. The *Spanish Iris* (*I. Niphion*), of which only the self-coloured varieties should be grown, likes light and sandy soil. *Golden King*, orange; *Canary-bird*, yellow; *Snow Queen*, white; and *Celestial*, blue, are good varieties. The *English Iris* (*I. xiphoides*) flourishes in a heavier soil. In this section as well care should be taken that the whole-coloured whites, blues and mauves are obtained, and that the splashed varieties are excluded from the collection, as these latter have little value from a decorative

point of view. The self colours are variously named by different nurserymen and are very equal in merit. The German Flag (*I. germanica*) manages to thrive in almost any situation, and I have seen it equally at home on hard baked railway embankments of poor soil and in shady beds of deep rich loam. There are many beautiful varieties—*Pallida*, pale mauve, and *pallida dalmatica*, mauve-purple; *fiorentina*, white with a suspicion of lavender, the three foregoing being sweetly perfumed; *flavescens*, sulphur-yellow; *atro-purpurea*, very dark purple; and *Princess of Wales*, a grand white, are about the best of the self coloured. The Japanese Iris (*I. Kämpferi*) should be grown in light rich soil and should be afforded abundant moisture during the growing season. The older importations possessed drooping falls, but in the newer kinds these spread out horizontally, some of the flowers measuring over 6 inches in diameter. There are double and single forms and the colours range from pure white to dark purple and lake. Three splendid Irises are *ochroleuca*, *aurea* and *Monnieri*, the colours being respectively white with yellow flake, golden and yellow. When well cultivated these exceed 5 feet in height and produce spikes of several blossoms. The variegated Water Flag is extremely handsome in leafage during the early summer before its flowers, which are identical with those of the common Flag of the English water meadows, are produced, after which the variegation departs. The sword-shaped leaves are valuable for decoration when at their brightest, and I have known the plant mistaken for the variegated New Zealand Flax when well grown.

#### WHITE LILIES,

when they can be spared, are always acceptable, the Madonna Lily (*Lilium candidum*) being the especial favourite. This, when healthy bulbs are procured, will flourish in any soil and situation, but there being now a disease prevalent that often decimates whole ranks of these beautiful plants, no certainty of success can be depended upon. Personally, I should be inclined to purchase only such bulbs as I knew had flowered satisfactorily for some seasons. There might be some difficulty attached to such a course, but the disappointment of a total collapse just as the plants are giving promise of profuse blossoming is so great that any certainty of avoiding such disaster would more than repay the trouble. It is notable that in many cottage gardens these Lilies have been growing for years without showing a sign of disease. *L. longiflorum* *Harrisi* is another highly decorative Lily, its long, white trumpets being peculiarly adapted for arrangement in vases. With me, some bulbs that were brought from Bermuda were planted in ordinary garden soil, and have since bloomed satisfactorily every year. *L. excelsum*—sometimes known as *L. isabellinum* on account of the tint of its flowers—is also handsome in a cut state, as are *L. croceum* and the Tiger Lilies. Perhaps the most graceful of all the Lilies is *L. canadense*; this should be grown in peat and in a partially shaded situation. I know of no other Lily that has so light and elegant an appearance when arranged effectively, the poise of its deeply-spotted, starry bells, suspended from the long and slender foot-stalks, being especially beautiful. The *Belladonna* Lily may here be mentioned. If grown in a narrow border at the foot of a hot-house wall, a goodly show of flower spikes, which are in great request for the house, will be produced year by year in the autumn. *Solomon's Seal*, though not striking in colour, is most attractive in form, and if well grown in a shady spot, will throw up long, curved shoots studded with pendent blooms, which in the late spring are most useful.

Of the perennial Campanulas there are many that are excellent for cutting. *C. grandis alba* is particularly effective, its tall spikes of bloom (from 2 feet to 3 feet high) being studded with open satiny-white bells, that stand out at right angles to the stem. The Peach-leaved Campanulas (*C. persicifolia alba* and *C. p. a. flore-pleno*) are both invaluable, and last longer in a cut state than

*C. grandis*. *C. pyramidalis alba*, which should be grown as a biennial, is also fine, and should be cut immediately after the first blooms are fully expanded. If the individual flowers are removed as soon as they fade, the flower-spike retains its beauty for a considerable time. *Erigeron speciosus*, a very profuse-blooming plant, bearing flowers of a lilac-mauve with yellow eye, much like *Michaelmas Daisies*, during the summer months, gives a tint rare amongst perennials at that season. The single herbaceous *Pæonies* (*albiflora* and *Emodi*) are very lovely when cut, as are some of the less double tree *Pæonies*. *Doronicum plantagineum* *Harpur-Crewe* should be extensively cultivated, its large yellow stars being unique during the spring months. Many of the *Poppies* are most graceful in form and attractive in colour, one of the best for decoration being the single white *Opium Poppy*, which is most beautiful when artistically treated, though the flowers being very fleeting, the arrangement has to be renewed at least every day. The giant *Oriental Poppy* (*P. bracteatum*)—which at the time of its blooming is the cynosure of the garden—brings summer within the house with the glow of colour of its flaunting scarlet blossoms. The white *Everlasting Pea* (*Lathyrus latifolius albus*) must not be forgotten, as it produces a long succession of snow-white flowers, while the brilliant yellow *Coreopsis grandiflora* is most valuable for cutting and affords a lavish display of blooms; in fact, so extravagant of its beauty is this perennial that it oftentimes flowers itself to death, and a supply of seedlings should therefore be raised annually to keep up the strain. *Bocconia cordata* is very effective where a tall subject is needed, the flower-spikes being easily cut to a length of 7 feet or more. It associates well with *Kniphofia Uvaria*, the scarlet and gold of whose gorgeous flower-heads are set off to advantage by the neutral tints of the *Plume Poppy*. *Gypsophila paniculata* should be largely grown, as the light lace-like effect of its diminutive flowers and hair-fine branchlets harmonise charmingly with almost every form of floral decoration. The stately *Hyacinthus* (*Galtonia*) *candicans*, with its spire of white bells, should on no account be omitted, nor should *Salvia patens* or *Lobelia Queen Victoria*, which are valuable on account of their intense colouring, though the blue blossoms of the former are not very lasting, and the latter often proves difficult of management when permanently planted in the open. Herbaceous *Phloxes*, especially the dark red and white forms, should also be extensively cultivated, and perennial *Asters*, of which *Robert Parker*, large, light lilac; *Harpur-Crewe*, white; *Archer-Hind*, mauve-purple; and *ericoides*, which produces a profusion of tiny white Daisy-like flowers, may be recommended as well adapted for cutting. Of the perennial *Sunflowers* there are many varieties worthy of cultivation, *Helianthus latiflorus* being one of the best, though the new *Miss Mellish* bids fair to usurp the premier position. *Pyrethrum uliginosum*, with its large white, slender-rayed stars, is much sought after, being far superior as a cut flower to the less graceful *Chrysanthemum maximum*, which, being slightly earlier in blooming, should not be entirely neglected. Another most effective white autumn flower is *Anemone japonica alba* *Honorine Jobert*, which, when well cultivated, grows to a height of 4 feet and provides a wealth of large white single blooms for the flower basket. A little grown perennial which does well in the same position as *Amaryllis* *Belladonna* is *Erythrina crista-galli*, whose long racemes of coral-red blooms are very serviceable when little of that colour is obtainable from the garden.

Of biennials, the white *Foxglove* and the *Hollyhock* are, perhaps, the most valuable, the former the more so owing to its white spikes being more easily handled and arranged, as well as to its immunity from any constitutional disease, which in the *Hollyhock's* case, unfortunately, often renders it anything but an object of beauty. I have, however, at times seen tall *Hollyhocks* used with marked effect for indoor decoration, and

some should certainly be cultivated, seedlings grown on vigorously being less likely to succumb to the disease than plants raised from cuttings. In annuals, of *Sweet Peas*, of which there are now many new and lovely named varieties, it is difficult to have too many, while of the giant strain of the single *Sunflower*, both the golden and primrose varieties are absolutely necessary. The yellow *Paris Daisy* *Etoile d'Or* should be grown from cuttings, which will develop by the autumn into bushes carrying hundreds of large pale yellow flowers, shapely in form and delightful in colour. *Field Poppies* are great favourites for arranging in bowls and vases, and a good breadth of these should be cultivated.

Three subjects there are that, unless under exceptional climatic circumstances, will not be likely to produce cut blooms in the open. Where, however, they will flourish, and there are to my knowledge such favoured spots in the British Isles, the beauty of their flowers for indoor decoration will be admitted by all, though, being generally cultivated as pot plants, their blossoms are rarely used in floral decoration. They are *Canna iridiflora* *Ehmanni*, with *Musa*-like foliage and clusters of rose-pink flowers, *Agapanthus umbellatus*, both blue and white, and *Crinum capense*.

The foregoing notes do not pretend to be exhaustive in the matter of flowers for cutting, and it will occur to the most superficial reader that many beautiful and decorative favourites have not been touched upon. All the plants alluded to have been grown by me, and their flowers used for indoor decoration with satisfactory results.

S. W. F.

#### STOCKS.

WHATEVER may have been the harm done in some directions by the long summer drought, at least *Stocks* of many sorts have not suffered. I have rarely seen more beautiful shows of these flowers than have been furnished in some of our cottage gardens, where they seem to have done wonderfully well and to have bloomed profusely. Of course huge masses of these *Stocks* are often seen in seed grounds, and brilliant displays of them in large gardens, but never do they seem so thoroughly at home or so in accord with the surroundings as in a nice cottage garden. I came across many such gardens in Surrey during the past few weeks. One at *Coulsdon* facing the high road had broad borders, in which, mingled with other plants and flowers, pyramidal and branching *Stocks* of many colours were blooming abundantly. In the background stood the cottage, the windows aglow with well-furnished window boxes and plants in pots, whilst from the rustic verandah drooped festoons of *Canary Creeper*, or it formed arches encasing the floral decorations of the windows. Small tubs filled with *Creeping Jenny* and *Fuchsias* in the centre stood here and there on slight pedestals in the garden, the creeper covering the tubs and hanging down in graceful profusion. It was indeed a charming cottage flower garden, and well might the owner (an engineman) have been proud, for he seemed to be a true floral artist. In greater or less degree I have seen *Stocks* in exceeding beauty, and they literally filled the air with their rich aroma. How pleasant it is to realise that from a packet or two of seed sown under glass in the spring such a wealth of beauty can be thus easily produced. It is difficult to understand why the once highly favoured *Brompton* and *Queen Stock* should now be so seldom seen. Have we partly lost the old forms, for they are so seldom grown in gardens? Have our recent winters proved too destructive for them, or is it that the facility with which *East Lothian*, intermediate, and summer *Stocks* can be grown has led to the comparative abandonment of the old varieties? If we have no other *Stock* that is so noble, indeed almost

grand in its fulness as is the giant Brompton, it is certain none others are so bushy and so profuse in bloom as are the Queen, sometimes called the Twickenham section. Purple is not always a pleasing shade of colour in the summer Stocks, but in the Queen it is rich and beautiful. How effective have big masses of this colour, as well as the white and scarlet, looked when in full bloom beneath the overhanging trees in some market orchard. Both they and the Bromptons withstood many a hard winter in the past, and they might again if the chance be offered. Without doubt last winter's cold was far too great for Stocks to withstand, Wallflowers even succumbing to the first wholesale. Still we may hope that all succeeding winters will not be so hard, and that many things not absolutely hardy may yet exist through them, even Brompton and Queen Stocks. I saw it was advised but a day or two since to make sowings of these varieties. That may be all very well if the plants are to be wintered in a frame, but even then they would show poor form next year. It would be much better were strong plants ready to be put out now, selecting sheltered places and soil that is not too stiff and water-logged, but rather dry; then, with ordinary care, plants may be wintered very well. With a fine strain of giant Bromptons some may be got into 6-inch pots and be left in a frame all the winter, but the finest spikes can only be got from strong, well-grown plants. A. D.

#### NEW CACTUS DAHLIAS.

Two or three years ago it seemed as though the acme of perfection had been attained with the varieties just then raised of this the most lovely of all sections of that monarch of autumn flowers, the Dahlia. However, each season since the distribution of the varieties just referred to, Robert Cannell, Delicata, and others, our florists have raised novelties which are improvements upon their predecessors. The true Cactus form of the flower is too well known now to need description. In the introductions of the past few years we have at our disposal lovely flowers of almost every colour one can desire, so that for decoration we are well supplied. How far superior for this purpose are the Cactus varieties to their companions, the decorative Dahlias, or even to the singles! The latter are not so pretty in form, nor can they be considered so artistic, with their smooth round edge, whilst their petals will soon commence to fall. Of course the strong point against many Cactus varieties, and some of the most beautiful too, is their habit of growth, the flowers being produced on short stems and buried beneath a mass of foliage. This is a fault which also tells effectually against their use for garden decoration. But it does not exist in the case of many varieties, and will doubtless be in a few seasons eradicated from all varieties of the family which will then be in vogue. As a choice variety, possessing every quality which is deemed to constitute a good plant for this purpose, I would mention Matchless, which was distributed last year. It is of true Cactus shape, very free flowering, of medium size, with a tendency to be large, and of perfect habit, throwing the blooms well out of the leaves; the colour is well described as a rich velvety maroon. It also commences to flower fairly early in the season. Again, for cutting some of the current varieties are too large. On the whole, in the production of novelties it will be best to adhere to a medium-sized flower. That such is likely to happen would appear from the new varieties staged at the meeting of the Royal Horticultural Society on August 13. These also afforded ample evidence that there will be no falling off in the new Cactus Dahlias exhibited during the present season. Of those at the Drill Hall particular mention should be made of Mrs. A. Beck, an exceedingly pretty flower, in colour and size most suggestive of Panthea, but the petals well pointed

and the flower a perfect Cactus. The colour is a reddish salmon. The shape is admirable. Perhaps more attractive still was Arthur Cheal, larger than the above, and shown in fine condition. The colour is a very bright, fiery crimson-scarlet, reminding one of that of Major Haskins, but the outer petals are straight, not having the curve noticeable in the latter. This variety should become very popular. Other new varieties exhibited by Messrs. Cheal and Sons were Mrs. Gordon Sloane, of very novel and striking colour, pinkish terra-cotta, and Mrs. Broughton Stirling, rosy magenta, a pretty little flower with a profusion of very thin fluted petals. These two varieties will probably improve considerably before the end of the season. Mrs. Montefiore is also good. J. F. H.

**Notes from Baden-Baden.**—Lobelias of the fulgens class are showing flower. There are some good varieties, such as Queen Victoria, deeper in colour, Firefly, even brighter than fulgens, f. rosea, a very distinct variety, and Brun de Chataigner, a sort of maroon shade. I have raised a pale rose variety, and also violacea, of a striking violet colour. Gipsy, (Glow-fire, and Luna are good and distinct; the two former evidently have an infusion of the blood of L. Kerner; Gipsy comes near Queen Victoria, and Glow-fire near Firefly, but both have their spikes much condensed and better beset with a mass of flowers, thus showing a broad sheet of colour. Luna is an improvement on fulgens, having dense spikes of broad, full flowers of a peculiar shade of copper, or sort of glaucous scarlet. Both varieties of Incarvillea have proved hardy here; Vilmorin's had stalks up to 3 feet, and showed ten of its large blooms. Campanula mirabilis grows well. M. Cuisin's plate shows a wonderful pyramid of large lilac flowers 1 foot through, the foliage entirely hidden; it will prove a most remarkable alpine. Crocus Suworowi is one of the earliest, and a curiosity at the beginning of August; flowers white, with faint stripes. C. vallicola, which will open in a few days, is similar to Suworowi, only the flowers are larger and adorned with a few yellow blotches. As to Kniphofias, it is difficult to produce something striking, yet in Helios and Surprise I can show two splendid sorts. Helios since last year has much improved, and shows now its true character; it bears two enormous candelabrum spikes of an oval shape, orange-yellow. Surprise is an early flowering variety, the spikes very large, of a salmon-orange, a new colour among Kniphofias. A very striking and interesting plant is a new species of Berckheya carrying a bold raceme with large yellow flowers; the leaves, too, which are serrate, 2 feet long by 6 inches broad, are very ornamental; the upper side is strongly nerved and netted, of a deep shining green, and the under side of a pure creamy white. A group of these plants attracts attention from afar.—MAX LEICHTLIN, Baden-Baden.

**Effects of lime on Nymphæas and other plants.**—I have read the courteous reply from Mr. T. Smith, of Newry, in answer to my inquiry on page 98 of THE GARDEN. Mr. Smith writes that Nymphæas are all lime haters, and he holds out no hope of my being able successfully to cultivate these beautiful plants in my pool filled from a spring impregnated with lime. A curious instance of the antipathy of plants to lime has just occurred here. Having a plant in my rock garden of Androsace Leichtlini, I placed a piece of limestone underneath its trailing stems. A few inches below was growing a healthy plant of Asplenium septentrionale. I soon found out this plant was becoming yellow and sickly, no doubt from the rain-water washing over the piece of limestone above it. Near at hand I had other plants of the same Fern growing healthily amidst pieces of porphyry. I ought to have thought of this, as I have never found A. septentrionale growing wild except upon rocks of igneous formation. A. fontanum and A. lanceolatum are instances of this antipathy. A. fontanum will not thrive unless its roots are in contact with limestone, whereas to A. lanceolatum (its near ally) this contact is poisonous; it must

have a granitic or porphyritic rock. Acacia dealbata is a remarkable instance of this. In the gardens around Cannes it grows plentifully and luxuriantly, whilst but a few miles off, at Nice, under similar climatic conditions, it is stunted and unhealthy. In the latter case it is growing in calcareous soil on mountain limestone, whilst at Cannes it has decomposed granite for its sustenance only.—R. MILNE-REDHEAD, Holden Clough, Clitheroe.

#### ROCK GARDEN NOTES FROM KEW.

AT Kew Gardens the rockwork is interesting almost all the year round, but perhaps never more so than at the present time (August), when the flowers of the summer are practically past and the autumn flowers are not yet developed. It is the bridging over of the dull season that frequently presents some difficulty, and in this respect a good example is set at Kew, where many of the hardy plants are still as gay as can be desired. A short reference, therefore, to the plants blooming at the time of my visit (early in August) may help others in their selection.

That glorious Himalayan Poppy (*Meconopsis Wallichii*) still has its pale blue blossoms unfolded on stems quite 5 feet high, and occupies a damp, partly shaded position. *Gentiana asclepiadea* rears its dark blue flowers quite 2½ feet from the ground, and forms a good contrast with the white variety and also with the white *Symphandra Hoffmanni*, which, but for its connate stamens, would be scarcely distinguishable from a *Campanula*, having its large flowers disposed in a long raceme quite 2 feet high. Of *Campanulas* blooming on the rockwork, I will mention *Campanula haylodgensis*, a dwarf hybrid about 8 inches high, with pale blue flowers; the rare little gem, *Campanula excisa*, with deeply cut corolla and blue flowers; *Campanula versicolor Rosani*, which is pale blue with dark centre; and the well-known varieties *Campanula garganica hirsuta*, *C. pulla*, *C. pusilla alba* and *C. carpathica alba*. Alpine Poppies are mostly over, but I noticed the pretty little pale pink variety *Papaver alpinum roseum* still flowering profusely, as were also *Silene Schafta*, *Chrysogonum virginianum* and the bright crimson *Silene armeria*. Quite a gorgeous effect is produced by the showy annual *Erysimum Perofskianum*, which has large racemose heads of a brilliant deep orange colour, each individual flower measuring nearly an inch across; the leaves are lanceolate with a dentate margin, and the plant forms a most handsome bush quite 2 feet high. Another yellow flower of striking beauty is *Hunnemannia fumariaefolia*, a Mexican perennial with large, Poppy-like bright yellow flowers of great substance, springing from a compact mass of triternate glaucous leaves. The plant, from 1½ feet to 2 feet high, is most effective, but very probably requires protection during winter.

A very distinct and handsome Thyme is *Thymus comosus*, which is larger in all its parts than the better-known varieties and bears large spikes of pale pink flowers. Noteworthy, too, is a handsome dwarf plant under the name of *Coris monspeliensis*; it is only 6 inches high, has linear leaves reminding one of a *Sedum*, and bears elongated heads of pale purplish blue flowers.

On a prominent rocky ledge I noticed the graceful *Echium plantagineum*, which has its very small leaves densely crowded and is laden with red buds and deep blue flowers with red stamens. The plant is of elegant habit and well deserves the prominent position it occupies. Quite near the same rock *Tigridia pavonia* expands its showy flowers, and *Prunella grandiflora*

flora rubra, Erigeron aurantiacus, Hypericum olympicum and Polygonum affine make a good show of colour near a bog bed carpeted with *Pratia angulata* and the golden-leaved variety of *Lysimachia nummularia*. The Bead Plant (*Nertera depressa*) is used for a carpeting plant on higher ground, and the variegated *Sibthorpia europea* covers the ground of a level peaty bed. A delightfully showy plant is *Lamium maculatum aureum*; it forms a dwarf carpet of large, bright golden yellow leaves, suffused with white in the centre and setting off to great advantage the rosy purple flowers with which it is laden at this time of the year.

The only Androsace still flowering is *A. lanuginosa*, which is doing well, as is also the dwarf *Inula ensifolia*, with flowers resembling those of *Bupththalmum salicifolium*, but close to the ground. Of *Primulas*, I only noticed *Primula capitata*, with its globular heads of lilac blossoms; and of *Geraniums*, the varieties *Geranium cinereum lancastricense*, *G. subcaulescens*, *G. argenteum*, *G. Endresii*, and a dark blue form of *G. pratense* are still in bloom.

Rather interesting is *Erodium guttatum* with white flowers, showing a dark blotch on each of the two upper petals. (*Oenothera missouriensis* with its yellow flowers occupies a very prominent position, and close by *Polygonum sphaerostachyum* raises its blood-red spikes of showy blossoms quite 18 inches high. A little further on on the same side are the bright yellow flowers of *Potentilla bifurca*, the tall *Delphinium cardinale* quite 5 feet high covered with scarlet flowers, and the North American *Eupatorium ageratoides* with its compound corymbs of white flowers about 2½ feet high. Of *Anemone japonica* the variety now flowering at Kew is a specially dark and handsome one. Its neighbours are *Tradescantia virginica* and *Dianthus deltoides*, both in full bloom, as is also the elegant *Lythrum virgatum* with its crimson spikes and graceful habit.

In the foreground a prominent place has been allotted to the pretty white annual, *Alyssum maritimum*, while more in the background are *Potentilla fruticosa*, *Coreopsis lanceolata*, *Eryngium alpinum*, *Lysimachia barystachys*, and such stately plants as *Telekia cordifolia*, *Inula Helenium*, and *Hemerocallis fulva* var. *longituba*. The last variety is very distinct, bearing double flowers, which are deep red at the base, while the petals generally are deep orange.

As the foregoing names do not form anything like a complete list of the varieties now in bloom at Kew, it will be readily seen that though the summer is past, hardy flowers are still in abundance in these gardens, where no efforts are spared to provide instructive recreation for amateur and botanist alike.

Elmside, Exeter.

F. W. MEYER.

#### FLOWER GARDEN NOTES.

THE mention in last week's notes that the time had come when it was advisable to prepare for the propagation of those tender plants which still hold their own in flower garden arrangements brings the reminder that there are other flowers of much greater value which also demand attention, viz., those that are either perfectly hardy or only require sufficient protection to keep the frost out of the soil, and whose propagation can be effected in the open or in any ordinary pit or frame. Pinks, Carnations, Violas, and alpine Phloxes are already inserted, and in their respective quarters are progressing favourably; other things requiring attention later on are the taller Phloxes, both early and late, *Antirrhinums*, *Pentstemons*, herbaceous *Lobelias*, and the like. Any of these things represented at the present time by batches of seedlings will repay careful inspection, in order to ascertain what there is at once new

and good, and when something out of the common is found, to promptly mark it with the view to future propagation. I suggested in recent notes that very good things were obtainable from almost every packet of seed in several of the above herbaceous plants, that is if the seed was obtained from a thoroughly reliable source, and see something of the kind was specially noticed in a visit recently paid by the National Chrysanthemum Society to Sir T. Lawrence's seat at Dorking. Mr. Bain is reported as having two beds of *Pentstemons*, one of named varieties, the other of seedlings from seed sown in January, 1895, and an inspection of both resulted in the opinion that the seedlings were decidedly the better. Nothing could more fully substantiate the necessity of a careful inspection of beds of seedlings with the view, as I have said, of selecting the very best for propagation. In this way some special colour that is difficult to find among named sorts is often obtained. In the case of *Antirrhinums*, having fixed some plants of good constitution and the required height in different shades of white, yellow, and crimson, the same may be kept annually for special purposes and increased by means of cuttings, whilst for large beds where no particular colour is required, as also for forming clumps on herbaceous borders, seedlings may be employed. The propagation of early-flowering herbaceous plants, that is those that are out of bloom quite early in the season, may now be taken in hand. It is not necessary to do it thus early, but at the same time any work of this description that can be done at the present time will relieve the operations that are necessary with the general overhauling of borders, *Doronicums*, *Heuchera sanguinea*, and some of the hardy border *Saxifrages* being cases in point of plants that may be increased by division at this season. I have grown *Heuchera sanguinea* and *Saxifraga pyramidalis* together for the last two seasons on a narrow border that was formed in front of a wall on which are climbing plants in variety, and they make a brave show in such a site at their respective seasons.

**SUNFLOWERS.**—The varieties of *Helianthus* are strongly in evidence just at present. I put in several clumps of the miniature annual *Sunflower* to fill up a few gaps; these have developed into large bushes 5 feet in height and are now full of flower, whilst double forms are supplied by the perennials *H. multiflorus plenus* and *H. Soleil d'Or*. Both the latter are exceptionally good varieties for cutting, not so graceful perhaps as the single forms, but lasting longer in water. These, as a rule, continue in good health for many years when once established, but if there is the least indication that they are going back, the clumps should be lifted as soon as the foliage has died down, and the strongest pieces being selected, replanted in some good soil that has been deeply dug and well worked, incorporating a little good manure if the soil is rather on the light side.

**STARWORTS.**—The perennial *Asters*, or *Starworts*, are already with us, and as by the aid of an extemporised covering to keep off severe frost we are usually cutting the late varieties until the beginning of December, the season of these beautiful late summer and autumn flowers will be a long one. Sorts in flower at the present time are *acris*, some varieties of *Amellus* and *lavis*, *paniculatus* *Dot*, and *sagittifolius*. The last is not remarkable for the size or individual beauty of its flowers, but the fact that it throws a long graceful spike makes it very acceptable for cutting at the present time. One has to be a little careful in planting *Starworts*, to study in fact the flowering season, the height and the habit of different varieties. Thus, for instance, varieties of graceful habit, as *sagittifolius* or *diffusus* *horizontalis*, can be planted together in quantity and produce a very pretty effect; whereas very stiff and formal kinds, as *acris* or *densus*, look best in clumps of not more than two or three, with something lighter on either side of them. Writing of flowers for cutting reminds me to note how very late one of our very finest things, *Montbretia crocosmiiflora*, is this year, doubtless owing to the severe

frost in February last and their consequent late breaking away.

**SEEDLINGS.**—Boxes sown earlier in the summer with herbaceous plants in variety, tall, as *Delphiniums* and *Foxgloves*, of medium height, as *Pyrethrums* and *Aquilegias*, and dwarf, as *Picotees* and *Pansies*, will now be pretty well furnished with young plants, and it is advisable to get these shifted before the roots have too firm a grip of the soil. If convenient to transfer them to permanent quarters, this may be done, but if there is no room for them at present on the borders, they may be consigned to nursery beds for the time being and get their permanent shift later on. Perhaps the nursery bed is the best place while the seedlings are still small; one has them more under the eye here and can take measures to check the attacks of slugs, a dangerous enemy to the majority of herbaceous plants whilst they are yet in a young stage. It is well when pricking out to give the seedlings sufficient room to allow of a small hoe being run between the rows if the plants remain in the nursery bed until early spring. East Lothian Stocks, to stand through the winter, may be sown at once, if not already done. Autumn-sown plants that can be planted out early and get well established by early summer are more satisfactory than spring sown stuff in a very hot dry summer if facilities for artificial watering are not satisfactory. Self-sown seedlings of *Polyanthus* are coming up in their thousands where seed-pods were not removed. This is an easy and effectual way of securing a big stock of these favourite spring plants, and the seedlings can be the more easily removed if, some time before the seed ripens, the ground is lightly eased about 1 inch in depth round the plants, broken down, and a little fine soil added if this is deemed essential.

Claremont.

E. BURRELL.

**Lilium longiflorum Takesima.**—Occasionally among the vast numbers of *Lilium longiflorum* sent here from Japan during the winter months a distinct form crops up which may be readily distinguished from any other variety of *L. longiflorum* by the exterior of the unopened buds being suffused with purple, while the stem is also of a blackish purple hue, and the leaves are longer and narrower than those of the type. Its prominent characteristics are far more pronounced when in the bud state than they are after the flowers are expanded, for in this latter stage the purplish tinge of the exterior to a great extent disappears. There is no difference in the bulbs, hence it cannot be selected till the flower stem has pushed up. Though by no means superior from a floral point of view to the other forms, it is nevertheless interesting as an example of the variability to be found in *Lilium longiflorum*. Thus we have from Japan this particular kind, two variegated forms, a couple at least quite distinct from a floral point of view, and from Holland arrives the typical *L. longiflorum*, inferior in flower to all the others, while in addition we have the geographical form of *L. longiflorum*, sent here from Bermuda under the name of *L. Harrisii*.—H. P.

#### SHORT NOTES.—FLOWER.

**Tufted Pansy Purple Empress.**—This is a new variety thought highly of, and it certainly has rich colouring. The flower is round—too round for my own taste, for I think the circular bloom not distinct enough from the ordinary Pansy. It has a commendable habit.—H.

**Cactus Dahlia Gloriosa.**—It will be difficult to obtain anything of more perfect Cactus form or a sort of better growth than this. The colour is bright crimson-red; the petals long, narrow and twisted, forming a most handsome flower. The variety throws its blooms well out of the foliage, and the long foot-stalks enhance its value for cutting.—H.

**Effects of the drought upon tufted Pansies.**—Plants which passed through the late dry weather without being watered have responded surprisingly to the more recent rains, and are now a perfect mass of bloom, and uninjured by mildew, whilst those plants which had been constantly watered are badly affected with the disease, and also decidedly past their best in the matter of bloom.—H.

TREES AND SHRUBS.

WISTARIA SINENSIS IN DUBLIN.

THE illustration from a photograph by Mr. Greenwood-Pim shows a portion of a fine old Wistaria trained over a doorway in the College Gardens at Dublin. The specimen is about fifty years old and rambles over a considerable amount of wall space, and when covered with its pendent clusters of lilac flowers (as shown in the engraving) it is a very graceful and pleasing object. Seeing the time that has elapsed since this splendid climber was introduced from Japan, the wonder is that it is not more generally seen on walls and gables everywhere. Near London it is plentiful and flowers profusely, while one of the floral sights of April in Paris is to see the Wistaria on walls, pillars and iron railings everywhere. There is a fine plant scrambling over the grey stone gateway of Gabrielle's house at Fontainebleau, and one may see its purple festoons dangling over the

French gardens) deserves notice. In that country the walls are often devoted to the best of Pears and other fruit trees, but by stretching a single or double wire on iron supports 2 feet or so above the wall top the Wistaria is trained thereon, and thus becomes a very beautiful feature in town or villa gardens.

F. W. B.

**Last winter's message to the trade.**—I have been greatly struck at Ventnor with a point which should be of some interest to the nursery trade in the south of England. I refer to the wholesale destruction, approaching to extermination, of the shrubby Veronicas in particular. The green Euonymuses are all right, but the gold-edged ones are much damaged. The peculiar charm of these south coast resorts lies in these unusual shrubs. At Ventnor the Veronicas were as wild and common as in South Devon; now they are gone. The trade should, therefore, propagate these things freely, and everyone from the town authorities to the cottager should purchase and replant at once. Large owners of seaside property should supply shrubs gratuitously; in-

has nearly the entire panicle composed of sterile flowers, and the substitution of four large petals in place of stamens and pistil renders it a closely-packed pyramid of white flowers upwards of 1 foot long. The ordinary form, whilst less striking, is more graceful than the other. Its lighter panicles are more largely made up of fertile flowers, but the sterile ones are considerably larger than those of grandiflora, some measuring upwards of 2 inches across. The leaves are borne in pairs, or more frequently in threes, at each node; they are ovate, pointed, and covered with pubescence. The species is a native of Japan, and was introduced in 1874. It can easily be increased by cuttings taken before the wood becomes hard.—B.

**Spiræa Douglasi.**—For trimly kept beds and shrubbery borders there are numerous other Spiræas which are preferable to this, its strong, thick habit and somewhat aggressive mode of growth making it rather troublesome to keep within bounds. For the wild garden, on the other hand, and in fairly open woodland it is an excellent shrub, forming dense masses of erect, slender, Reed-like stems, which in July and August are each crowned with a dense panicle of bright rosy flowers. It is then particularly handsome and effective. The leaves are narrow-oblong, toothed towards the point, deep green above and whitish beneath. Its vigorous habit renders it suitable for almost any position; even in dry, sandy soil it will thrive better than any other Spiræa. It is, however, when planted in the vicinity of water that it reaches its full luxuriance, and may then be seen 6 feet or more high with panicles of proportionate size. It is a native of North-west America.—B.

Wistaria sinensis over a gate in the College Botanic Gardens, Dublin. Engraved for THE GARDEN from a photograph by Mr. Greenwood-Pim.

KITCHEN GARDEN.

HERBS FOR WINTER USE.

**PARSLEY.**—This is in great request in most places the whole year round, often more so during the dull months of winter, when it is not always easy to keep up a supply, hence the necessity of making provision while there is yet time. In many gardens sufficient attention is not paid to the growth of this useful herb, for often a sowing made alongside a path in spring has to suffice for the whole year. Here the plants are allowed to overcrowd each other through the summer, and by the time frost sets in the foliage has become so drawn and tender that a few degrees kill

windows at Hampton Court in a simple and pretty way. There used to be a white-flowered variety there also, near to the great Vine. Even if the Wistaria was not such a fine flowering shrub, it would be well worth growing for its wreaths of foliage so variable in colouring, from the fawn-tinted young leaves of spring to the golden coloured ones of autumn.

Travellers in Japan tell us of the wonderful beauty of the Wistaria as there grown in the temple gardens or around the most popular tea houses of that charming land. There are six or eight species wild and cultivated in China and Japan, but perhaps none better for our climate than *W. sinensis* and its seedling varieties. One reason why the Wistaria is rarely seen is that it is a slow grower in its earlier stages of existence. It is best propagated by layering the long shoots or branches in the ground under stones, and in this way strong young plants may be obtained. Once well planted in deep rich gravelly soil, all it requires is training occasionally and ample wall space. One way of training this plant (as adopted in

deed all that can be done should be done. Some more likely things not hitherto tried should also be added. The hardy Fuchsias have also suffered.—ALFRED DAWSON.

**Weigela Congo.**—This must be included in the list of persistent flowerers, for it is now laden with bloom, and still carries a great number of unopened buds. It is one of the darkest coloured of any, the blossoms being of a deep claret-crimson tint, but in a mass it is decidedly less showy than the brighter *Eva Rathke*. The large white stigma just protruding from the mouth of the flower is very conspicuous against the dark crimson petals. This variety forms a bold, strong-growing bush, somewhat in the way of one of the oldest of these crimson kinds—*Lavallei*, but the blossoms of Congo are deeper than those of the other. In both of them the flowers do not expand so widely as those of the *W. rosea* class.—T.

**Hydrangea paniculata.**—This is undoubtedly one of the showiest of all autumn-blooming shrubs, and is not only a sure flowerer, but also quite hardy—at least in the London district. Of the two forms in cultivation the one known as *grandiflora* or *floribunda* is more popular. This variety

it to the ground, thus causing a blank till growth commences in spring. To have a good stock of healthy fresh leaves it will be necessary to make two or three sowings, one in spring to give a supply during the latter part of summer and autumn after those plants which have withstood the winter have gone to seed, another in June to furnish plants for transplanting at the present time, and a third in August to provide a stock for spring and early summer use. Plants raised from the June sowings will now be large enough for transplanting. A piece of light dry soil in a sheltered situation should be selected, for on such the plants do not make such sappy growth as they do on rich retentive ground. A distance of from 9 inches to a foot should be allowed between them, as this will prevent the foliage from being drawn up too spindly. Should the weather be bright after planting, shade for a few days to prevent undue flagging, after which no further care will be needed till the approach of frost, when a temporary frame should be put round so that lights may be put on in case of severe weather. In some places snow will protect the plants from frost but in low-lying damp situations the snow melts thus leaving the plants exposed to the severity of

the frost. Not much protection is required, for the plants being grown hardy are better able to resist the cold, but in case of long-continued frost it is well to cover the lights with short litter during the time it lasts to prevent the leaves from getting frozen, for nothing has a greater tendency to destroy plant life than that of denuding it of its foliage when frosted. Plants that were left in the seed rows should be thinned to a distance of a foot apart, so that the foliage may have ample room to develop. That from the spring sowings may be cut and dried, as it will be too tender to withstand the frost, and such will be found very acceptable for flavouring soups, &c. Sowings made in August should be thinned to 6 inches apart as soon as the plants are large enough to handle: this will induce them to be hardy and dwarf, and at the first approach of warmth in spring they will start into growth, or they may be hastened by having portable frames put over them. Spring sowings are always better for being thinned early, as the foliage is then induced to grow more robust, and therefore stands much better when used for garnishing. Varieties are said to be very numerous, but any good strain of curled may be grown, and those who are desirous of saving their own seed would do well to plant a few roots of the dwarf and Moss curled by themselves, in order that a true stock may be obtained. The Fern-leaved varieties are very pretty for garnishing, especially when well grown, as the leaves are then more robust and do not wither so soon.

**CHERVIL.**—During winter when the young foliage of Tarragon is scarce the leaves of this plant are often in great demand, and as the plants make but slow progress during the dull, cold weather, they should be encouraged to grow before frost sets in. A sowing made at the present time in drills 6 inches apart on a warm border will give a supply of nice fresh leaves for use during the winter. This plant is somewhat hardier than the Parsley, but it does not make such rapid progress, neither does it grow so well when transplanted; therefore the plants must be thinned to the proper distance where the seed was sown. On our heavy soil we usually allow 6 inches each way, as the plants are apt to become crowded. In addition to the leaves being required for soups, many use them to flavour salads, in which case they should be quite small, being cut off the same as Mustard and Cress. When grown for this purpose, frequent sowings should be made, as the plants if cut below the seed-leaf do not grow again.

**MINT.**—The green leaves of this are often in demand during winter and early spring, and roots are often dug up from the permanent beds to give a supply. It is, however, not generally known that this plant can be propagated from cuttings of the young shoots at this time of the year, and if these are inserted in pots and stood in a cold frame they will continue growing through the winter. If wanted in greater quantity, the pots may be plunged on a slight hotbed, when young growth is quickly made. No garden, however, should be without a good supply of permanent plants, and no time could be better than the present for making new beds; therefore those desirous of increasing their stock may do so either by cuttings of the stems or by dividing the roots. If the former mode is adopted, insert the cuttings about 3 inches apart and keep shaded till roots are formed; when by the latter mode, select some of the strongest young roots and plant them in rows 6 inches apart; they will become well established before winter and start into growth early in spring.

**SAVOY.**—The winter or perennial kind may now be propagated by cuttings inserted in a cold frame, where they can remain till spring, to be afterwards transplanted into their permanent quarters. It is also well to plant some of the established plants where they can be protected in case of severe weather, as many suffered last winter owing to the frost. Plants of the annual or summer Savory should be taken up and dried for winter use before the season gets too far ad-

vanced. When dried it is better to preserve the leaves in close drawers to retain their flavour.

**BASIL.**—There should be no difficulty in keeping up a supply of nice fresh leaves during the summer, for if the seed be sown on a slight hotbed in spring plenty of plants will be produced for transplanting to the open border when the weather is favourable, but to have this green through the winter months is by no means an easy task, for, like many other such plants from the East Indies, it requires special care. As the green leaves are in great request in some places, gardeners are often called upon to produce them; therefore, preparations should be made in time. Sow the seed thinly in boxes filled with light, rich soil, which should afterwards be placed on a slight hotbed near the glass. When the plants are about an inch high prick them off into other boxes and return to the hotbed, keeping them as near the light as possible. As the nights get colder the boxes should be removed to the Cucumber house and kept near the glass, where they may have all the light and air possible. Plants so treated will usually grow sturdy and give a supply of leaves through the dull months.

**THYME.**—Most of the old plants were destroyed in this district last spring owing to the long spell of frost, and those who had not taken the precaution to insert cuttings in a cold frame ran short through the summer till plants raised from seed were large enough for use. It is advisable to put in a supply of cuttings each autumn, for by so doing the old plants can be cut hard back for use, there being no fear of the stock being lost. Cuttings should be inserted thickly in light sandy soil in a cold frame, to be transplanted in spring to where they are to remain. Plants so raised are much more forward than those from seed sown in spring, and the trouble in propagation is no greater.

**SAGE.**—This is also in great request during the autumn and winter months; therefore a good stock should be grown in all gardens. Last winter was so severe that many plants were killed, and others suffered so much that they had to be cut back to the old wood. Where the stock is short cuttings may be inserted in frames to provide a supply of plants for putting out in spring.

H. C. P.

**Cauliflower Pearl.**—Owing to the drought there have been complaints with regard to this Cauliflower. I note "C." (p. 65) recommends it to follow the Walcheren, and as it may be termed a dwarf selection of that old, well-known reliable variety, it is well adapted for summer work, the heads, though not large, being pure white and of delicate flavour. The growth is very distinct, being close to the soil, the leaves protecting the heads well. It is in my opinion the very best type of Cauliflower for summer use. Sown in March, and again six weeks later, there will be a succession of good heads from July till September by making several plantings. I do not know of any variety which stands drought so well as the Pearl. If required early a pinch of seed sown in heat will give nice heads in June, but its chief value is for summer work.—G. WYTHES.

**Potato Duke of Albany.**—Some little time ago a capital reproduction from a photograph of the above-named Potato, accompanied by a brief note, appeared in THE GARDEN, and at this season of lifting early varieties I should like to add a word in its favour. I have just finished lifting it, and the crop is very heavy and quite free from disease. The proportion of small tubers is exceptionally small, and the yield averages a little over 10 tons to the acre. Some few years ago I discarded all other early varieties in favour of this, and grow it now alike in pits for first crop, under south walls for second, and on borders for general digging. The particular border from which the bulk of the 1895 crop has been taken was for the three preceding years in Strawberries, and on deciding to remove the latter last season I left all old plants, runners and surface mulching on the ground, chopping them to pieces with a sharp spade.

When digging was in progress, the instructions were to get out a good trench, to dig deeply, and bury the rubbish well, leaving the surface as rough as possible. The ground worked splendidly in March after the long frost, breaking down like a bed of ashes right away to the partially decomposed rubbish. The latter afforded a capital aid in retaining moisture, and as a consequence the haul came away without a check, feeling nothing of the prolonged spell of drought. I would particularly recommend this Potato to the attention of cottagers and allotment holders; it is not only a grand cropper and of excellent quality, but the fact that it can be lifted so early in the season enables one to fill up the ground with a batch of Coleworts, late Savoys, Spinach or winter Onions. The only Potato that equals it in earliness and cropping qualities is Early Puritan, but this, especially in damp seasons, is not with me equal to the Duke of Albany in quality.—E. BURRELL, *Claremont*.

**The "sleeping" disease in Tomatoes.**—"B. C. R." (p. 61), in his notes from Worthing, speaks of this disease as obscure in character and difficult to deal with, attributing it to an excessive amount of iron in either the soil or the water employed. The disease is in reality caused by a fungus—*Fusarium lycopersici*, the resting spore of which attacks the delicate root-hairs and rootlets of the plant, finally invading the whole of the roots and spreading up the stem. The treatment recommended is that directly a plant is observed to droop it should be pulled up and burnt; the earth also in which it has been growing should be removed and mixed with quick-lime. This is seemingly the only way in which the spread of this disease can be checked.—S. W. F.

**Good dry season Peas.**—Up to the end of June was very trying for Peas, and many gardeners felt relieved when other crops like Scarlet Runners and Vegetable Marrows became plentiful. Out of about a dozen varieties sown during May only two have produced really good crops, viz., Duke of Albany and Autocrat; these two have been our main stay the last half of July and the early part of August, bearing first-rate crops of well-filled pods. In ordinary seasons John Bull, President Garfield, Laxton's Fillbasket, and Veitch's Perfection have always proved reliable croppers in July and August, but this year on our hot soil they may be termed a comparative failure, the growth being short and weakly, with few pods that were not well filled with Peas. Not only have the two first named been a success on our light land, but also on that of a heavy character, for, visiting a friend in charge of a garden with a soil of the latter description, I was struck with the healthy and robust appearance of several rows of Peas, and on inquiry as to the variety, was informed that it was Autocrat, he further adding it was the best late Pea grown, and Duke of Albany was named as the most reliable midseason variety, thus unconsciously bearing out my own experience.—W. G. C.

**Carter's Elephant Runner Bean.**—This excellent variety deserves bringing more prominently before the public for its earliness, productiveness, and fine quality. Many of the runner Beans are too large and coarse and find little favour in the kitchen, but though the above variety is long in the pod (about 10 inches) it is neither thick, stringy, nor ill-shaped. As an exhibition sort it should take high rank, as its dark green colour and perfectly straight pods of handsome shape make it very attractive. Again, for home use or market its prolific character is very valuable, many of the racemes having eight and ten long Beans or pods, continuing the same all the way up the supports. Up to the present date (August 6) I have had daily pickings of very tender pods for nearly three weeks, while other varieties are only just ready for use, though sown at the same time under similar conditions.—W. G. C.

**Wasps.**—I was sorry to read at page 94 "W. G. C.'s" account of the number of wasps'

ests in his locality. In this district there are but few, although the great number of queens about in May led us to anticipate a similar plague to that of 1893. My opinion is that their numbers were lessened by several heavy, cold thunderstorms early in June, these occurring during the daytime when the wasps were away from home. At any rate from that date until three weeks ago I had only seen a solitary wasp now and then, although during the last week several nests have been taken. The young wasps seem small and weak, as though hatched late. Cyanide of potassium is used in this part for destroying nests, but as it is done in the daytime when numbers of the wasps are away from home, I think many of

it spreads about and springs up freely from self-sown seeds.

## ORCHIDS.

### ANGREECUM SESQUIPEDALE.

THE subject of the accompanying illustration is one of the most marvellous productions of the whole Orchid family, and when in good health and well flowered is strikingly beautiful. It is an erect-growing plant, the deeply-coloured, glaucous green leaves clasping the stem and

*Angreecum sesquipedale.* From a photograph sent by Lord Annesley, Castlevellan, Co. Down.

them escape. The old-fashioned plan of stifling them at night with sulphur and powder, using a piece of small piping for a gun, and digging them out afterwards has still much to recommend it. When the hole is in a perpendicular form I simply pour a little gas tar into it, afterwards stopping it with a piece of sod.—J. CRAWFORD, Newark.

**The Willow-leaved Gentian** (*G. asclepiadea*).—The cultivation of this hardy perennial species entails no trouble, and it is a pity that more do not grow it. When established it spreads into thick bushy tufts, which grow 2 feet or more in height, and quite one half of each shoot is a perfect wreath of deep blue flowers. We saw some charming tufts of it at Newick Park, where

arranged in a distichous manner. From the axils of these the flower-spikes proceed, and bear few or many flowers according to the size and health of the plants. *Angreecum sesquipedale* is a native of Madagascar, where it was first discovered about three-quarters of a century since, but apparently never introduced to cultivation, as the late Rev. W. Ellis first brought it to England and flowered it in his garden in 1857. Growing naturally on exposed and sunny positions on the tops of trees, the plants are said to be very free-flowering, but do not keep their foliage, this making the plants far from attractive. Under cultivation, however, the foliage, without being densely shaded, can be

sufficiently protected from the rays of the sun to prevent its being scorched, and so lost. As I have before shown in these pages, the atmospheric conditions that obtain in our Orchid houses are by far the most important points in cultivating the large-growing, distichous-leaved Orchids, and perhaps this applies more forcibly to the subject under notice than to many others. It requires, and must have, great heat, and the light must be continuous and clear, never keeping the blinds down longer than is absolutely necessary to prevent the leaves being scorched. This advice, however, is far more easily given than acted upon; it would be easy to treat a houseful of *A. sesquipedale*, but not so easy to give it a congenial home where so many other shade-loving kinds have to keep it company. Still there are usually light sunny places, such, for instance, as an unshaded end to most Orchid houses, and these should be chosen. Then it thrives in a good deal drier atmosphere than is required by *Saccolabiums* or *Aerides*, and may on this account be placed where the hot-water pipes are most plentiful or nearest the boiler, such dry places not suiting many other kinds. It will not do, of course, to go to extremes in this, though if kept well supplied with moisture at the root it stands far more drought in the atmosphere and thrives better in it than any other species that I am acquainted with. The pots should be deep and well drained, the roots of this Orchid delighting to run in straight lines. Often at the end of summer the air roots will be found to have caught hold of the stage if this be constructed of wood and to have run a considerable distance upon it, and I have more than once had great difficulty in removing large plants. Of course, we cannot afford them this length of root-run, but by using the deepest pots at command, the long roots are encouraged to a certain extent. Clean Sphagnum Moss and charcoal are the best material for the compost, and the former must be induced to grow during the summer, thus adding to the appearance and health of the plants. In repotting old specimens that have got leggy and bare below, the stems should be cut off to just below where the principal roots start and kept lower in the pots, or if this cannot be done owing to the roots not being plentiful, the stem should be allowed to rest upon the bottom and the space around it be filled with drainage. Even during winter a good deal of water is needed at the roots, as these are often active at this season, differing in this respect from the majority of those of the distichous leaved kinds.

Although the annexed cut shows the character of the flowers, a short description of these may not be out of place. The largest blossoms are upwards of 8 inches across, very solid and thick in texture, and of a shining ivory white. The nectary is elongated into a tail-like spur, and though the specific name implies a length of  $1\frac{1}{2}$  feet, I have never seen one longer than 15 inches. The plants usually flower in spring, and as soon as these are over the compost should be put in order, either repotting or surfacing, as may be necessary. It is certainly the finest species of *Angreecum*, and has been largely the cause of bringing the genus into repute.

H. R.

**Oncidium longipes.**—Though a very small-flowering kind and not very showy, this little *Oncidium* is usually much admired when in

blossom. It never fails to flower with me in a small shallow pan in the cool house, from which it is removed during winter and placed in the cool end of the Cattleya house. The light green pseudo-bulbs are small and grow closely together, and the flowers, which occur on short, erect racemes, are each about  $1\frac{1}{2}$  inches across, bright yellow, spotted and blotched with brown. The blossoms are produced during July and August and last several weeks in good condition, being very pretty for button-holes or sprays.—R.

**Cypripedium Curtisii.**—This handsome species resembles the *barbatum* section in habit, foliage, and flowers. The leaves are each about 8 inches or 9 inches in length, green, with dark blotches and lines. The spike grows about 1 foot high, and is deep purple in colour and hairy. The flowers are rather stiff in appearance, but very distinct. The dorsal sepal has a white border, the basal part lined with deep purple and green. The sepals are greenish, with purple lines and many spots, while the pouch is port wine colour, with very deep purple veins. This species requires great heat to grow it well and a shady, moist position. This was discovered in Sumatra by Mr. Curtis in 1882.

### CATLEYA GUTTATA.

THE various species and varieties that resemble *C. guttata* form an interesting group quite distinct from the *labiata* kinds. They are quite indispensable to a representative collection, and several of them are extremely beautiful. Possibly the showiness of such as *C. Mossie* and kindred kinds will always make these most popular, and rightly so, for although gorgeous in colouring there is nothing coarse or gaudy about any one of them. Still the *guttata* group, as it may be termed, will never lack admirers, and they give a pleasant change from those mentioned above. *C. guttata* is an easily grown plant, quite as easy as any in the genus, and if kept to a proper routine of growth it will not fail to flower satisfactorily in due season provided the plants are sufficiently strong. It must be afforded a light position, yet not too close to the glass, and a full Cattleya temperature must be maintained. I usually repot in spring just as it commences to grow, for the roots in the compost are just then becoming active. The compost must be used in a rough and open condition, good peat fibre broken in lumps as large as a Walnut doing well for large plants if mixed with half its bulk of Sphagnum Moss and a plentiful sprinkling of charcoal. The pots should be clean and rather more than half filled with drainage, this being protected by a film of rough Moss before filling in with the compost. As the new growth advances more water will be required than at first, and when nearly finished a number of roots will be emitted from the base of the forming pseudo-bulb. These are usually above the surface of the compost, and in order to keep insects away from them and convey them to the level of the pots a little new compost should be placed under and around them. This has also the effect of strengthening the plants, and it will be found that at this season the plants will require an abundant supply of water, more in fact than at any other time. It should be noted in repotting this class of Orchid that the roots are very vigorous and soon outgrow their pots; therefore give them room and keep the leads as near the centre of the pot as possible, for although the roots grow freely enough in the atmosphere, and doubtless collect much moisture therefrom, they are safer and better covered up. The more they cling to the inside of the pot the better, but outside they are exposed to many dangers. When the growth is finished and the flowers past, less water will be

required at the root, but the plants must not be dried up nor must the temperature be allowed to go below 55° at any time if it can be avoided. *C. guttata* in its best forms frequently attains a height of 24 inches to 30 inches, and bears at the apex of the pseudo-bulbs a couple of deep green leaves. From between these the flower-spikes spring, bearing few or many blooms, according to the health and vigour of the plant, ten or twelve on each being not uncommon. A good typical blossom would measure 4 inches or so across. The sepals and petals are yellow, tinged with green and bearing abundant small spots of bright red. This is a native of Brazil, and although introduced at several times under different names, has been known to cultivation since 1827. It is very variable, some of the best known variations from the type being

*C. GUTTATA LEOPARDINA*, which does not differ from the type in ground colour, but has spots much larger and not so bright in colour. The lip is bright and pretty, the central lobe being rosy purple, the side lobe enfolding the column being pure white.

*C. GUTTATA LEOPOLDI* is one of the most distinct and charming kinds in this section, of a robust habit and very free flowering. It was introduced from St. Catherine's Island, in Brazil, to the gardens of the late King of the Belgians, in whose honour it was named. The sepals and petals are chocolate with deep crimson spots, while the lip is deep rich purple and white. This is often classed as a distinct species, and a sub-variety, *odorata*, has been described as being heavily scented.

*C. GUTTATA PRINSI* is a smaller growing, but chaste and beautiful form, having petals nearly or quite pure white with a few faint spots of magenta or rose. The lip is bright crimson in front and very broad and beautiful.

*C. GUTTATA RUSSELLIANA* is an older variety, somewhat resembling *Leopoldi*, but the flowers are not so bright in colour or so plentifully produced upon the spikes. A native of the Organ Mountains, in Brazil, whence it was introduced in 1838. H.

**Vanda tricolor planilabris.**—This is a large flowering variety of this noble Orchid and a most beautiful plant. Although not by any means new, it is not often seen, and is really worthy of note. The habit is identical with that of the type, but the flowers are yellow with numerous brown spots upon the sepals and petals. These are very broad and of great substance. The lip is a bright rose with lines of deep purple. The plants must be strongly grown to induce them to flower, and a light position in a large spacious house suits all this section admirably. None of them require much heat in winter, this being in fact injurious, by stimulating the growth when it is not needed.

**Cypripedium Lowi.**—This very distinct and favourite *Cypripedium* is now in bloom. The flowers, large and singular in appearance, are produced in spikes of about four or five. These are variable in their colour and markings, the dorsal sepal being usually greenish purple: the petals are long and twisted, light green spotted with purple, and with purple tips, while the pouch is greenish purple and very glossy in appearance. It is a strong growing plant, bearing leaves each upwards of a foot in length, and requires the temperature of the East India house. Plenty of water must be given all through the year; therefore the compost must be free and open and the drainage good. It grows naturally on high trees in dense forests in Borneo and was introduced in 1846.

**Pleurothallis Barberiana.**—Where curious and interesting Orchids or plants of any kind are liked, this peculiar little species is sure to be admired. The flowers are very small, transparent-looking, with sepals like the wings of a fly spotted with brown. The stems which bear them are so fine as to be hardly discernible, and the least

current of air sets the flowers in motion. It is probably from this circumstance that it has been named the Gnat Orchid. It is a very small growing plant, a native of Colombia, and is best grown in company with the smaller section of *Masdevallias*.

## FRUIT AND VEGETABLE CROPS.

### SOUTHERN.

**Royal Gardens, Frogmore.**—I am glad to be able to report favourably of the fruit crops in this district. In the Royal Gardens we have excellent crops of all hardy fruits. Apples are above the average; in fact, this may be called a record year for this fruit. Pears are a good average; some of the trees are so heavily laden with fruit that severe thinning has to be resorted to. Peaches and Nectarines are excellent. Plums and Damsons average. Apricots fair crop of fine fruit. This has also been a record year for Cherries, the crop being the finest I ever remember. Bush fruit of all kinds is abundant and of good quality. Exception must be made in the case of Raspberries, which are small, but the crop is abundant. Strawberries excellent and of fine flavour. With reference to the question you ask as to the effect the past severe winter and the recent drought have had on the fruit trees and crops in this district, I cannot say that I have observed any special effect caused by either. At the same time I consider the question an important one, and well worth considering from the point of view you mention. Before doing so, I may perhaps be allowed to pass briefly in review the sort of weather we in this district have passed through during the past six months, noting, in passing, the great flood of November, 1894, the greatest flood of the century in the Thames valley. New Year's Day came in with 10° of frost, and the same every day for the first week, with occasional snow showers and bright, sunny days. The second week proved more wintery, with a minimum of 15° of frost. On the night of the 12th 2 inches of snow fell, and the following morning a steady thaw set in, and by the 15th all traces of the frost and snow had disappeared and mild, unsettled weather succeeded with heavy rain, which caused another flood, the second this winter. Stormy weather followed, and on the 22nd another fall of snow (2 inches). Afterwards to the end of the month the frost was very severe, the lowest reading of the thermometer being 22° of frost on the 28th; rainfall 2'60 (average 1'75). February came in with severe frost and 1 inch of snow, the cold being intense, 29° of frost on the 6th and 7th, 26°, 24° and over 20° being registered for many days in succession, and the mean temperature was probably the lowest on record in this district for February. During the first fortnight the thermometer in the shade only rose to 32° twice. The frost broke up on the 20th, having lasted from January 21, but the thaw was only partial, and frost again followed with more snow; rainfall 0'09, being the lowest here for at least twenty years. The first week in March was cold and frosty, with frequent snow showers, afterwards becoming much milder, with bright sunshine until the last week, which was stormy and unsettled, with heavy rain; rainfall 1'20. On May 1 we had 4° of frost, afterwards until the 23rd the weather was very fine, sunny and dry, with low night temperature and cold east winds, but no frost. On this date a heavy thunder storm passed over with a fall of 0'18 of rain. This was followed by a rapid rise in the temperature, and brilliant hot sunshine prevailed afterwards to the end of the month; maximum reading of the thermometer in the shade on the 30th, 84°; maximum in sun, 95°; solar glass in vacuum, 134. This proved the hottest day. The rainfall (0'36) is the lowest on record for May here excepting 1880. The fine weather of April and May continued throughout June, and with the excep-

tion of the last week in April, when 1.12 of rain fell, the drought has now lasted for three months. On the 12th and 13th we had slight frosts, but no damage was done here, though other districts suffered more or less. On the 26th a violent thunder-storm passed over, only 0.15 of rain fell here, but in other parts it fell in torrents; rainfall 0.39. Total rainfall for six months ending June 30, 1895, 6.11 inches; total rainfall for six months ending June 30, 1893, 6.2 inches. It will be seen from the above that there is very little difference in the rainfall between the memorable season of 1893 and the present up to June 30, but the fall for July up to now (28th) has reached close upon 5 inches, and has altered the complexion of the season and redeemed it in some measure from being classed with 1893. Thus within the short space of six months we have experienced a most unusual extreme of heat and cold, and the question you are asking now becomes an interesting one in view of the effect (if any) those extremes have had on our fruit trees and crops. The severe weather has, I think, proved very conclusively that the whole of our hardy fruit trees are capable of enduring any degree of cold which we may expect to be visited with in this county (at least south of the Trent) without injury. Our trees never flowered better or stronger than they did this spring, and certainly heavier crops all round than we are having this year could not be wished for (thanks no doubt in great part to the absence of the usual deadly May frosts), so that, as far as the health and condition of our hardy fruit trees are concerned, severe winters are evidently not inimical to their well-being. I must except the Strawberry from this evil—it suffered most severely—but I think the injury was caused more by the fearfully cold winds of February and March than by the severity of the frost; many of the plants were killed outright, but, luckily, enough crowns were left unharmed to produce an excellent crop. Another point the late severe winter has demonstrated is the perfectly useless and unnecessary work of covering Vine borders with material of any description against rain and frost in winter. Ours last winter had scarcely any covering on them at all, and certainly our Vines never started better or carried better crops than they have done and are doing this summer. I am now convinced that this protection of our borders, as it is called, is a useless waste of material and time. I remember on one occasion speaking to the late Mr. Wm. Thomson on this subject, and he assured me that he had discontinued the practice for years as being useless. These remarks only apply to mid-season and late Grapes.

I wish I could speak as favourably with respect to crops in the vegetable garden. Here, I am sorry to say, the effect of the severe weather has been most disastrous. Broccoli, Brussels Sprouts, Spinach, Parsley, Lettuce, Globe Artichokes, Coleworts, &c., are killed, and the garden at the end of March appeared as bare as a "fallow field," and I am afraid that no remedy can be suggested which will be effective to prevent the destruction of our vegetable crops by those occasional visitations of severe frost. As regards the drought, the chief lesson, I think, this has taught gardeners is the paramount importance of thorough cultivation in the shape of trenching, deep digging, and the liberal application of good farmyard manure where it can be had, with liberal surface mulchings of manure. By endeavouring to pursue this practice here we have suffered very little from the drought.—OWEN THOMAS.

**Claremont, Esher.**—The fruit crop on the whole is very satisfactory, although, taken individually, one or two kinds are thin. Apples are not the heavy crop we were led to expect, a continuation of very drying winds and the total absence of moisture all through the blooming season being, I think, answerable for a rather indifferent set. Useful sorts, notably Keswick Codlin, Warner's King and Wellington, King of Pippins, Blenheim and Cornish Aromatic respectively in kitchen and dessert kinds are very plentiful. The Apple maggot was troublesome, some

places especially having a very severe visitation. Apricots are thin, the failure here being doubtless attributable (the trees being on a west wall) to the damp sunless summer of 1894 and to a consequent imperfect ripening of the wood. Cherries, both dessert and Morello, were and are carrying capital crops. Black fly was troublesome early in the season, but we have kept it well in hand by the aid of quassia extract. Plums are a good crop, not so heavy as last year, but a very good average all along the wall. I never remember a finer set of Peaches and Nectarines; the fruit had to be removed in thousands—in fact, hard thinning has been practised to enable the trees to come through the long spell of drought without suffering to any great extent. Aphides and red spider were troublesome early in the season, but, as in the case of the Cherries, vigorous applications of the quassia extract soon settled the unwelcome visitors. Pears are not up to the average, the crop on cordon, pyramid, or old wall trees being very partial. Figs were cut to the ground despite a covering of mats, and the crop is consequently nil. Strawberries were a capital crop, early varieties being very fine; later sorts were, however, considerably handicapped by the protracted drought and the season was very short. Raspberry canes in the open were considerably damaged and the crop was proportionately small; in sheltered situations, however, there has been plenty of fruit. All other small fruits are far above an average, the crop of Gooseberries and Black Currants especially being very heavy. As may be inferred from the above notes, only two fruits, *i.e.*, Figs and Raspberries, were any the worse for the exceptional spell of weather experienced in February, and in the case of the latter, only where the canes were fully exposed to the winds. The long spell of dry weather has, however, seriously affected many things, and all the damage is not as yet apparent. With the possibility of a drought, I put a good mulching of heavy manure to all trees about the beginning of May, and gradually, rain being still conspicuous by its absence, watered as much as I possibly could all the choicer fruits that were carrying heavy crops, also Strawberries and trellis Gooseberries.—E. BURRELL.

**Syon House, Brentford.**—In this district most of the crops may be termed above the average. I do not think any trees suffered in the least from the severe weather last winter; indeed, I think it was a gain, as though the blooming season was retarded, it was the better for the trees, there being no late frosts to affect the bloom. Peaches and Nectarines are a very full crop, the trees free of disease and aphids and making good firm wood. The early American kinds, such as Amsden June and Waterloo, were gathered the middle of July, thus showing that severe weather has not retarded growth; the fruits were not quite so fine as in previous seasons, but later varieties promise well. Lord Napier and several of the newer Nectarines are very fine. Apricots are not a heavy crop. The trees are wonderfully healthy, and there has been less loss of branches than in previous years, showing that severe weather is not harmful if we get a dry winter. Cherries have been abundant and good; such kinds as Governor Wood and Bigarreau Napoleon have furnished grand crops and the trees are healthy. Black fly was troublesome just as the fruits were colouring, but by cleansing freely the trees are now in splendid condition; Morellos are carrying heavy crops of good fruit. I had one of the best Strawberry seasons on record. It is only fair to add I rely mostly on young plants, mulching early and watering freely. Royal Sovereign and Latest of All were the heaviest croppers, and good flavoured fruits of Noble were gathered the first week in June from raised south borders. Raspberries have been a full crop, and where well mulched and fed the fruits were large. Superlative is the best. Other small fruits, such as Currants, Gooseberries, have been plentiful and good and very clean. Plums are an average crop, a few kinds bearing very freely; standard and bush trees are bearing more freely than wall trees.

Apples and Pears are all one can wish, and though the severe drought has affected the Apples, causing some to drop, I trust the genial rains will assist in swelling up late kinds. All varieties are bearing well and the trees will benefit by being thinned somewhat. All of the Codlin type are cropping well and most kinds may be said to be a good average crop. Early Pears, I fear, will not be large; later kinds promise well. A few kinds, such as Beurré Bachelier, B. Diel, B. Superfin, B. Sterckmans and B. Clairgeau are above the average.

Vegetables have been good and plentiful; a few crops suffered badly from drought, Peas being a shorter crop than usual. Early Cabbage, though a little later, was very good and there were no losses. Marrows and Beans are abundant. The early Potatoes suffered from drought, being smaller than usual, but late kinds promise well. Cauliflowers and Broccoli have not been so good as in former years; the severe frost crippled some of the hardiest forms of the latter, and drought washed on the summer Cauliflowers.—G. WYTHES.

**Wrotham Park, Barnet, N.**—The winter here, or rather the latter part of it, was very severe and prolonged, lasting up to the end of the first week in March, but we escaped in a great measure the late spring frosts, as we lie very high. The drought too has been both long and severe, due also in some measure to our elevated position, many times there being rain round about us, but none falling here, the total amount of rain registered here for May and June being only 0.75 inch. Apples above the average. Pears average crop. Plums and Peaches below the average. Cherries below the average, except Morellos. Apricots good. Strawberries above the average, although after the first picking the rest were small and inferior, owing to the drought and heat. Red Currants good. Black Currants and Gooseberries average. Raspberries under average; plenty of bloom on the canes, but it set either very imperfectly or not at all, the dry hot weather being against it. Filberts and Walnuts over average. Figs suffered most from the severe frost; none of the other crops appear to be much affected by it. The light crops of Plums and Peaches, I think, were owing more to the heavy crop each carried last year, and the wood not perhaps being as well ripened as it ought to have been through the mild, damp autumn and early part of the winter. Kitchen garden crops suffered severely, whole breadths of Broccoli and Savoys being quite destroyed, while very few plants of Brussels Sprouts and Curled Kale survived. Phoenix Kale stood best of anything here and was invaluable. Three parts of the autumn-planted Cabbage were killed and had to be filled up with spring-sown plants. It was quite the middle of March before the frost was out of the ground. Carnations also suffered much, many clumps being killed outright.

Potatoes are small, though there are plenty of them to a root. Peas came in earlier, but soon failed, and the supply at present is very limited, many of the rows being badly affected with mildew now; the later sowings may be better now we have had a thorough soaking of rain. Cauliflowers have been poor and small, Spinach quite a failure for some weeks. Carrots, Onions and Beet all are smaller and more backward than usual, but there is plenty of each. Brussels Sprouts, Cabbages, Kale, &c., are later, owing to the fact that the plants did not grow very fast in the seed beds, and also that only a certain quantity could be put out at a time, as they had to be watered daily for some time after planting.—G. RINGHAM.

**Hanger Hill House, Ealing.**—Apples are a good crop. Pears generally are about an average, except Louise Bonne of Jersey, which with me is a failure. All kinds of bush fruits are abundant and very fine. Strawberries an average crop, but soon over on account of the drought. The latter with me was the only crop that suffered from the recent drought. Peaches and Nectarines are very good. I gathered a dozen fruits of Alexander on July 10 of good flavour. Plums, Damsons and Cherries are a good average. I never remember seeing fruit trees cleaner and

freer from insect pests. Fruit trees in general passed the late severe winter exceedingly well, especially after such a mild autumn and early part of winter.

Vegetables of all kinds are plentiful; winter stuff of the Brassica tribe could not look more promising.—D. COOPER.

**Kingston-on-Thames, Surrey.**—Having special duties which take me during the summer and autumn all over the county of Surrey, I have had ample facility for seeing the general condition of the fruit crop. Taking it on the whole, the present season may claim to rank amongst the best, for the general crop is, or has been, first-rate. It is somewhat remarkable, perhaps, casually looked at, that such a fine crop of fruit should have resulted after so comparatively cold and wet a season as was the summer of 1894. We, however, have to remember that most of the wood which carries fruit is formed two years previously, so that in reality we may be said this season to have been enjoying the benefit conferred on trees by the hot weather of 1893, the considerable rains of 1894 helping to plump up the buds, whilst the singularly abundant sunshine of 1895 did so much to help well the fruit. It is true there were, prior to the advent of the rains, complaints that Apples were falling, but the effect was advantageous rather than otherwise, for there is such an immense crop of Apples this year, and almost everywhere severe thinning was a blessing rather than otherwise. The rains came in time to help swell up the fruit on Apple, Pear, and Plum trees, so that we may well look not only for great abundance, but also for good, clean samples. That the present is essentially an orchard tree season there can be no doubt. Surrey is not a great fruit-growing county for market sale, but it is a splendid Apple, Pear, and Plum county all the same, and crops are heavy generally. In gardens, on bush or pyramid trees, especially those on the Paradise and Quince stocks, the trees may have been less able to withstand the drought than large, old trees. Still there seems to be everywhere such an abundance, that it is not possible to find room for complaint except in restricted cases. Hessele Pears are cropping most wonderfully, so also are other common sorts. It seems a pity that trees as healthy and robust of better sorts cannot be produced, but these qualities are not usually found associated with high table quality in Pears. Plums are more partial, it is true, in some districts literally breaking down the trees, in others quite thin. That is all the better, as no crop results in so much loss and dissatisfaction when we have a glut as do Plums. Sweet Cherries have been most plentiful and fine. They also ripened well, the dry weather suiting them admirably. Morellos on standards or on walls have been, and are, a wonderful crop also. Walnuts are a grand crop, and small Nuts everywhere very abundant. Raspberries have been good where the canes were spared by the frost. In many places, however, they were killed back by the severe weather in the winter. I saw at Ashted Baumforth's Seedling giving some of the finest fruits I ever saw, not even excepting those of Superlative, also in places very fine. Bush fruits, Gooseberries, Red, White, and Black Currants, have all been wonderful crops. It seems impossible they could ever have been heavier. The fruits also were fine, in spite of the drought, and ripened well. Even with dryness at the roots, sunshine plays a very important part in fruit production. It may be difficult to specialise sorts, but Whinham's Industry among Gooseberries, and Red Cherry and Baldwin among Currants, have been exceptionally fine. Strawberries, too, in spite of the drought proved to be a capital crop generally.

Indeed, with many could hardly have been better. On walls, Apricots were none too plentiful, but there are plenty of Peaches and Nectarines. Thus it is seen that, taking Surrey as a whole, it has been a fine fruit year. The result is largely to encourage those who propose planting fruit areas, for in such a highly favoured county they have but to wait with patience to find an assured reward.—A. DEAN.

**Coolhurst, Sussex.**—The varieties of Strawberry that bore well were Vicomtesse Héricart de Thury, Sir Joseph Paxton, President, Noble, and Keens' Seedling. British Queen, Loxford Hall Seedling, Waterloo, and Eleanor bore but very indifferently, as they have done in former seasons, and will now be discarded, as they were grown side by side, receiving in every way the same treatment as those that have carried splendid crops. Indeed there are few varieties at the present day of mere value than the three first-named sorts, taking all in all, for forcing or outdoor culture. Vicomtesse comes in well for dessert among the first earlies, and when the fruit gets smaller it is excellent for preserve making. Sir Joseph Paxton was finer than usual, every berry being large and beautifully coloured to the very point, a thing that does not always occur in ordinary seasons; but the great heat of June had a most beneficial effect on the fruit, there being moisture at the roots, retained by heavy mulching in the autumn, and then being well watered when in flower. President bore heavily too under similar conditions of culture. Noble also bore large well-coloured fruit, but soft and flavourless. Keens' Seedling is not so satisfactory in this garden as I have seen it in Scotland, where it used to hold a foremost place in the list grown. Our plants did not suffer from the severe winter, there being a dry open leafage, the result of a full autumn growth, which no doubt preserved the crowns, which broke away freely and were healthy all through the cropping time, with not the slightest trace of red spider. Black Currants were an excellent crop, being on a north border on deeply worked land, Black Grape, Baldwin, and Carter's Champion being especially fine. Amongst the Red Currants, Raby Castle has been the best, being large in berry and beautiful in colour. Raspberries have been, on the whole, much under an average crop, the canes of most varieties being nearly killed to the ground by the severe winter, and consequently there was no wood to carry a crop. These require deep cultivation of the ground before being planted, and then heavily mulched in the autumn to retain the winter's moisture. Autumn mulching is of much importance at all times, and doubly so when an unusually severe winter comes, followed by an excessively dry summer. Cherries, as a rule, do not seem to thrive here, for although young trees have been repeatedly planted, with a change of soil, still they will not grow in a satisfactory way. Plums are thin, but these bore heavily last season, and were no doubt to a certain extent exhausted, and the cold, wet autumn of 1894 did not give the trees much chance to recoup their strength to form fruit buds for this year. Angelina Burdett, Belgian Purple, Blue Gage, Coe's Golden Drop, Rivers' Early Prolific, Old Green Gage, Jefferson, Pond's Seedling, and Victoria are the varieties with most fruit this season. Blue Gage and Belgian Purple can be always relied on for a crop, and both are excellent Plums. Pears are thin all over with one or two exceptions, and one of these is that excellent Pear Pitmaston Duchess, which bears well every season. I am much disappointed with that fine Pear Doyenné du Comice. I have tried it in all forms, on the Paradise stock, the free stock, on the wall, and as a standard, all to no purpose. The soil here is a deep clayey loam, suiting fruit trees fairly well in general. Apples are plentiful, some varieties much more so than others, Cox's Orange Pippin bearing freely, and fine fruit too. Blenheim Orange, Ribston Pippin, King of the Pippins, American Mother, and many more are bearing full crops, and the fruit is likely to be of a good size now that the trees are getting moisture at the roots. Apples in this neighbourhood are generally a heavy crop, but are likely to be small. Filberts are a good crop; Medlars better than they have been for several past seasons. Walnuts are plentiful and likely to be large. Indoor fruits are good.

Vegetables have not had the best chance, owing to the great drought of May and June. Cauliflowers poor, being open and thin. Peas got hard in a few days and were soon over; the late ones

are now likely to grow too much to straw, so that taking the year all through I fear it will not be one of the best of Pea seasons. Carrots doing well. Onions taken with the maggot. Potatoes quite free of the blight as yet. Early Puritan has been of excellent quality. This is altogether a splendid second early Potato. Lady Truscott is another fine second early, the quality resembling that of Puritan.—A. KEMP.

**Rickmansworth Park, Herts.**—The fruit crops generally have been good. Pears fair, Strawberries plentiful, but small, Gooseberries and Currants very good. The canes of our Raspberries were killed by the frost, but we are gathering some good fruit from the young canes, which are only from 1 foot to 18 inches high. The Morello Cherries are plentiful.

Peas and Cauliflowers have stood the long drought well, a fact I attribute to the deep working of the ground. Our land is very light and gravelly.—ADAM DUNCAN.

**Durdans, Epsom.**—The fruit crop here is fairly good considering the dry weather we have had up to the middle of July. There is still an average crop of Apples left on the trees, although a great many dropped off through the drought. Pears are rather under an average, Plums an average crop, Morello Cherries a good crop and the trees quite free of black fly with which in former seasons they have generally been infested. Strawberries have been a good crop, especially John Ruskin, from which we commenced gathering on May 30. Currants and Gooseberries have been an average crop, Raspberries rather deficient; the dry weather has told more on them than any other fruit crop. The Walnut trees are carrying a very heavy crop.—JOHN BARCLAY.

## GARDEN FLORA.

### PLATE 1029.

#### SCILLA SIBIRICA MULTIFLORA.

(WITH A COLOURED PLATE.\*)

THE Siberian Scilla has long held a foremost place in gardens as an early, easily grown spring-flowering bulb, and it was a popular flower long before the Chionodoxas, which latterly have been strong rivals to it, were introduced. The Chionodoxas, free and beautiful as they are, do not, however, possess that rich depth of deep blue which characterises and makes the Siberian Scilla such a bright and effective spring flower. Although its near ally *S. bifolia* is rather sportive, and the different forms of it vary in merit and beauty to some considerable extent, *S. sibirica* has hitherto shown little tendency to vary, but the variety illustrated in the accompanying plate differs in a marked degree in several ways, and is altogether a charming acquisition to spring flowers. Last autumn some bulbs were sent us for trial by Messrs. G. C. van Meeuwen, of Haarlem, under the name we here give, a name doubtless suggested by the remarkably free-flowering character of the variety, but at one of the spring meetings of the R.H.S. it was shown under the name of *S. sibirica taurica*, and was said to have been thus named by Mr. E. Whittall, who found it upon the Taurus Mountains. Its merits and beauty exist not only in its free blooming, but it is nearly three weeks earlier than the ordinary form of *S. sibirica*, of a distinct and rather lighter shade of blue, and even more robust, its long-stalked, many-flowered spikes being borne well above the ground and its own leaves. If one looked for the faults or failings of *S. sibirica*, the chief one would be found in its

\* Drawn for THE GARDEN by H. G. Moon at Graveyard Manor. Lithographed and printed by Guillaume Severeys.

*Primula veris* L. (Common Primrose)

short-stalked spikes, but such a charge cannot be brought against the variety here figured, which grows tall enough to gather, and is a truly charming acquisition in many ways. The plate appears at an opportune season, so those who desire to give it a trial can do so at once. It is equally, if not more, deserving of the esteem that has so long been accorded to the older form, and we shall be surprised if it does not take precedence of the two as soon as it becomes generally known.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**LATE PEAS.**—These, always a precarious crop, have of late years been rendered more so by our very variable autumns; hence the necessity for more pains in their culture. Valuable as a supply is through October, these late sown rows are very often neglected, especially where tall stakes are scarce. Vigorous growers, such as British Queen and No Plus Ultra, will in dry seasons soon drain the ground of all moisture, mildew making its appearance as soon through drought as through wet and sunless weather. Where ordinary stakes are in use and the haulm has ascended above them, rather cut it off at that point than allow it to fall down and so smother the young pods and blossom. By all means mulch thickly and give a copious drenching once in ten days with liquid manure, and where mildew has actually set in means must immediately be taken for its extermination. The recipe published in THE GARDEN last year is a most excellent one, and rarely fails to banish it if applied in time. It is as follows: To 3 lbs. of unslaked lime and 4 lbs. of sulphur add 1 gallon of water, and boil all together for 40 minutes. After settling, pour off the clear liquid and bottle. Use in proportion of from a quarter to half a pint in 3 gallons of soft water. Where the supports, owing to a scarcity, were placed too far apart, and the haulm is in consequence falling through, place some stout rods horizontally along the rows, tying them to the uprights here and there. The growth of the dwarf round-seeded varieties for a few very late dishes should be syringed with the mixture as a preventive against the disease, mulching and liberal supplies of root moisture being also attended to. Any odd rows having no more eatable Peas left on them should at once be pulled up, the ground hoed, and after being stirred and soaked, planted with Coleworts either of the Rosette or Hardy Green section.

**SCARLET RUNNERS.**—Although rain has at last fallen in most places, the quantity is insufficient to penetrate to the lowermost roots of many crops carrying abundant leafage. Few subjects draw the moisture from the soil sooner than Runner Beans, and nothing feels the evil effects of drought sooner. Hence the necessity for renewing the mulch on each side of the rows of those just coming into bearing, to say nothing of those now in full yield; and as on account of Peas becoming each week scarcer, their nearest substitute, Beans, will become more and more valuable, close gatherings liberal manurial drenchings, together with occasional baths from the garden hose, administered at eventide, must be followed up, even if hoeing and cleaning have to be temporarily suspended in order to accomplish it. Those grown on the topping system must be pinched and repinched as soon as fresh growth occurs, and where it is desirable to save pods for seed, the smaller ones in close proximity to them should be pinched off in order that the former may appropriate all the sap and attain to a good size before being harvested.

**ASPARAGUS.**—It is not yet too late to give another soaking of liquid manure or to apply some good artificial stimulant to this vegetable intended for lifting to force, and if the advice given at planting time to allow a 2-foot space between each three or four rows was followed, there ought

to be no difficulty in carrying out the work. If mulching also was practised when the plants were small, enough of that will still remain to preserve the moisture about the roots, and should there now be any weeds showing themselves, a little salt added to the manure will kill them. Although old permanent beds of Asparagus are now rather too densely covered with foliage to admit of getting amongst them, yet with a little pains the manure may be scattered broadcast, finding its way down to the roots through the force of autumn rains. This also has the effect of enticing a number of fresh fibres to the surface, which if slightly protected by a little rough litter in winter will lay hold of any actual top-dressing of loamy compost given in spring.

**FRAME CUCUMBERS.**—More care and attention must now of necessity be paid to Cucumbers growing in ordinary frames on manure beds, the nights and mornings now being much cooler than heretofore. The heat from the bed having for the most part declined, a renewal of it must be effected by building up fresh manure linings from 3 feet to 4 feet in width, allowing the same to come up to within a few inches of the frame top. Night coverings, moreover, must be given regularly, and earlier closing, say 2.30, on sunny afternoons practised. If these precautions are not taken, a sluggish root action coupled with stem canker and general debility will immediately follow, the fruit even if it sets failing to swell. Syringing must likewise be reduced to a minimum, choosing fine, sunny afternoons for the purpose. Keep the young growths well thinned out to admit abundance of light and air. Avoid overcropping.

**EARLIEST SEAKALE.**—Where the desire is to have this very early and a special sunny, open position was accorded the plants, they should now be gone through and freed from all weeds and rubbish, including decaying leaves, a maximum amount of light and air being necessary for the early ripening of the crowns. If occupying a sloping border and the plants seem in consequence to be rather dry at the roots, I would not advise watering now, as such might prolong the growing season, and it is not so much the size as the earliness of the first forced batches that is so important. All beds of Seakale for whatever purpose intended ought also now to be looked through, and if any more side shoots are visible, remove them.

**MIDSEASON TOMATOES.**—These plants now bearing ripe, ripening and green Tomatoes—the last in various stages—will require a little more consideration in order to give the fruit the best chance of finishing off with a respectable flavour; especially is this the case where the fruit is eaten in a raw state. Where practicable, turn on a little fire-heat to create a buoyancy in the atmosphere, and avoid afternoon damping down. This treatment is also needed to prevent the fruit from cracking badly and to ward off the disease, which is always encouraged by a clammy atmosphere. If the plants are fairly strong and have been well mulched, the use of manure water, especially in unheated houses, had better be discontinued. Any yellow or old leaves may be shortened back to render the circulation of air more thorough.

**SUCCESSION PLANTS.**—I have now a batch of plants bearing very small green fruit and bloom trusses. These occupy 8-inch pots, the limited space in which promotes a moderate and consolidated growth, just what is wanted for plants late in the season. These, although in an airy span-roofed house at present, will be removed in October to an intermediate one and stood along a back wall which receives plenty of light. They will there throw a most useful lot of fruit in October and November. Owing to these being in small pots they will benefit by a little feeding; this will be given in strict moderation, for the same reasons as quoted above. Small plants for actual winter cropping now being brought forward must be given all the light and sun possible, a sturdy, although by no means a rank, growth being especially necessary at this advanced period.

**WATERING CROPS.**—All spare time will now be best utilised in giving supplies of farmyard liquid to aid growing crops, except where from over-rich land these are too rank already. Newly-planted Coleworts should first receive attention, following on with late Brussels Sprouts, Broccoli and Kales. Celery will be much benefited by a supply of good rich food previous to the first earthing up being given, Globe Artichokes, Vegetables Marrows, Self-protecting and Autumn Giant Cauliflowers, and even pickling Cabbages deriving much good from one more good soaking.

**PICKLING ONIONS.**—Where these have been grown on poor land and are now giving way they may be drawn and removed to a cool, dry shed or vinery at rest to finish off previous to being pickled.  
J. CRAWFORD.

### FRUIT HOUSES.

**MELONS.**—These will now require more than ordinary attention, as with shorter days there will be less sun heat, which is so necessary for the welfare of the plants. With pot culture the cultivator can manage to give the plants the desired treatment at the roots, as in dull, sunless weather there will be trouble with canker owing to the sudden changes of temperature, excess of moisture, and overfeeding. A long period of hot, dry weather will have given what may be termed mid-season plants a good start, and they will now be finishing the crop, and at that stage require more care, as when the plants fail, the fruit, though fully developed, is poor and flavourless. In dull weather water must be given sparingly, and feeding should be discontinued when the fruits cease to swell, late feeding causing poor flavour and in many cases the cracking of the stems and premature decay. If the plants are growing on manure very little moisture will be required at the finishing stage. Overhead syringing must also cease in such houses. I do not advise premature drying off, as this affects flavour. Much depends upon the means at hand to finish the crop. With plenty of heat the plants should be kept healthy till the fruits are cut. Ripe fruits can be placed in a drier house when they show signs of cracking at the stem, and when ripened up on a warm shelf are much better flavoured. Should the house favour late growth and fruits take longer than usual to finish, it is well to air freely during the day and keep up a good temperature by fire-heat, 80° being none too much. With fire-heat there is difficulty with red spider, and it will be necessary to use sulphur freely, well coating the pipes and syringing the under sides of the leaves. I am aware this does not add to the appearance of the plants, but it need not remain long on the plants and fruit, it is soon washed off. For canker apply such remedies as freshly slaked lime with a portion of sulphur. Lime, sulphur, and fresh Portland cement will also check the disease if applied before the stem is too much decayed.

**LATEST MELONS.**—The plants will now be covering the trellis freely, and though good progress will have been made, the cultivator will have to take more care at this season to secure a good set and prevent crowding of foliage. It is well to aim at a thin crop, and to do this it is best to set the first flowers, stop early, and get a strong growth before the days get short and sunless. Plants in pots will take abundant supplies of food, as the top growth will be sturdier and the roots, being in a confined space, will need more nourishment. Plants with fruit just set should be top-dressed, using such aids as bone-meal and rough turfy loam. Keep the collars free of manure or rich food, and should canker (which is more troublesome with late plants) make its appearance, lose no time in applying the remedies advised for fruiting plants. Mildew will also have to be guarded against, and the free use of sulphur is the best remedy. Maintain a liberal temperature, allowing the thermometer to run up freely during sun-heat, closing at 1 p.m. and giving air sparingly.

**STRAWBERRIES FOR FORCING.**—Those who force early will now have their plants potted and the roots will be working freely. To plants in this

condition liberal supplies of moisture may be given and all runners cut off. I do not advise feeding till the plants have well filled their pots with roots, as I think early feeding tends to produce side growths or more crowns than the plants should be allowed to mature. Some varieties are much worse than others in this respect; for instance, Vicomtesse Hélicart de Thury splits up badly into several crowns if not checked. Early-potted plants placed thickly together when potted should now be given more room, the plants being frequently moved to prevent rooting through and to give them more light and sun all round. In feeding it is well to begin with very small quantities. Later potted-up plants will need more care than usual, on account of the heavy rainfall since the plants were placed in their fruiting pots. In many gardens late potting this season will have been unavoidable owing to the scarcity of runners. In placing late varieties in their growing quarters it will be well to give as much room as possible, and thus assist in securing quick root action, as the sun will have more play and the soil will dry up much quicker. A hard base should be given the pots, as worms soon do much harm to plants stood on walks or beds of soil. At this advanced period, failing a hard coal-ash bottom, it will be advisable to use boards or slates to prevent the ingress of worms. Plants only just potted up or ready to pot should have a size smaller pot than earlier or stronger plants, and if given the best position possible, they will yet make fair progress and grow till stopped by frost. Of course such plants will not be good for early forcing, but will give a good return for May supplies of fruit next season if the roots of the plants are well protected during the winter.

**VINES IN UNHEATED HOUSES.**—In favourable districts many Vines are grown in structures not heated, and up to the middle of July the weather was most favourable, but with much rainfall and loss of heat from want of sunshine, there will be trouble with mildew, as in many houses the berries were colouring when the change of weather occurred. When mildew appears it is well to take the disease in hand at once. Use sulphur freely, as the fruit will soon be spoiled if the pest is allowed to spread. A dry atmosphere must be maintained, all moisture being dried up early in the day, allowing a free circulation of air, and preventing drip or rain from entering the house. It is also well to remove any lateral growth, as by shortening this more air and light are admitted, and the walls may with advantage get a dressing of sulphur.

**WORNOU-T VINES.**—The above may include both old and young canes, as the latter are frequently much overcropped in their youth, with the result that the berries shank and the fruit does not keep long. With canes not too old and in outside borders much may be done at this season by renewing borders, partially lifting and preserving the small fibrous roots, and cutting back the old ones. The work should be done quickly, and the materials for the border prepared in advance. The old border up to the healthy roots should be removed with forks, and the drainage made good before the new soil is added. It is advisable to do the work piecemeal, so as to only expose a few roots at a time. In replacing the new soil it should be made as firm as possible, the fibrous roots being evenly spread out and kept near the surface. Avoid using animal manures. These may be supplied next season if required in liquid form. It is not necessary to make up the new border to the same extent as before. It will be best to make it up in sections at twice or more, according to the size. With Vines treated thus a little more attention will be required for a short time, the top growth being assisted. Keep the house close for a time, syringing several times daily, and should the Vines show signs of flagging, shade lightly during bright sunshine for a short time. Maintain a moist atmosphere till the Vines have recovered from the check. In a few weeks, more air may be given, the shading discontinued and syringing also, the Vines being gradually

rested. There should be no attempt to force such canes next season and they should be cropped lightly. G. WYTHES.

## ROSE GARDEN.

### AMONG THE ROSES.

AFTER the much needed rain, and this followed by warm weather once more, Roses are putting on a good promise of late autumn bloom. With the vast improvement among these flowers of late years we now have but very little break of bloom from the end of May until the close of September, often much later than this, but that depends entirely upon the autumn weather experienced. Both Hybrid Perpetuals and Teas are still in almost as full beauty as during the latter part of June—indeed, the latter are full of growth and bloom, while we get most delightful shadings in many varieties. Mme. Berard, Mme. Falcot, Marie van Houtte, Dr. Grill and others are far richer in colour than during the hotter and brighter days of early July. Gloire de Dijon, too, is as bright as we find Bouquet d'Or in midsummer. Eclair and a few of the dark velvety varieties, such as Duke of Edinburgh, Prince Camille de Rohan and Navier Olibo, produce grand flowers from the shoots made from the base since the early summer bloom was secured. Cool nights and dewy mornings aid these in point of depth in colouring, and if cut early in the morning they will stand quite twice as long in the house as summer flowers.

The change of weather from hot and dry to wet and cold for a period of two or three weeks has brought on mildew, but I am pleased to say that so far as my plants are concerned the new growths now forming are but little attacked. If we except the first part of our budding season, when the drought was not favourable to the lifting of the bark upon the stocks, I do not think we ever had a year in which there were better prospects of a good take. The buds inserted early will need loosening in all cases where a strong tying material was used, or the extra rapid swelling after rain will cause serious constriction. Both standard and dwarf stocks that are not already budded will now lift in grand form. Many that were not sufficiently strong before are fast gaining the desired size and strength, and this is particularly noticeable upon hedge Briers used in half and full standard forms. It will be well to go over these once more and bud those shoulders that were not far enough advanced previously. In many cases I have noticed plants of these have broken weakly, but as they are now making amends for this we must look over them again. Our dwarf stocks in more than one instance upon light and naturally dry soil were so weak that there seemed little prospect of being able to insert any buds this season, but their recent progress has been remarkable. I do not care for a strong stock to bud upon, as I have never had such good success in the union of bud and stock.

Many of the new growths now breaking so strongly from the base of dwarf Roses will need a stout stick as protection against wind-waving. These are of so much value that we may well pay a little extra attention to their preservation for next season's use. Last year I budded two each of the Hybrid Sweet Briers upon the Manetti and two upon the cuffling Brier stock. They were in the same row and had exactly similar treatment, but in every case, except Lady Penzance, those upon the Manetti stock are considerably the stronger. One of the most

pleasant features of my Rose garden is the delightful perfume thrown off by the charming Briers, which are soon to be increased in number and variation of colour. Some of the newer ones are very promising, but none more so than Jeannie Deans.

Once more do we find the forms of *R. rugosa* among the most pleasing and showy of all Roses. None are more constant or certain to please than these; they are never troubled with mildew or red rust—two of our worst enemies in the Rose garden. The hot and dry weather made little difference to them. Early this season a new *rugosa* from M. Bruant was figured in these pages. I have grown it this season and am much pleased with its distinctive character. M. Bruant advised me to cultivate it as a standard, and although I have not yet been able to get it in that form, its present appearance points very clearly to its adaptability for tall or short standards. The growth is equally vigorous, but not so stout as in *rugosa rubra* and *r. alba*, having a tendency to droop and developing this much more as the heavy trusses of berries mature. These are by no means so large, but far more numerous than those of the type. Instead of three to seven or eight, here I have from twenty to forty. It seems equally free from disease and is a great addition to this class. If we can improve upon the blooms and still retain the disease-resisting as well as the great value for town gardens found in *r. alba* and *rubra*, this class will rapidly become better known and appreciated.

The constant stirring of surface soil is not sufficiently practised after our first crop of bloom is past. For example, the recent heavy rains have beaten down the soil more firmly than many of us imagine, and it is at all times beneficial to keep the top soil loose and open to atmospheric influence. Even where the plants are mulched between with short manure I would prefer them to be worked among as far as possible. It has a great tendency towards healthy growth, keeps the whole plant in trim, as it were, and has much to do with ripe, well-matured wood for passing through the coming winter.

After these showers, with the ground so warm and genial, we can be almost sure of a successful strike of cuttings if placed on the partially shaded side of a hedge or fence. Use wood that is quite half ripe and insert it three parts of its length. A light, porous soil is best, but one of a heavy nature may be used if we are careful to place a little sand or woru-out potting soil at the base of the cuttings. These will root at once and be practically established before winter. Upon more than one occasion when very short of stocks for grafting I have made some cuttings early and inserted them in sandy loam. They soon rooted, were lifted in November, and potted ready for use by the end of the year. R.

**Autumn prospects.**—Seldom have these been more promising. With the ground very warm and dry, followed by copious showers, Roses are now bursting into new growth of a pleasing and healthy character. This, as usual, is more especially the case with Teas and Noisettes, also many of the Hybrid Teas. Viscountess Folkestone and Caroline Testout are again a mass of flower; indeed, as regards freedom in flowering I see little if any choice between these and the true Teas. The early growths of climbers, such as W. Allen Richardson, l'Idéal, &c., were so checked by the drought, that we have a much better matured wood than usual, and these are now fast coming into bloom again. Hybrid Perpetuals and the old favourite Bourbon, Souvenir de la Malmaison, are

also promising. On a wall the climbers are again coming into bloom, while the dwarfier growers that are placed alternately between these are already gay. Sunset, Marie van Houtte, Mme. Falcof, Anna Ollivier, Niphotos and others of like growth are equally as full of bloom as at the end of June. The careful and constant removal of all faded blooms has much to do with a succession of flower, and with a little surface culture there is no reason why we should not have Roses in greater profusion through the late summer and autumnal months. Teas and Noisettes are of course the chief bloomers: in fact, every season we see more to admire in these classes, and with the vast variety now to be had they are undoubtedly the most useful section of all.—R.

#### ROSES IN POTS.

To have these in the best condition during the coming winter we must commence now. Pot Roses in most cases have made good growth. It now becomes absolutely necessary to get the wood efficiently matured, otherwise there is little prospect of successful forcing at a time when we are receiving very little aid from the sun. I prefer ripened wood to start with, but, as usual, shall grow a few of the later worked plants without a check, and so get those flowers that would otherwise be caught by frosts. Some of our pot plants in the open are almost ripe enough already, but others are making a succession of healthy young growths, and will flower again before needing house room. At all times, in a batch of pot Roses, we can select plants in two different stages of growth. A few plants, kept as backward as possible upon the north side of a wall or hedge, will generally be breaking into new growth too late for safe blooming in the open, and if these be housed at the same time as the ripened plants are started, they will give us a welcome crop just previous to the latter. In ripening our pot Roses, we need to do so in as steady and natural a way as possible. If too hasty, the wood is not so sound as it should be, nor can we avoid considerable injury to the fibrous roots when artificially ripened by withholding water too closely. Much the best plan is to partly plunge the plants outdoors, this keeping the bottom soil fairly cool and free from a parching drought. Worms will penetrate unless we take due precautions. But this is so easy and simple, that there is no excuse for trouble in this direction. Simply place a small handful of soot at the bottom and stand the hole of the pot on this. No worms will come through, and you avoid the risk of stoppage sometimes found when a pot fits too true upon a piece of slate or other substance. When the pot is lifted, the soot will easily wash off during the usual cleansing of the pots before housing for forcing. Plants that were under hard forcing through the past winter have, of course, now been outside for some time. If potted up again now and then replunged, we shall soon have them starting into growth ready to produce useful flowers at Christmas and onwards. I am a firm believer in this plan of starting them very gradually in the open air during autumn, and then housing them just previous to frost. For some few weeks when first under cover they will need no fire heat, but it is very essential that they never get checked by cold; therefore some little care and judgment are needed in ventilation and the judicious use of a fire upon cold nights.

As soon as those Roses that were carrying flowering growth when housed have bloomed, they can either be removed to a cool pit or frame and allowed to complete their ripening ready to take the place of our earliest batch, or be retained if more promising growth is being made. It is easy to work two batches in this way, and as we can place the ripened and pruned plants close together, there is ample room for several to finish the crop of bloom that would have been lost outside. As this is secured, and the plants removed to the pit or frame, we shall have the desired space for our later batch, then fast breaking into

growth and needing more room. Cut flowers are equally valuable a week or two before Christmas, as at that time and after, when the first really sharp frost comes, our outdoor flowers are gone all at once, and then a few Roses that have been saved as described are much appreciated. The most important points are to prepare the plants with care, and never to hurry them too much when first housed. The protection of glass and shelter from cold air is a great change, and fire heat should be kept away as long as open weather lasts, or, at any rate, much longer than many practise. R.

### FERNS.

#### NEPHROLEPISES.

ALTHOUGH this genus is chiefly confined to the tropical regions, several of the species may be grown in an intermediate temperature, and during the summer they will thrive well in an ordinary greenhouse provided the atmosphere is not too dry. Few Ferns are so easily managed as the Nephrolepises. They can be readily increased by division, or the young plants which spring up from the slender spreading rhizomes or stolons. Some of the species produce tubers under ground, and from these young plants are produced wherever they can push through and find daylight. Besides the above mode of propagating, most of the species produce spores which germinate freely, the only exception in regard to spore-bearing being *N. Duffi*, which I believe has never been known to produce the slightest semblance to spores in this country, and I am inclined to doubt if it really belongs to the *Nephrolepis* genus.

The *Nephrolepises* like a fairly rich loamy compost. If the loam is heavy and devoid of fibre, some peat may be used, but good rough, fibrous loam, leaf-mould, and a little well-rotted manure will suit them well. Plants grown on from single crowns make the finest specimens. With age the plants get dense and tufted and the fronds too much crowded to develop to their full length; it is therefore advisable to grow on young plants periodically to replace those which have become stunted through age. Young plants will, of course, thrive best in a stove temperature, but when required for decoration they may be gradually hardened off.

The *Nephrolepises* include some of the most effective of all Ferns for growing in suspended baskets; they are also well adapted for elevated positions in the rock fernery, and as pot plants they are equally useful. Within the last few years some of the hardier sorts have been extensively grown for market, *N. exaltata* being the one which finds most favour. There is not a large number of species and only a few garden varieties have been added; this is probably owing to the fact that they are generally propagated by division instead of from spores, for I have found that when raised from spores they are inclined to vary in character quite as much as *Pterises* and others. This is particularly the case with *N. davallioides furcans*, from which we get a beautiful variety in *N. d. multiceps*, which differs from its parent in having narrower and more forked pinne, the fronds branch out more, and sometimes terminate in a dense tuft of finely-cut multi-fid growths. Another distinct variety is *N. d. plumosa*; although this is sometimes named *N. exaltata plumosa*, it is un-

doubtedly a seedling from *furcans*. Another pretty garden variety is *N. pluma Bausei*, differing from its parent in having the pinne irregularly forked and lobed; it is a most beautiful Fern, but being deciduous, it is not so well known as it deserves to be, and has probably often been thrown away as being dead when it had only lost its fronds in a natural way. The best way to keep the plants while dormant is to stand them in the stove and see that the soil is kept sufficiently moist to prevent the crowns shrivelling; they will then start into new growth early in the year and the soft pale green, feather-like fronds form a good contrast to the darker green of other sorts.

I have seen several slight variations in *N. exaltata*; the one I grow has much longer and more drooping fronds than some I have seen. *N. tuberosa*, which grows erect, is another useful Fern.

Of larger growing forms, *N. davallioides* and *N. ensifolia* are the best; both make very long fronds, and it is only when suspended where they have plenty of room that the fronds can develop to their full beauty. *N. rufescens tri-pinnatifida* when well grown is a grand Fern, but this is perhaps the most difficult to manage. It is only when young plants are started early in the year and grown on in the stove without receiving any check that it develops perfect fronds; the older plants rarely make good fronds, and even young plants if they have the slightest check will fail to perfect their growth and will have a distorted appearance. The normal form is also worthy of attention and grows freely, the fronds grow erect and attain to from 3 feet to 4 feet in height in quite small pots. This is sometimes confused with *N. Zollingeriana*, which is a much dwarfier Fern.

Of smaller forms, *N. pectinata* and *N. philippinensis* are both compact-growing species; the latter will do well in a low temperature, but *pectinata* should be grown in the stove. *N. cordata compacta* is another desirable variety; the fronds are of medium length, deep green, and stand up well, but are sufficiently recurved to give the plant a graceful appearance; this also makes a more symmetrical plant when grown from a single crown. I do not know the origin of this variety, but the name "cordate" is rather misleading, the pinne being more sagittate than cordate. *N. Duffi* (which I have previously referred to as a distinct Fern) is well worthy of attention. It is of erect growth; the fronds are slightly tasselled and droop over a little at the points. It is not often that it exceeds 18 inches in height, though I have seen it nearly double that height. It is only in a moist stove heat that it succeeds well. Though it does not make the long spreading rhizomes as in other species, it can be readily increased by dividing the dense tufts of crowns. I find this species succeeds best when potted in a lighter compost than that recommended for the more vigorous growing sorts. It is more adapted for pot culture than for baskets.

I may close this note by recommending the use of *Ficus repens* for covering the baskets. If a few young plants are put round the outside of the basket when it is first filled and pegged to keep them in place, by the time the *Nephrolepises* are well established the *Ficus* will form a nice green covering round the baskets.

The *Nephrolepises* require more water than many Ferns, and when the pots or baskets are well filled with roots, a little liquid manure or fertiliser may be used with advantage.

A. HEMSLEY.

## ORCHARD AND FRUIT GARDEN.

## A NEW MELON.

MELON Hero of Isleworth (here illustrated) was the result of crossing an early variety with one noted for rich flavour, its merits being its early fruiting qualities for a green variety, with its heavy crop. I think a good green-fleshed Melon difficult to beat as regards flavour, but it will not keep long. My aim was earliness with flavour combined, as in these days, when so much is expected from glass in a private garden, there is a great gain in growing Melons which mature quickly, as three crops may be had in one season. I admit flavour in new kinds is not always retained, but it is not always the fault of the variety, so much depending upon the culture. Rich soil with food at the wrong time causes loss of flavour. The best way to test the quality of new kinds is to grow them in pots, as then the grower can give the treatment desired. I do not advise very large kinds, as I have never been successful as regards flavour with coarse fruits, the smallest or medium sized Melons being usually the best flavoured. I do not by this remark condemn large fruits, but only give my own opinion. The best Melon I have raised (Beauty of Syon) may be termed a small kind, and some large seedlings I have not grown after the first season. If the time required for the fruits to finish and the number of fruit on the plant be taken into account, there is little gain in large fruits. Of late I have noticed that fewer large fruits are exhibited, the smaller ones nearly always being successful. G. WYTHES.

**Plum Denniston's Superb.**—I have grown this small sized dessert Plum for a good number of years both in pots and on a south-west wall, and have found it excellent in both cases. The tree crops well and regularly, ripens its fruit here in South Notts about the middle of August in ordinary summers, and hangs for some time without decaying. In fact, if left till slight shrivelling of the skin takes place, it forms a most delicious sweetmeat, and is surpassed by none for tarts and preserves. Denniston's Superb makes short-jointed, fruitful wood even in quite a young state, which cannot be said of many of even the best Plums. The fruit is oblong in shape, of a dingy yellow colour, thickly suffused with purple freckles when quite ripe.—J. C.

**Plum Early Favourite.**—At page 127 "G. W." notices this fine Plum. I quite agree with his remarks, having seen the Plum growing and fruiting well on an east wall in this neighbourhood. It is both an early and heavy cropper, and makes delicious pies and preserves. Anyone contemplating planting early Plums on a wall ought certainly to include one or two trees of Early Favourite. The old Orleans is still one of the very best of this type, rarely missing a crop, and while generally classed as a cooking Plum, is not to be despised for dessert. Where ripened on a south or west wall Orleans is a good market Plum, but it should not be planted on strong retentive soil, or gumming and premature decay are liable to follow. It would not be wise to plant it in standard form except in southern counties.—J. C., Notts.

**Pear Beurre Giffard.**—When writing of Jargonelle Pear last week I intended adding a word of praise for that most useful and good flavoured early Pear Beurré Giffard, at present, I think, but little known. In the garden under my charge it ripens simultaneously with Jargonelle, and although not perhaps quite equal to that sterling old sort is well worth growing both as regards flavour and productiveness. The fruit is of medium size, tapering towards the stalk, the colour when ripe being a mixture of yellow and

bronzy red. It is juicy and refreshing, and although, like most of the early Pears, it requires to be eaten soon after being gathered, it does not decay in the centre so soon as that well-known Pear Citron des Carmes.—J. C.

**Apple Lord Suffield.**—Where this Apple does well, no more satisfactory one, from the housewife's point of view, can be grown. On comparatively light ground on a chalk subsoil in Dorsetshire I found it flourishing grandly. Bush trees on the English Paradise stock, sixteen years from the graft, were 10 feet high and almost as much through. They looked the picture of health and were carrying a fine crop of large, smooth, clear-skinned fruit, averaging half a pound a-piece. Curiously enough, although Lord Suffield showed no signs of canker, which is so prevalent in this variety in some soils, three trees of Lord Derby in the same garden had been attacked by this disease. Standard trees of Devonshire Quarrenden were laden with a fine crop of brilliant crimson fruit. The situation of the garden was high and exposed, being but a little below an expanse of heather-clad moorland, which commanded an extensive view for many miles around.—S. W. F.

## PEACH HOUSE FACING WEST.

My Peach house is situated against a wall facing the west, and although the trees (which are the best of their kind) are very strong and healthy and flower freely, yet there is a very poor

Melon Hero of Isleworth. From a photograph sent by Mr. Wythes, Syon House Gardens.

show of fruit. Do you think the house should be removed to a wall facing the south? This is the third year only that I have had the house.—Dodo.

\* \* A west aspect for a Peach house is not nearly so suitable as would be a wall facing either south, south-west or south-east. During the first four or five years the trees are grown in a house on which the morning sun does not shine, they grow too strongly and fail to ripen their young growths sufficiently to produce fruit in quantity. The trees may flower freely and yet fail to give many fruits, owing probably to the flowers being either malformed or deficient in pollen grains. A bad attack of red spider, strangely enough, was the cause of several trees in a lean-to house facing west commencing to fruit freely, and since experiencing this severe check these trees have never failed to crop heavily. The trees being young and the border new the growth is apt to be extra vigorous, and only the spray or small weakly shoots seem capable of producing fruit under such conditions. Root-pruning is one way out of the difficulty, but even this failed in one instance that came under my notice, owing, it was thought, to the soil returned about the roots not having been made poorer. "Dodo" will do well to have his trees root-pruned, the deep running roots immediately under the stems of the trees being particularly searched for and freely shortened and rather poor loamy soil with old mortar rubbish added, packed firmly about the roots in the place of the old and perhaps richer compost. If this is done about the middle of September or while yet the leaves cling tightly to the trees, the old ball of

soil and roots given a good soaking of water and overhead syringing be resorted to, there will be little or no flagging and fresh root fibres will be formed before the leaves fall. Should the root-pruning have the effect of causing one or more trees to flag badly, then the house should be kept closer, the trees be shaded from bright sunshine, and be very frequently syringed overhead. Under this treatment there should be an improvement in the crops next season. A free use of fire-heat to a certain extent compensates for the loss of sunshine, and with the wood only moderately strong and thoroughly well matured it is just possible heavy cropping would commence without interfering with the roots. Many growers, however, have so much faith in the beneficial effects of partially or wholly lifting Peach and Nectarine trees, that they resort to the practice either annually or biennially. Early next month "Dodo" could, if so disposed, have his house shifted to a south wall and the trees be moved into it again before the ends are closed in, dragging them through narrow doorways not answering well. They ought to be carefully lifted and moved soon after the wood is firm and the buds plumped up, not waiting for the leaves to fall. If the work is properly done, a crop of fruit, though not a heavy one, should be taken from them next season. All things considered, the latter alternative would be the most certain to give the greatest satisfaction in the long run.—W. I.

**Currants at exhibitions.**—There are few fruits more difficult to judge accurately than are Currants. Whites are in small variety, and a good clean sample of the White Transparent will usually take first place if only one lot be staged. It is when there are several dishes of the same variety or, in Reds, good clean samples of Red Cherry or La Fertile, or La Versailles, as sometimes called, that it is so very difficult to determine which is best. Then cleanness or brightness helps to solve the problem, everything else being equal. When ordinary Red Dutch is shown with the Cherry, then the former invariably has to take a back place. Some smart exhibitors go over their bunches carefully and cut out the smaller or imperfect berries, thus materially improving the average sample, and if also they run them carefully through a cloth the effect is remarkable.

Currants naturally have such bright glossy skins and a certain degree of transparency, that few fruits look nicer when thus touched up. In relation to Black Currants some difference of opinion evidently prevails as to whether these should be shown in bunches or as single berries. When bunches are shown there is always great disparity in size between the upper and earliest berries and the end berries. It is commonly the case also that the large first berries are ripe fully a fortnight before the rest of the berries are. That being so, when bunches are left hanging late to finish out the first berries often drop. Now there can be no question but that it is wiser and more economical to encourage gathering of the large berries first, as by so doing there is not only less waste, but the smaller berries finish up better. For that reason some favour the showing of Black Currants in berry form and not in bunch form. For the reasons given, that is my preference also. It would be interesting to learn whether that opinion is generally held, as it is well to have equal practice at shows.—A. D.

**Rubus laciniatus.**—Planted out on the margin of a broad path in the kitchen garden at Maiden Erleigh, Reading, this excellent Bramble was the other day fruiting abundantly. No effort is made to cultivate it, as that tends too much to coarse growth, that is difficult to ripen. Summer growths of medium character that harden well in the autumn and winter carry good quantities of fruit the following season. These growths are, however, rigidly thinned. The fruit was not only very fine, but very sweet and soft, indeed delicious for the dessert. Perhaps it is because

culture tends to the production of coarse growths that complaint is sometimes made, as recently, as to deficiency of flavour in Raspberries. Very strong growths may bring the largest fruit, but it is not always the sweetest or most highly flavoured.—A. D.

## STOVE AND GREENHOUSE.

### ACHIMENES CULTURE.

CONSIDERING the attractive character of the Achimenes, it is strange it should have fallen into disrepute. A well-flowered batch of Achimenes well repays any pains and labour that may have been bestowed upon them. Formerly a class was provided for them not only at the London exhibitions, but also at local shows during May and June, and I can well remember the fine plants shown at South Kensington by Mr. Bones, of Havering Park, Romford, these being at least 3 feet across. One most important point in their management is keeping the corms in a plump condition during the winter. When the pots are laid on their sides in a very dry place, the soil sometimes becomes so hard that the corms partially shrivel and lose their vitality, starting irregularly and weakly in the spring. The best way is to fill shallow boxes with silver sand and embed the corms in it, keeping them in a dry, but cool place. The time of starting must of course be regulated by the date at which the plants are wanted to flower. If in May they must be placed in heat in January; if in June, February and so on, March pottings securing a batch in July. Some growers put the corms into the pots or pans in which they are to flower at first, planting rather thickly and thinning out when an inch high. Others prefer to sow in boxes or pans and to transplant when an inch high, and doubtless both ways have their advantages. Whether pots or pans are employed, good drainage is needed, as anything approaching stagnation at the roots is fatal to Achimenes, and they, moreover, take copious supplies of water when well established. Some growers pass the soil through a rather fine sieve, but this I do not approve of, as Achimenes enjoy an open porous root run, such being likewise less liable to become compressed and sour. I prefer soil of a light loamy nature, a fourth part leaf mould, dried cow manure and silver sand being added. Early batches may be grown in an ordinary stove if given a light position and shaded from the full glare of the sun, but I have found an intermediate heat suit them best, this furnishing a more stocky and branching habit of growth. Achimenes are soon crippled by draught, and for this reason ought not to be subjected to front air till June. Many a healthy lot of plants has been entirely ruined by the sun shining fully on the foliage in March or April while yet wet from the morning's syringing; hence the necessity of a permanent shade. A piece of tiffany or thin canvas tacked over the roof glass is the best preventive. Early closing coupled with plenty of atmospheric moisture is essential to a free and rapid growth, and if wanted for exhibition the young plants must be pinched when 4 inches or 5 inches high. For the latter purpose large shallow pans are most suitable, but for ordinary decorative purposes 6-inch pots will be found to answer best. When rooting freely, weak liquid manure made by steeping a bag of sheep manure in a tub of water may be given with benefit three times weekly, and where show specimens are wanted, training should commence as soon as the shoots are pliable enough, nothing answering better for supports than small Hazel canes. When the bloom shows itself a somewhat cooler temperature is advisable, as flagging and bloom-dropping will follow any sudden removal from a stove to an airy conservatory or exhibition tent. For later batches cooler treatment answers well enough, and the plants may be placed in a north house to retard them if great care is used in watering.

The freest growing and most profuse blooming kinds are Ambroise Verschaffelt, Sir Treherne Thomas, Mauve Queen, longiflora alba, grandiflora and Dazzle. J. C.

**Tuberose for late work.**—Where these are grown specially for late or midwinter work, they are best potted at the end of May or early in June. To defer the potting later than this will not only materially affect the number of flowers on any one spike, but I believe it also accelerates blindness. As Tuberose in midwinter are by no means too plentiful, particularly after the end of November, endeavour should be made to pot the bulbs at the right time. After the potting is completed, the bulbs are best plunged in the open in cocoa fibre or ashes. Here the growth will be very slow from the first. By the middle of August, however, some of the forwardest will be pushing forth spikes, and at this stage they will need slight protection at night. Where the spikes are not as yet appearing the plants will be quite safe for a week or two longer. So far as my experience goes, I have found it best to get the spikes fully 6 inches above the pot by the first week of September, as there is more likelihood of these coming away well. They are also stronger than those spikes which come late in the autumn. The use of small sized pots for these late batches is one of the best aids to the flowering of the Tuberose. Red spider and thrips are very troublesome at times, but if the plants are frequently syringed, these may be in a measure checked. While still in the frames I am rather partial to overhead watering with either soot water or liquid manure. Soot water may also be freely used for syringing till the flowers begin to expand. This and quassia water, with a moist atmosphere, will do much to keep red spider and thrips in check.—E. J.

**Ixora Colei.**—This, which is said to be a hybrid between *I. coccinea* and *I. stricta* alba, stands out conspicuously among the many *Ixoras* grown in our gardens from the fact that while in nearly the whole of them the blossoms are of different shades of orange and salmon, those of *I. Colei* are pure white. It is of good habit, well furnished with deep green foliage, while the flowers are freely borne, and as a rule a succession is kept up for some time. As a pretty free-blooming stove shrub this *Ixora* certainly merits a passing notice.—H. P.

**Pot Mignonette.**—About the third week in August is a very good time to make a sowing of Mignonette in pots for a supply of bloom during February and March, the second or third week in September being soon enough for a batch to flower in April. I use 6-inch pots, draining thoroughly, employing a compost composed of good friable loam, not sifted, but pulled to pieces with the hands, a little leaf-mould and road grit being added. Some advise manure, but I think this is apt to induce a sappiness in the early stages of growth, which renders the plant liable to die off through damp during November and December. If weak manure water is given in January the seedlings soon strengthen, and patchy plants are then the exception. After filling the pots to the required height the soil is made level with the base of a small pot and the seed sown thinly. Thick sowing should be avoided, as in thinning out the plants where crowded those that are to remain are much loosened, which is an evil. The seed should just be covered with fine soil and the surface again made firm, the pots being then placed in a frame on a hard bed of ashes. It is a good plan to turn the frame towards the north, as then the soil does not get so dry and shading is unnecessary. Tilt up the lights until the young plants appear, after which the frame may be turned round and the lights removed by day, placing them on at night and tilting up. As the plants strengthen, entire exposure both by day and night is best until the approach of frost necessitates the removal of the plants under glass. Repeated rains, however, being injurious, protection must be given in very wet weather. Seven or eight plants are sufficient for each pot;

when more are left side growths are poor and the bloom trusses weakly. I usually keep my plants in the frame until the middle of November, then give them a position near the glass in a cool, airy house. Liquid made from either cow or sheep manure suits Mignonette well, giving it three times a week of moderate strength only at the beginning of the new year. In regard to varieties I find none so suitable for pot work as Miles' Spiral. Machet is a good sort, but not in my opinion equal to Miles' Spiral.—J. C.

**Panax longissima.**—This is a New Zealand tree of peculiarly striking habit and one of the most effective of cool greenhouse fine foliaged plants. It is not, however, very plentiful even in its native country, and is consequently not often seen in our conservatories. In the temperate house at Kew there are several specimens whose handsome leaves contrast well with the ordinary types of foliage amongst which they are growing. The largest plant is about 12 feet high and has three erect stems, the surface of these stems being remarkably ridged and corrugated. The stiff, sword-shaped leaves, from 1½ feet to 3 feet long, but scarcely more than 1 inch wide, are of a very dark green, relieved by the yellow midrib, the margins being very sparsely toothed. The leaves are perfectly rigid and point downwards, so that the points stand away only a few inches from the erect stem. The plants are of extremely slow growth. *Panax* is nearly allied to *Aralia* and the plants do not flower until of large size. Several of the species change the character of their foliage as they reach the adult state, the simple leaves, of somewhat the same character as those described above, being replaced by others of more or less digitate or palmate shape.

**Erythrina Humel.**—At this season of the year especially the brilliant scarlet flowers of this *Erythrina* are very acceptable in the cool house. This year it is flowering exceptionally well, the bright sunshine of the early part of the summer having evidently suited it, as might indeed be expected in the case of a native of South Africa. Like all the *Erythrinas*, the leaves of this are trifoliate, the leaflets being of rhomboid outline with spiny petioles. The flowers are densely clustered at the upper third of a tall raceme, which stands clear above the foliage from 12 inches to 18 inches. The habit of the plant does not conform to that type, which is commonly known as good, for it has a bare rugged stem and the leaves are confined to the ends of the branches. It is useful, however, for associating with other plants of more bushy spreading growth. An older name for it is *E. caifra*, under which it was figured many years ago in the *Botanical Magazine*, t. 2431.

### SPECIES OF ÆSCHYANTHUS.

DURING the latter part of the summer and often well on into the autumn the bright blossoms of several species of *Æschynanthus* form a very prominent feature in the stove, yet, though they readily lend themselves to different modes of culture, their merits are frequently not sufficiently recognised. There are several species in cultivation, and in some cases they are a good deal alike in general features; hence where space is limited two or three distinct forms are all that are needed. In selecting three I should be inclined to name two old forms, viz., *Æ. grandiflorus* and *Æ. Lobbianus*, and the charming little *Æ. Hildebrandi*, which has for a couple of seasons at least formed such a brilliant feature at Kew, where it flowers much earlier in the year than the other kinds. Of these *Æ. grandiflorus* is more compact in growth than several of the others, and forms quite a bushy plant from 18 inches to 2 feet in height, clothed with oblong lanceolate leaves 3 inches or nearly so in length and of a deep green tint. The blossoms, which are borne in large clusters on the point of every shoot, are peculiarly curved and of a bright orange-scarlet colour. *Æ. Lobbianus* is far more of a trailer than this last, and the long slender branches are clothed in a regular manner with small deep green leaves, while the

flowers, which spring from a dark purple cup-shaped calyx, are of a rich bright red, quite distinct from the preceding. *E. Hildebrandi*, when but 3 inches or 4 inches high, flowers so freely that its brilliant orange-scarlet coloured blossoms form quite a compact mass. I have not seen this charming species other than at Kew, and it does not occur in any nurseryman's catalogue that I have perused.

The culture of the various species of *Eschynanthus* is not at all difficult, and they readily adapt themselves to various modes of treatment. In the first place they may be grown in pots in the orthodox manner if the pots are well drained and the soil used is principally fibrous peat, with a good sprinkling of sharp sand and some live Sphagnum mixed with it. Next they may be grown in suspended baskets, and this is perhaps the best way to show their beauty. *E. Lobbianus* is particularly adapted for this mode of cultivation, as the long pendulous shoots, clothed in a very regular manner with their dark green leaves, form a very pleasing object at all seasons, and from August onwards for two or three months its beauty is greatly enhanced by the clusters of brightly coloured blossoms. A third method, by means of which very effective specimens can be obtained, is to take a piece of dead Tree Fern stem and set it in the centre of a pot, the *Eschynanthus* being planted in the soil with which the base of the Fern stem is surrounded to keep it in position. Now, if the shoots as they grow are secured to the stem by a few pegs and a little live Sphagnum Moss to maintain a certain degree of moisture, they quickly attach themselves to the stem by roots produced from various parts of the branches, with the result that in time they form a dense mass, and grown in this way they are when in flower very effective. All the species will succeed with liberal supplies of water during the growing season, but at the same time it should be borne in mind that they are naturally epiphytes, hence ample drainage must in every case be ensured, as the roots, which are not particularly numerous, are very impatient of stagnant moisture. H. P.

***Pteroma macranthum floribundum*.**—The typical form of *Pteroma macranthum* was introduced in the early sixties, and for the last twenty years has been a fairly well-known plant. For flowering in a rather warm greenhouse (what is known as intermediate) there is no plant that makes a more effective display during the latter half of the year. Even in a cool greenhouse or winter garden it thrives well enough to be always worth a place, although the flowers are not so large, neither is the foliage so vigorous and handsome as when treated to a little more heat. The leaves are from 4 inches to 6 inches long, ovate in outline, the surface rugose and downy, and traversed by the three prominent veins running lengthwise, that are so constant a feature in the Melastomads. In this note I desire more particularly to draw attention to the variety known as *floribundum*. The flowers of the ordinary *P. macranthum* are each 3 inches to 4 inches across, but in the variety just mentioned they are, as a rule, close upon 6 inches in diameter, and occasionally 7 inches. This enormous width of flower is accompanied by such breadth and substance in the petals that there is no space between them, and they give to the flower a fulness which, combined with the brilliant blue-purple colour, makes the individual blossom the showiest perhaps of all stove and greenhouse plants.—B.

***Dianella aspera*.**—The *Dianellas* are a group of greenhouse plants noted for the beauty of their fruits belonging to the Lily family, and natives of New Zealand, Tasmania, and Australia. Several of them are of extremely graceful habit, having slender stems and long arching leaves, providing a type of foliage which might well be more abundantly represented in our conservatories and winter gardens than is now the rule. *D. aspera* is a species of a somewhat stiffer habit than most of the others, but, considered from the point

of beauty in the fruit, is the handsomest of all. The fruit, about the size of a large pea, is produced abundantly in panicles 1 foot or more long, and ripens during the month of August and becomes a beautiful bright blue. A plant in the temperate house at Kew about 4 feet high is now well furnished with panicles of fruit. The flowers of this and other *Dianellas* are also very pretty, being of small size, but borne numerous on light graceful panicles, and varying from white to light and deep shades of blue. *D. cœrulea*, *tasmanica*, and *lævis* are all well worth cultivation, and although rare, are still to be found in some gardens.

#### HYMENOCALLIS (ISMENE) AMANCAES.

**HYMENOCALLIS AMANCAES**, the so-called Peruvian Daffodil, the celebrated *Amancaes* of the Peruvians, in honour of which the natives yearly hold a kind of religious ceremony, was first brought into cultivation as long ago as 1804. There exists a figure of it in the "Flora Peruviana" of Ruiz and Pavon, together with a cut

*Hymenocallis (Ismene) Amancaes.* Engraved for THE GARDEN from a photograph sent by C. G. Van Tubergen, Jun.

of *Elisena longipetala* (see note in THE GARDEN, August 1, 1891). We find stated that at the time of its introduction it was considered to be a hothouse plant, and was treated accordingly.

Dean Herbert, however, who has done so much to increase our knowledge of bulbous plants, of *Amaryllideæ* in particular, soon found that after giving the bulbs a period of absolute rest during winter he could induce them to flower out of doors. He therefore planted the bulbs in spring on a very sunny border, or against a wall looking south, where the flowers were produced in June.

The present engraving, which was made from a photograph of a plant grown by me in that way, gives a good idea of the flowers. These, numbering from four to seven, or even more, according to the size of the bulbs, are borne on a stout stem nearly 1 foot in height. They are of the deepest yellow, and have both inside and outside six bright green broad bands running down the widely-expanded, Daffodil-like cup.

The blossoms exhale a very strong, powerful fragrance, noticeable at a fair distance. When cut off and put into water, they remain fresh nearly a week. C. G. VAN TUBERGEN, JUN.

*Haarlem, Holland.*

***Rhododendron retusum*.**—This is one of the few species that have been introduced from the region of the Malay Archipelago, a section of the genus, which, in spite of its small numbers, has, in the hands of the hybridiser, given birth to the fine race of greenhouse *Rhododendrons*, now so well known by the exhibits of Messrs. Veitch. *R. retusum* is not one of the finest of the Malayan group, but it is a rare plant, and it is interesting to see it flowering in the large temperate house at Kew. The specific name refers to the shape of the leaf, which is  $1\frac{1}{2}$  inches to  $2\frac{1}{2}$  inches long, obovate, and retuse (or even emarginate) at the apex. It is also of a dark glossy green, paler and minutely dotted beneath. The flowers, in clusters of half a dozen or more, are pendulous. The corolla is 1 inch to  $1\frac{1}{2}$  inches long, bright red, tubular, with

five slightly spreading rounded lobes. The species is a native of the mountains of Java, and was introduced in 1853.

#### SHORT NOTES.—STOVE & GREENHOUSE.

**Ivy-leaf Pelargonium Rycroft Surprise** is in its way a very fine variety. It produces large bold trusses of dark salmon-pink flowers the whole summer. The habit of the plant is dwarf and branching, unlike most of the sorts; this renders it valuable for pot culture.—H.

***Lilium Kretzeri*.**—When the value of this fine white Lily for pot work is better known, it will, I am sure, be more often grown. For producing large plants, by placing five or six bulbs in a 12-inch pot, it is unsurpassed, growth being both tall and branching. For placing in the windows of front halls, or for mixing with groups for indoor decoration, it is invaluable, and all who need autumn flowering Lilies for such purposes should grow it.—J. C.

## SOCIETIES AND EXHIBITIONS.

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 27.

THE meeting on Tuesday was a full and representative one for August, outdoor flowers being the chief feature, especially Gladioli and Asters, which made a solid bank of colour the entire length of the hall. Orchids, though less in number, were represented by some choice new hybrids, whilst Mr. Woodall's grandly flowered plant of *Vanda cœrulea* was a centre of attraction. Fruit was largely shown, particularly Apples and Plums.

## Orchid Committee.

First class certificates were given to—

*CATLEYA AUREA* MRS. FRED HARDY, which differs from the type in having pure white sepals and petals; lip similar to that of a fine variety of *C. Dowiana aurea*. From Messrs. F. Sander and Co.

Awards of merit were given to—

*CÆLYGNE VEITCHI*, a new species, with small pure white flowers borne on pendulous spikes. It belongs to the same section as *C. Dayana* and *C. Massangeana*. From Messrs. J. Veitch and Sons.

*LÆLIO-CATLEYA ELEGANS OWENLE*.—An extra fine variety of the Turneri section, with a pure white throat. Unfortunately, the flowers were not fully expanded. From Mr. Statter.

*LÆLIO-CATLEYA CHARLES DARWIN*.—A hybrid between *L.-C. elegans Turneri* and *Cattleya maxima*; sepals and petals crimson-purple, lip deep crimson in front and through the centre to the throat. The sides of the throat are bright orange yellow at the base, the upper part rose, tipped with crimson. From Mr. C. Ingram.

*DENDROBIUM HOOKERIANUM*, better known as *D. chrysoctis*, under which name it had previously received a first-class certificate. Sepals and petals bright yellow, lip yellow, heavily fringed in front, with two chocolate-brown discs in the centre. From Sir T. Lawrence.

Mr. T. Statter sent a very fine collection of cut flowers, principally *Cattleyas* and *Lælias*. Prominent amongst these were *L.-C. elegans* var. *excellens*, *L.-C. elegans* var. *prasiata*, *L.-C. elegans Cheloniensis*, *L.-C. callistoglossa*, *L.-C. Nysa*, two fine varieties of *Cattleya Rex*, a fine spike of *C. Gaskelliana* var. *alba*, two forms of *C. guttata*, *Cypripedium memoria Mœnsi*, *C. lancifolium* and *Dendrobium Phalenopsis* in variety. A silver Flora medal was awarded. Messrs. J. Veitch and Sons were also awarded a silver Flora medal for a small, but interesting group, consisting of two fine varieties of *Cattleya Dowiana aurea*, *Vanda Sanderiana*, two plants of *Cattleya Eldorado alba*, *Cypripedium warnhamense*, *C. tonsum superbum*, some fine varieties of *C. Curtisii*, *C. Charlesworthii* (with an immense dorsal sepal), *C. cœnanthum superbum*, *C. Chas. Canham* and a fine plant of *Miltonia vexillaria superba*. Messrs. F. Sander and Co. sent a fine group, amongst them being *Cattleya Fowleriana* (shown at the last meeting), *C. aurea Statteriana*, *Habenaria carnea*, *Miltonia vexillaria*, *Burlingtonia pubescens*, *Oncidium Forbesi*, *Dendrobium Phalenopsis Schrederianum* in variety, *Pleurothallis bracteata*, *Cypripedium cœnanthum superbum*, and some fine plants of *Oncidium Jonesianum* and *Angraecum Scottianum* (silver Banksian medal). Mr. F. Hardy exhibited *Lælio-Cattleya elegans Turneri*, *L.-C. x Hardyana* (said to be the reverse cross of *L.-C. callistoglossa*), and a fine variety of *Oncidium Kramerianum*. Mr. C. Ingram sent *Lælio-Cattleya elegans Turneri elsteadensis*, *L.-C. e. Ingram's* var., and *L.-C. Elstead Gem*, described in the report of the last meeting. The plant now shown was considered superior to the one shown at the previous meeting, being much brighter in colour.

Sir T. Lawrence sent an exceedingly large-flowered var. of *Catasetum Bungeorothi*, *Stauroopsis philippinensis*, *Oncidium Lanceanum*, and *O. hamatochilum*. Mr. A. H. Smee sent *Aeranthos*

*grandifolium* and *Catasetum* species. Mr. De B. Crawshay sent a well-grown plant of *Odontoglossum Uro-Skinneri*. Mr. E. H. Woodall sent a finely grown plant of *Vanda cœrulea* with seven spikes of flowers, *Cypripedium Morganæ* with three spikes, *C. Stonei*, and *Odontoglossum coronarium*. Mr. F. W. Moore, Glasnevin, showed *Oncidium St. Legerianum* and *Bulbophyllum Reinwardti*. Messrs. Lewis and Co., Southgate, sent a group, consisting of the rare *Cypripedium Enever* (a hybrid raised from *C. concolor* and *C. Argus*), *C. Charlesworthii*, *C. radiosum*, *Miltonia Moreliana*, *M. spectabilis virginialis*, *Cypripedium Godefroyæ* with a white ground, *Dendrobium erucum*, a fine variety of *Cattleya Warszewiczii*, *Habenaria Susannæ*, *Odontoglossum grande*, and *Oncidium olivaceum Lawrenceanum*. Messrs. Hugh Low and Co. had two fine plants among their small group of the Swan Orchid (*Cycnoches chlorochilon*), showing the male and female flowers, several fine varieties of *Cypripedium Charlesworthii*, *Dendrobium Phalenopsis*, *D. speciosissimum*, a fine variety of *Odontoglossum Harryanum*, and *Bulbophyllum Huttoni*. Messrs. B. S. Williams sent *Pachystoma Thompsoni* and *Odontoglossum Kramerianum*.

## Floral Committee.

Awards of merit were granted to the following:—

*ALOCASIA LOWI GRANDIS*.—This is quite distinct from *A. Lowi*, having broader leaves of a very deep olive-green colour, with the white leaf veins also much more prominent. It is a beautiful fine-foliaged plant, and was shown by Messrs. Hugh Low and Co.

*ROBINIA NEO-MEXICANA*.—A new and beautiful *Acacia*, which bears abundantly dense clusters of flowers of a rosy pink colour, resembling those of the *Rose Acacia*, but produced in long succession upon the growing shoots. It will make a large tree, but flowers freely in a young state. From Messrs. Paul and Son.

*KNIPHOFIA PEITZERI*.—This is a very fine variety, with large dense heads of great length and extra brilliant in colour. Shown by Mr. M. Prichard, Christchurch, Hants.

*SCABIOSA CAUCASICA ALBA*.—The pure white form of the Caucasian *Scabious* is now well known, and is equally as fine a garden flower as its blue parent. This also came from Mr. Prichard.

*GLADIOLUS KATE ROSE*.—A pretty variety, with large flowers, which are of a French-white colour, slightly feathered with light mauve-purple. Shown by Messrs. Kelway, of Langport.

*GLADIOLUS DOLOPS*.—This bright and handsome kind has a bold spike and large flowers of rich salmon-red colour. From Messrs. Kelway.

*GLADIOLUS BRANTFORD*.—A distinct and striking self-coloured variety of a deep dark crimson hue, overlying scarlet, this latter tint more prominent in the throat. Also from Messrs. Kelway.

*DAHLIA (POMPON) FABIO*.—This pretty kind has flowers of a rich glowing crimson at the tips of the florets, this colour shading gradually to deep orange at the base. It was shown by Messrs. Charles Turner and Son, Slough.

*DAHLIA (POMPON) PURITY*.—The flowers of this are pure white, neat and well formed, but apparently no improvement on existing kinds. From Messrs. Turner.

*DAHLIA (POMPON) NERISSA*.—A distinct kind with self-coloured flowers of a bright rosy lilac tint. From Messrs. Turner.

*DAHLIA (POMPON) DOUGLAS*.—The flowers of this kind are of an intense dark crimson shade, almost black at the tips of the florets. From Messrs. Turner.

*DAHLIA (CACTUS) BEATRICE*.—This has flowers of true Cactus form and in colour a distinct shade of light mauve-purple. From Messrs. Turner.

*DAHLIA (CACTUS) LEONORA*.—A large-flowered and handsome kind, rose or magenta-red, shading to mauve at the tips of the long pointed florets. From Messrs. Turner.

*DAHLIA (SHOW) DANTE*.—This, one of the big flowered show varieties, has a full solid bloom of

a dark maroon-crimson colour. From Messrs. Turner.

*DAHLIA (SHOW) MABEL STANTON*.—A yellow kind of large size, rich in colour and of perfect show form. Also from Messrs. Turner.

Messrs. Kelway, of Langport, made a most noteworthy display of all their best Gladioli, showing about sixteen dozen grand spikes, of which the best, in addition to those previously mentioned, were *Marsi salmon*; *Helotes*, crimson with a white throat; *Ollins*, deep crimson self; *Onabus*, rosy cerise; and *Gildo*, lilac-rose, shading to a lighter tint, with yellow blotch in the throat. A silver-gilt Flora medal was deservedly awarded. Asters from Messrs. J. Veitch and Sons were a large and comprehensive collection of the many strains and types now existing in this fine autumn annual flower. A silver Flora medal was awarded. Messrs. Dobbie and Co. also showed a fine lot of this flower grown at their Orpington seed grounds. The giant white Comet Aster was very beautiful in this group, its flowers as informal and graceful as those of *Lady Selborne Chrysanthemum*. A silver Banksian medal was granted. Messrs. Barr and Son received a silver Flora medal for a large and characteristic group of the best hardy flowers of the season. Perennial Sunflowers were represented by the best kinds, and *Rudbeckia Autumn Glory* is a hardy flower all should have, although it is unfortunate that this fine flower should have two specific names and a popular one besides. *Tritoma Saundersi*, an old, but by no means to be despised variety; *Gladiolus Saundersi*, a free and pretty species, with early Asters, fine Phloxes, and Tiger Lilies were also noteworthy in this group. Mr. M. Prichard also showed hardy flowers admirably, many choice and lovely things figuring in his group. *Lilium tigrinum splendens* was shown here very fine indeed, also *Kniphofia Macowani*, an old, but free-blooming, very hardy variety. *K. Phœbus*, one of Max Leichtlin's raising, is a distinct Torch Lily, with a thick spike of yellow flowers, and *K. Lachesis*, from the same raiser, is very pretty, with a crowded spike of orange-yellow flowers that have long exerted anthers. *Montbretia rosea*, *Eupatorium purpureum*, *Helianthus Miss Mellish*, *Lobelia fulgens* Robert Parker, *Hemerocallis Middendorffiana*, and *Trollius Orange Globe* were all noteworthy in this group, which received a silver Banksian medal.

A varied group of hardy flowers and flowering trees and shrubs shown by Messrs. Paul and Son was awarded a silver Flora medal. Phloxes were fine here, notably the varieties *Eclatante*, *Auguste Riviere*, *Purity*, *Esna*, and *Iris*. *Lobelia syphilitica robusta*, with long spikes of clear blue flowers, was handsome. *Helianthus rigidus* Miss Mellish was represented by a noble bunch of large flowers. The perpetual-flowering *Acacia* was shown, and the new rosy-flowered Mexican variety, also many wild *Roses* in fruit, and *Crassula rubicunda*, a bright-coloured, succulent plant with red-tipped leaves and crimson flowers, a striking plant as shown, filling a large pan. Mr. Cannell showed a quantity of the old *Cockscomb* in many shades of colour, but none of them striking enough to increase interest in this floral monstrosity, whilst the great ugly double Sunflower shown in this group we hope will not often be seen in gardens. Some very good double *Begonias* were included in this group, the plants dwarf and carrying their flowers erect, and *Cannas* were very fine, the plants having one stem only and in small pots, but bearing large clusters of flowers. A silver Flora medal was awarded, and a similar award went to Mr. J. F. McLeod, gardener to Mr. Morgan, Dover House, Roehampton, for a representative group of *Crotons*, which comprised all the finest varieties in well-grown, highly-coloured plants of a useful decorative size. A group of *Lilium auratum platyphyllum* and *L. a. rubro-vittatum* with Dahlias from Mr. T. S. Ware received a bronze Flora medal, and Mr. J. Ouvrard, Child's Hill, Kilburn, was awarded a bronze Banksian medal for a group of *Phrynum variegatum* and *Maranta major*, the latter a new form and a useful decorative stove plant, with

broad, short, deep green leaves borne on erect stems about 2 feet high. A charming lot of *Saxifraga sarmentosa* tricolor was sent from the society's garden at Chiswick, and seedling *Gladioli* came from Mr. Thomson, of Cardiff. Hybrid *Fuchsias* were shown by Mr. P. Fry, West Malling, and two enormous *Pampas Grass* plumes came from Messrs. Osman, but they looked as though they had derived some of their size from clever manipulation.

#### Fruit Committee.

Awards of merit were given to the following:—

**APPLE WILLIAMS' FAVOURITE.**—This is said to be a good dessert kind. The fruits are large, conical, with an eye of medium depth and a shallow cavity at the base, with an unusually thick footstalk. The colour is very attractive, being deep red all over. It was shown by Mr. G. Bunyard.

**APPLE (CRAB) JOHN DOWNIE.**—One of the ornamental Crabs that have been often praised in these pages. Long branches were shown laden with conical Plum-like fruits of a bright red and yellow colour. This also came from Mr. Bunyard.

**APPLE (CRAB) TRANSCENDANT.**—Another free-fruited, distinct and showy kind to plant for ornament. Its fruits are larger than those of John Downie, but quite as freely produced and equally brilliant in colour. It was shown by Messrs. J. Veitch and Sons.

Messrs. Veitch and Sons showed an excellent collection of Apples (thirty dishes), Pears (ten dishes), Plums (forty dishes) and Peaches (seven dishes) grown at the Southfields and Langley nurseries. The best Apples were Lord Suffield, Potts' Seedling, Nonsuch, Lord Grosvenor, Warner's King, Stirling Castle, Grenadier, New Hawthornden, Duchess of Oldenburg, Duchess Favourite, Worcester Pearmain and Lady Sudeley. The best Pears were Fondante de Cuerne, Triomphe de Vienne, Colmar d'Été, Clapp's Favourite, Bacon and Williams' Bon Chrétien. Among the Plums, Cox's Emperor, Transparent Gage, Monarch, Royal Hâtive, Jefferson, Archduke, Yellow Magnum Bonum, Pond's Seedling, Dymond, Lawson's Golden Gage and Standard of England were the best. The best Peaches from trees in pots were Comtesse de Montigo, Barrington, Conkling, Violette Hâtive, and Dymond. They also sent branches of Siberian, Transcendant and Transparent Crabs, Superlative Raspberry and Blackberries (silver-gilt Knightian medal). From the Royal Gardens, Frogmore, Mr. Owen Thomas sent thirty-eight dishes of Plums, Belle de Septembre, Victoria, Washington, Archduke, Transparent Gage, Sultan, Coe's Golden Drop, Pond's Seedling, Kirke's and Standard of England being the best (silver Knightian medal). Messrs. Spooner and Sons, Hounslow, staged a fine collection of Apples (forty-five dishes) and seven dishes of Plums, the best Apples being Pott's Seedling, New Hawthornden, Grenadier, Lord Grosvenor, Schoolmaster, Stirling Castle, Ecklinville, Worcester Pearmain, Bismarck and Frogmore Prolific. The best Plums were Sultan, Victoria, Black Diamond, Pond's Seedling, and Monarch (silver Banksian medal). Seedling Melons came from Mr. Wythes, Syon Gardens; Mr. R. Doe, gardener to Earl Derby, Knowsley, Prescott; Mr. John Miller, gardener to Lord Foley, Ruxley Lodge; and Mr. W. Batchelor, Harefield Road, Harefield, but no awards were given. Mr. T. W. Eames, Twickenham, and Mr. Owen Thomas, Frogmore, sent new Cucumbers. Mr. Hooking, Almondsbury, sent Hooking's Prolific Kidney Bean. Mr. R. Davis, Edmonscote House, Castle Hill, sent a Tomato named Edmonscote Favourite. From Mr. W. Potten, Camden Nurseries, came a box of *Malus baccata*. Mr. J. Garland, Killerton, Exeter, sent a seedling Peach. Messrs. Cannel and Sons, Swanley, sent two dishes of Tomato The King, and Mr. W. Rapley exhibited a good dish of Sutton's Perfection Tomato grown outside. Mr. A. Bishop, Westley Hall, Bury St. Edmunds, sent a seedling Nectarine. Mr. John Miller, Ruxley Lodge, exhibited a small collection of fruit, including good

Brown Turkey Figs and Hemskirk Apricots. From Mr. G. Wythes, Syon Gardens, came a new dwarf Bean, named Syon House Prolific, the pods very large and freely produced.

The fruit committee met at Chiswick on August 16 to examine the Tomatoes grown in pots, also Runner Beans, Cabbages, and other crops. Of Tomatoes very few new kinds showing special merit were noted. The following had previous awards confirmed: Comet, good-sized, smooth, scarlet fruit; Tennis Ball, small, round, scarlet, good for dessert; Sutton's Dessert, scarlet, very free and good; Golden Princess, deep, round, handsome rich yellow fruits. Three marks were awarded to Sutton's Early July, of medium size and very early; also Cherry, a small Cherry-shaped fruit of rich flavour. The following Runner Beans had three marks awarded: Sutton's Prize-winner, a superior long-podded form; Sutton's A I, also a fine variety; Leviathan, a first-rate cropper; and Capp's White, very prolific, the best of that section. Of smooth-podded varieties, the only forms worthy of notice were Sutton's Tender and True and Veitch's Climbing French Beans, which were considered by the committee to be identical. The best dwarf stocks of Cabbage were those of the Improved Nonpareil sent by Messrs. Veitch and Sons and Nutting and Sons; the best second earlies, Earliest (Sutton and Sons), Best of All (Barr and Son), Express and Etampes (Vilmorin et Cie). All of these were considered to be of the same stock.

The lecture on *Crotons* and *Dracenas* was, in the absence of Mr. Bause, read by Mr. G. Bunyard.

#### NATIONAL CO-OPERATIVE FLOWER SHOW.

AUGUST 23, 24.

The tenth annual show of the National Co-operative Society was held as usual at the Crystal Palace, and, having regard to its annual increase in extent, this place has become absolutely essential in order to furnish room for such a mass of exhibits. The entries were in excess of those on any previous occasion, although the extent of the show appeared smaller. This, however, was owing to one half of the central transept being occupied with some permanent exhibits that form part of this season's attractions at the Palace, and consequently the flower show exhibits were unavoidably crowded together. The exhibition is divided into two sections and several sub-divisions, embracing sectional areas of the country, a wise proceeding that enables exhibitors to compete under something approaching equal conditions. The cut-flower classes and those for plants in pots showed a very marked increase on previous years, as there were over 1200 entries of cut flowers and more than 500 of plants in pots besides some table decorations, altogether making the flower classes numerically nearly as strong as those for vegetables, of which there were 1823 entries. Those who have watched the progress of this annual fixture must have marked the gradual advance, not merely in point of numbers, but in the high quality of the cottagers' exhibits, a great number of which will bear favourable comparison with the productions of experienced gardeners.

#### VEGETABLES.

These, it is almost needless to say, are the leading feature in the first section of the show, that embraces cottagers and allotment-holders mainly, and the collections make a prominent display, the country being divided into seven sections of adjacent counties in the respective districts, whilst collections were forthcoming from each. The southern division of England is sub-divided into two areas, and the prize collections from Mr. G. North, of Banbury, and Mr. W. Byles, of Wilton, were exceedingly good. Mr. Maylott, of Hereford, in the western division, and Mr. Luff, Bromley, from the metropolitan district, also showed well, whilst fair collections that secured first honours in their classes came from Lough-

borough and Sawley. The single classes for various vegetables brought out some very keen competition, the Runner Beans being most noteworthy. French Beans were equally well shown. There were over sixty entries in the class for Carrots. Beetroot, both long and Turnip-rooted, was a large class, but the very common error of sowing too soon was manifest here, and many of the samples shown were much too large and coarse. The Potato classes were well filled and some excellent tubers shown, although here and there a tendency towards coarseness was apparent. Leeks, Onions, Parsnips, Cabbages, Cucumbers, and Turnips were all largely shown. In the section for gentlemen's gardeners many fine exhibits were forthcoming, Mr. Wright, of Glewston Court Gardens, securing first prize for an admirable and well-staged collection of vegetables. In another class Mr. C. J. Waite secured premier honours. Here, again, the Oxford growers were very prominent. Honours were about equally divided in the Potato classes between Messrs. Waite, Holton, Hawkins (who also comes from Oxford) and Chamberlain.

#### FRUIT.

A very fair lot of fruit was shown in the gardeners' and amateurs' section, where Mr. Nowell, of Hereford, was very successful. He was first for a collection of fruit, showing very fine Black Hamburg and Mrs. Pearson Grapes, Barrington Peaches, Souvenir du Congres Pears and Brown Turkey Figs. The same exhibitor was first for a collection of open air fruit. Cooking and dessert Apples were largely shown, there being about sixty dishes in each class, but the Kent growers held their own here, securing the chief prizes.

#### FLOWERS.

These hitherto have been chiefly shown by those who reside in the metropolitan district, but we noted with satisfaction many excellent flower exhibits from cottagers in the provinces. Pot plants alone would have made a large display, only they had to be crowded down the centre of the already overloaded tables. There were many really good examples showing what amateurs can accomplish, and in addition to the conventional sorts of pot flowers, such as *Fuchsias* and *Geraniums*, *Begonias* and *Petunias*, many annuals in pots, such as *Asters*, *Phlox Drummondii*, *Lobelias*, *Tropæolums*, and *Balsams*, well grown and flowered, were shown. The cut flowers in the cottagers' classes were chiefly annuals, but fresh and fine. The stand of a dozen African Marigolds with which Mr. Ward, of Horsham, secured first prize in a strong class was a really excellent one. *Zinnias*, *Mignonette*, and *Everlasting Flowers* were all largely shown, also *Dahlias* of great merit, whilst the basket and stand of *Roses* from Mr. Green, of Oxford, must not be omitted, as good blooms of several *Tea Roses* were present. Flowers were also a prominent feature in the gardeners' and amateurs' section, including pot plants and cut flowers. Annuals in great variety predominated here. *Dahlias* were abundant, Mr. Hudson, of Gunnersbury, showing, not for competition, single and double Cactus-flowered kinds in quantity, and a class for hardy flowers in bunches brought out some admirable exhibits, Mr. Waite obtaining the first place. Floral arrangements showed a little advance in the desired direction of lightness and grace, but the plan of packing the flowers together into a very solid bunch was still largely manifest.

**National Chrysanthemum Society.**—A meeting of the general committee was held at Anderton's Hotel on Monday last, when Mr. Wynne occupied the chair. The secretary announced that the annual outing of the members was held on July 23, upon which occasion the testimonial—consisting of a silver inkstand and an illuminated address—was presented to Mr. R. Ballantine on the occasion of his retirement as chairman of the general committee. Upon the motion of Mr. Williams, it was resolved that the committee place on record an expression of sorrow

at the death of Mr. Arthur Wortley, one of the oldest members of the society and formerly secretary of the old Stoke Newington Chrysanthemum Society as far back as 1851. In consequence of the resignation of Mr. W. E. Beyce and Mr. J. Newton from the general committee, Mr. George Walker and Mr. Wm. Holmes were elected to fill the vacancies. Some time was devoted to the consideration of details relating to the society's jubilee next year, and a special committee was elected to give practical effect to the questions discussed. The members forming the committee are Messrs. R. Ballantine, J. W. Moorman, Witty, Taylor, W. H. Lees, E. Beckett, Bevan, Geo. Gordon, Waterer, H. J. Jones, Geo. Stevens and D. B. Crane, with the officers of the society. Twenty-three new members and two Fellows were elected.

MR. A. F. BARRON.

TO THE EDITOR OF THE GARDEN.

SIR,—Having read the comments which have recently appeared in the horticultural press on Mr. Barron, the superintendent of the Royal Horticultural Society's garden at Chiswick, to-day I visited and criticised the work which was being carried on in the experimental gardens of the society. I was much struck with the great improvement in the condition of the garden and in the cultivation of the plants, the success of which is due to Mr. Barron. A few years ago when I was on the council with Mr. Veitch, just after the society's fortunate expulsion from South Kensington, and when we all hoped that its pernicious influences had been buried for ever, the council were compelled, from lack of funds, to starve the garden, the houses were dilapidated and the place was very much under-manned. To-day I found the houses for the most part in good working order, although two or three would be better if replaced by more modern structures. The collections of Apple and Pear trees I have never seen in better condition, and they contrast favourably with my own. I saw no evidence of blight. Of course, in such a large collection there always must be some trees which are out of health and which require to be renewed. The collection of Figs looked well. I know of no place where such a collection can be found. Those interested in Grape cultivation should make a study of the collection. The hardy annuals and herbaceous plants looked grand, and so did the plots allotted to the seed trials. I cannot conceive the reason why the council should have called upon Mr. Barron to resign. He is a man who is known to every horticulturist whose opinion is worth having to be straight and reliable—qualities absolutely necessary to give confidence to the trader and amateur. If it is true that the Chiswick garden and the fruit and vegetable committees (who visit many times in the year the garden and who are responsible for its management) have not been consulted by the council on this matter, and that outsiders have been called in to report, the council have passed such a vote of censure upon the members of these committees, that no man with a spark of self-respect could continue to serve upon them, and it is for them to resign in a body. If, however, it means a new departure in the management of the gardens, the Fellows should have been consulted and made acquainted with the proposed new scheme. If it is intended to attempt to make the gardens a profitable undertaking—a sort of bastard market garden—the market gardeners would very soon knock the bottom out of such a competitor. If, however, it is intended to convert the gardens into a third-rate nursery for the sale of cheap plants, the nurserymen can tell the Fellows that such a scheme must result in failure and bankruptcy.

But should the council desire to make the gardens into a public resort for nursemaids, the sooner the society gives up these gardens the better, for to apply the subscriptions of the Fellows to such a purpose would be little better than obtaining money by false pretences. It is my intention as an owner of an experimental garden, and who for over twenty-five years has had some slight acquaintance with the work which can be successfully carried on in such a garden, and as one who loves horticulture for horticulture's sake, to, at the first opportunity I have, ask for definite information as to the council's remarkable and unintelligible action. Should the answers which I receive not be satisfactory, I shall feel it my duty to submit such resolutions to the consideration of my brother-gardeners as the answers may seem to necessitate. I feel that for the society to lose the services of Mr. Barron (who has still many years of useful work left in him) would be nothing less than a disgraceful job, and prejudicial to the advancement of horticulture in this country. A. H. SMEE.

The Grange, Carshalton, August 26.

#### Proposed testimonial to Mr. A. F. Barron.

—A representative meeting of gardeners was held at the Hotel Windsor, Victoria St., S.W., on Tuesday afternoon, Dr. Maxwell T. Masters, F.R.S., presiding, to promote a public testimonial to Mr. Barron as a means of expressing in a tangible form the warm sympathy that is universally felt for him under the unfortunate circumstances of his leaving Chiswick, and in recognition of the long and honourable services which he has rendered to the Royal Horticultural Society as superintendent of its gardens and exhibitions, and to horticulture generally. It was unanimously resolved that a testimonial fund should be raised, and a general committee was appointed, with power to add to their number, Mr. William Marshall, Auchinraith, Bexley, Kent, and Mr. B. Wynne, 1, Dane's Inn, Strand, W.C., jointly undertaking the secretarial duties. It is proposed to elect a president and treasurer at the next meeting on September 10, and in the meantime the secretaries will be glad to receive the names of gentlemen willing to join the committee or to otherwise aid the movement.

### NOTES OF THE WEEK.

**Calceolaria alba** is a most distinct kind with linear leaves, each 3 inches or 4 inches long. The flowers are pure white and freely produced.—T. SMITH.

**Polygonum cilinode**, now in flower here, is a very charming slender climbing species; leaves reddish, flowers white, produced in the freest manner.—T. SMITH, *Newry*.

**Liatris pycnostachya**.—This is an excellent plant in groups where it does well and is effective as an autumnal flower. It comes to us from Mr. A. Perry's hardy plant nurseries at Winchmore Hill, a nursery to which we wish all success.

**Parnassia californica** has the largest flowers of all the kinds known to me. They are each about 2 inches wide, pale yellow in colour, and produced on stems about 1 foot high. It runs at the root, and even in this respect is quite distinct.—T. S.

**Pinks**.—Mr. Ladhams, Shirley, Southampton, charms us with the unusual sight of very fine blooms of perpetual-flowering Pinks at this time of the year. Mr. Ladhams says that the plants are as full of bloom and buds as in the spring.

**Giant Asphodel at Preston Hall, Dalkeith**.—I am sending herewith two photographs of *Eremurus himalaicus*, which may interest you. It flowered at the end of May and I took the photographs about May 31. The height was 5 feet 10 inches and the flower-head about 2 feet 6 inches.

I had my own photographs enlarged, but, as you will see, they are not nearly so sharp as the small ones, which I also enclose.—HENRY CALLANDER.

**Double Primroses**.—The copious rains after the drought seem to have started these into flower, and Mr. Perry sends us from the Hardy Plant Nursery, Winchmore Hill, a nice bunch of almost every variety of doubles—yellow, crimson, lilac—in fresh and excellent condition.

**Althæa ficifolia**.—This pretty Mallow, of which a coloured plate was given in THE GARDEN for January 12 of this year, is again flowering in the herbaceous grounds at Kew. Although long known and supposed to have been in cultivation about 300 years, it is a rare plant in gardens, but merits popularity for its stately habit, distinct leaf-age, and lovely blossoms. It may be briefly described as a single Hollyhock with clear soft yellow flowers and leaves like those of the Fig.

**Eupatorium purpureum**.—A bunch of this was shown on Tuesday, and at Kew lately we noticed a striking group of it quite 8 feet in height. It is one of these vigorous, coarse-growing perennials that might be used with fine effect in certain places. It is always attractive in growth, as it has deep chocolate-coloured stems, contrasting in colour with the large broad leaves, whilst at the present time its tall shoots are crowned with great branched heads of dark reddish purple flowers.

**Montbretia rosea**.—A large bunch of this was prominent in Mr. Prichard's group of hardy flowers at the Drill Hall on Tuesday, and it is such a distinct form as to merit a special note. Its flowers, about the same size as those of other Montbretias, are freely produced on tall, much-branched stems, whilst in colour they are of a very distinct rosy shade, quite unlike those of any other variety. Mr. Prichard says it has proved quite hardy with him, and passed last winter in the open ground unprotected.

**Rosa indica**.—During many visits to Kew this season we have never seen the plants of this lovely wild Rose without bloom, and now it is brighter than it has been all the season, each bush in the group bearing many brilliant flowers. The true perpetual blooming habit that we see and enjoy so much in the great family of Tea Roses is as apparent in this, one of the parents of that family, and it is a charming wild Rose, deserving a choice or favoured spot in the garden in association with its offspring.

**Gentiana linearis**.—In the interesting paper upon this genus in last week's GARDEN the above very fine species is omitted. It grows in an erect tuft 6 inches to 9 inches high, flowering in the freest possible manner and is not in the least fastidious as to soil or position. It is amusing to read the advice to pot off seedling plants of *G. acaulis*, &c., and to expect them to flower when three years old. Here the seeds are sown in the open ground, and such as *acaulis*, *septemfida*, *asclepiadea*, &c., always flower strongly the second year after sowing and are then large tufts.—T. SMITH, *Newry*.

**Campanula Vidali**.—Out of a number of seedlings of this which I raised a few years ago but two or three remain. During the winter months mice have a great fancy for the bark just above ground, which they gnaw off, with the result that the plant dies. It seems very impatient of disturbance at the root. If allowed to become pot-bound as the roots attach themselves to the sides of the pot, the process of forcing out seems to distress it much, and it is some considerable time after repotting before it recovers itself. It is, therefore, best not to delay shifting too long.—J. M., *Charmouth, Dorset*.

**Solanum Seaforthianum**.—The *Solanum* family contains quite a number of really beautiful flowering species, few of which, however, are seen in gardens, except at Kew. The species under notice was introduced early in the present century. It is a beautiful stove climbing plant, and those who have the space and convenience to grow it would certainly be delighted with its prolonged

display of pretty flowers. It is almost a counterpart of the better-known *S. jasminoides*, the flowers of about the same size as in this species, and similarly disposed in clusters, but they are of a distinct shade of light lilac-purple colour.

**Helianthus rigidus** Miss Mellish.—Perhaps the finest hardy flower to be seen at Kew at the present time is this handsome form of the Prairie Sunflower, which fills a large round bed and is a brilliant mass of rich colour, heightened in effect because so admirably placed, with a Yew hedge as a background and the bed isolated on the turf. The plants were wisely divided up and confined to single crowns planted at a considerable distance apart; consequently the flowers are finer individually and more numerous also, as with abundance of room the stems produce lateral flower branches down nearly to the ground. The flowers of this variety are large, made up of many rays of great width and extra richness of colour.

**Roscoea purpurea**.—This plant, although said to be quite hardy—and perhaps the only known one of the Ginger family that is so—seems to me more suited for pot cultivation. By its curious flowers as well as its foliage it may easily be taken for an Orchid. The blooms are not produced very plentifully at one time, but go on showing in succession over a considerable time. A pot specimen here has been flowering for over two months, yet it shows no sign of exhaustion, buds still continuing to succeed the expanded flowers. It is of the easiest cultivation; when it dies down it can be put aside in any plant house corner, in spring shaking it out and repotting in good rich loam and standing it under a sunny wall until it begins to bloom.—J. M., *Charmouth, Dorset*.

**The perpetual-flowering Acacia** (*Robinia pseudoacacia* semperflora) is all that the name implies, and a tree that should find favour and be generally planted in gardens. A few evenings back when walking along a quiet street in a London suburb we suddenly came upon three fine trees in profuse blossom, and the flowers made quite a conspicuous display in the twilight, although the full beauty of the trees could not then be seen. An inspection since by daylight shows them to be three unusually fine and flourishing specimens of this tree. Two or three graceful racemes of bloom hang from the still growing shoots, and there are yet other sprays developing that will maintain a succession of flowers for several weeks to come. There are very few trees that continue flowering to this late period, and certainly this *Acacia* is the finest of them all now.

**The yellow Balsam**.—It may be of interest to some of your readers to learn of a Scotch habitat of *Impatiens Noli-me-tangere* (the yellow Balsam), about which Sowerby was in some doubt. The plant was found growing in a damp situation in a shady wood near Wells House, Jedburgh, which place I have rented for three months. My daughters brought some of its flowers to me for identification, as they did not know it and had never seen it before. After examination and comparison I decided that it was the above-named plant, and so named it. I find there are many specimens distributed through the wood, and one which was uprooted and placed in some damp Moss in a pot in the hall was looking quite fresh and vigorous when I saw it yesterday (August 23) before returning here. This plant measured 3 feet 9 inches high by 2 feet wide.—O. O. WRIGLEY, *Bridge Hall, Bury, Lancashire*.

**Rudbeckia nitida** and **R. speciosa**.—The season when many yellow composites bloom is come again, and yellow is a predominating hue among the flowers of the time. If the best of the Cone-flowers and Sunflowers are boldly planted in gardens, there will be plenty of colour in the garden now. The two species here noted are both very fine at Kew. *R. nitida* is as yet little known and uncommon in gardens, but clearly it deserves to rank amongst the best of its kindred. A group of it at Kew is a mass of bloom, the shoots, which are about a yard in height, being branched pyramids of flowers. A coloured plate of this *Rudbeckia* was given in THE GARDEN for March

23 of this year. *R. speciosa* is better known perhaps as *R. Newmanni*, and it is needless to say much in its praise, as it is a popular garden perennial. Two beds filled with it near the Water Lily house at Kew command admiration and deserve mention.

**The Tamarisk**.—Although this is a familiar shrub in certain seaside gardens, one hardly ever sees it inland. It is a strange omission on the part of garden planters not to have a shrub that is a perfect embodiment of grace and beauty. This note is suggested by a beautiful specimen just seen in a little suburban garden, a noble plant indeed, as refreshing in its rich verdure and pleasing distinctiveness of habit within the smoke zone as it is in many an arid seashore district on the south coast. The plant in question was a large one, and had evidently been cut back closely at some period, but it is now a branching, spreading mass, with wands 12 feet in length, as graceful as Pampas plumes, and terminated by a long, drooping, branched raceme of tiny blossoms. A shrub of such a distinct aspect, and withal so easy to grow, might be made a pretty feature in gardens.

**The white Zephyr Flower** (*Zephyranthes candida*).—Although most of the Zephyr Flowers are rather difficult to manage and flower successfully, there is one very noteworthy exception in the species under notice. At Kew there is a quantity of it which forms a pretty edging to a narrow border of bulbous plants that require the sun and shelter that the situation affords with its southern aspect and reflected heat and light from the glasshouses along whose base the border is. Few bulbous plants grow thick enough to make an edging and flower freely as well, but the edging of this plant is a perfect one, whilst it sends up from its thick tufts of narrow Rush-like leaves a profuse and prolonged display of flowers. These are like a small white Crocus, and the resemblance is even stronger when one sees an edging such as that under notice with hundreds of pure white cups wide open in the sun showing their yellow anthers. A coloured plate of this pretty species was given in THE GARDEN of Feb. 15, 1890.

## OBITUARY.

**Death of Gustav Sennhulz**.—With regret I have to inform you that on August 24 M. Gustav Sennhulz, superintendent of the town gardens, Vienna, died here after a short illness, which he had caught on an excursion through Dalmatia, where he had gone to study the vegetation. The deceased was born in 1850 at Frankfort-on-the-Maine. He began his gardening career at Wilhelmshöhe, near Cassel; afterwards he attended the course at the Royal Horticultural School at Potsdam, and became landscape-architect with Siesmayer at Bockenheim, Frankfort-on-the-Maine. His successes made him also known in Austria, and as they were in the year 1884 in Vienna in want of a good landscape gardener, he was selected for this position. His loss will be deeply felt, more especially as the town is just now to be greatly enlarged, and consequently many new gardens will be laid out. Sennhulz also fought in the Franco-German war, 1870-71, and was wounded. He possessed the medal in remembrance of that war, and His Majesty the Emperor of Austria conferred on him the Golden Cross of Merit for his success in landscape gardening.—LOUIS KROPATSCHEK.

**The weather in West Herts**.—On the 22nd the temperature in shade rose to 79°, but since then the days have been cooler, although the nights have remained very warm. During the week the temperature of the soil at 2 feet deep has fallen 2°, and at 1 foot deep, 4°; the reading at the latter depth, however, is still about half a degree above the average for August. Rain has fallen on six days, the total measurement amounting to more than 1½ inches. Of this amount nearly an inch fell during a severe thunderstorm which

passed over Berkhamsted on the early morning of the 22nd. During the height of this storm rain and hail were falling for 10 minutes at the rate of over 3 inches an hour. The hailstones, which were very large, did much damage in the garden. Roses, Dahlias, and Chrysanthemums were greatly injured, and in some cases the flower buds were cut off. The air remains dry, while the winds have again come from some point of the compass between south and west.—E. M., *Berkhamsted*.

**Cypripedium Lord Derby**.—Allow me to point out to you a mistake in your issue of August 17. In the report of Orchid committee you state that Mr. Statter and Messrs. Sander and Co. received a first-class certificate for *Cypripedium Massaianum* superbum. It was only Mr. Statter that received that honour for a *Cypripedium* at the meeting. It was shown as Lord Derby. The cross of *C. Massaianum* is *C. superciliare* × *C. Rothschildianum*, the cross of Lord Derby being *C. Rothschildianum* × *C. superbum*, the flowers of the one quite different from those of the other.—ROBERT JOHNSON, *Stand Hall Gardens, Manchester*.

\*\* We are asked to state that the Orchid committee at the meeting on the 24th decided to certify the plant as *C. Lord Derby*, the name under which Mr. Statter showed it.—ED.

**Lime-loving alpine**.—Will any reader of THE GARDEN kindly give me a list of plants that succeed where lime is, and also a list of those that fail where lime abounds?—H. M.

**Destroying woodlice**.—We should be glad if you would give us a remedy for destroying woodlice or sow bug, as we have large numbers attacking seedlings and Orchids, and doing a large amount of damage amongst Ferns.—M. & W.

\*\* In pits or frames woodlice may be destroyed by pouring boiling water round the walls to which they betake themselves during the day, care, of course, being taken that the boiling water does not injure anything. In greenhouses or stoves place slices of Potato on the stages among the plants, examining these every day and destroying the woodlice which have congregated under them.—ED.

**Trees on warm soil**.—I have a border on the south side of my garden which is bounded by a paling about 7 feet high and planted with Larches 25 feet to 30 feet in height and 8 yards to 10 yards apart. These trees are needed as a screen for possible buildings on that side. The soil is sandy and impoverished by the roots of the Larches. What bright flowers or ornamental shrubs could you or any of your correspondents suggest for such a shaded and dry situation? What Evergreens would be likely to grow there? What Pine or Fir or other evergreen could be recommended as the quickest growing, most ornamental, and most effectual screen on a dry sandy and gravelly soil?—J. M. C.

\*\* Larches will not live long on such a soil, and our experience is that the best trees in such a soil are the Scotch Fir and the Yew. We should certainly substitute Evergreens for the Larch.—ED.

**Figures of Bamboos**.—As we propose to engrave illustrations of the kinds of Bamboos at present in cultivation in England and in the open air in Europe, we shall be greatly obliged to any reader who, having photographs of Bamboos, would favour us with a sight of them.

**Names of plants**.—*Mrs. Knox*.—1, *Broussonetia papyrifera*; 2, *Lonicera Ledebouri*; 3, *Heliopsis laevis*.—*L. M.*—*Odontoglossum citrosum*.—*Anon.*—*Triosteum perfoliatum*.—*J. M. S. P.*—1, *Campanula pallida*; 2, *Gazania splendens*; 3, *Centaurea ragusina*; 4, *Henbane (Hyoscyamus niger)*.—*T. Taylor*.—An unspotted form of *Oncidium Gardnerianum*.—*M. P. Thomas*.—Red Truffle (*Melanogaster variegatus*).

**Names of fruit**.—*A. C.*—1, Apple Early Margaret; 2, Plum Rivers' Early Prolific.—*J. E.*—1, Pear Fondante d'Automne; 2, Seckle.—*Dunham Massey*.—1, Apple Early Margaret; 2, Plum Reine Claude Violette; 3, Plum Oullin's Golden.

No. 1242. SATURDAY, September 7, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHARD AND FRUIT GARDEN.

## GATHERING AND STORING APPLES.

APPLES are without doubt one of the most abundant crops we have had for some years, and the question arises, what are we to do with them? If taken to market now the most that can be realised for ordinary samples in this district (Sussex) is from 1s. 6d. to 2s. a bushel, small ones not being worth gathering. The very finest samples are not worth more than 2s. 6d. By-and-by we shall be importing large quantities from various parts of the world, while our own fruit has gone begging. It is strange that we should not be able to make a better use of the abundant crops when they are close to our doors instead of rushing them on to the market at such a ridiculously low figure. The finest samples of Ecklinville, The Queen, Frogmore Prolific, Lord Suffield, Stirling Castle, Warner's King, and others of a soft nature that will not keep, instead of being rushed on to the market at 2s. 6d. the bushel, should be converted into chips or preserved for use in April and May, when fruit of all kinds is getting scarce. We have yet much to learn from our kinsfolk across the Atlantic before we make the best use of our supplies. I do not propose to go into the merits of such a business, but simply to point out, now that we have such a wealth of this important crop, the absurdity of gathering and storing a lot of worthless samples that are fitted for no other use than making cider. Had the trees been relieved of half the crop some two months ago the samples would then in all probability have been worth the trouble of being gathered carefully and stored in the most approved manner.

Many people gather their Apples too soon simply because a few of the most forward fall, instead of waiting till they leave the tree freely. Whenever fruit requires force to cause it to leave the tree it certainly is not fit to gather, and should be allowed to hang for some time longer. Gathering is too often done in such a careless manner that most of the fruit is so bruised in the operation as to render it unfit for storage, much of it going rotten before it approaches ripeness. Wicker baskets are by no means the best for gathering Apples in, as the twigs press against the fruit in such a manner as to cause many bruises. Whenever these are used, a little soft hay or Grass should be put on the bottom to prevent the fruit from coming into contact with the twigs. I prefer baskets made of chips for gathering, as they are more even at the bottom, and therefore do not cause any bruises. When gathered, the fruit should at once be taken to an open shed and there carefully sorted, retaining only those samples that are perfect to be stored for long keeping; these should be taken to a cool, dark room, which can be kept at an even temperature. It is a great mistake to put Apples on open lattice-work shelves, for on such much of the juice is extracted, causing the fruit to shrivel before becoming ripe. There are many advantages gained by allowing the fruit to hang on the trees as long as possible, and not the least amongst these is the lower temperature during the daytime the fruit will be exposed to after being gathered. Many

varieties, such as Northern Greening, Norfolk Beaufin, Reinette du Canada, Reinette Grise, Old Nonpareil, Court Pendu Plat, Baldwin, Baxter's Pearmain, Wellington, Winter Greening, Royal Russet, and others that do not ripen till after Christmas should be allowed to hang on the trees till well on into November. The exact time for gathering Apples can only be ascertained by trying if they will part from the trees freely. Some kinds, owing to their large size, are liable to be blown down by high winds, especially when planted in exposed places. For this reason shelter from the south and south-west should always be provided. Where Apples are only grown for home consumption a greater variety should be planted than when grown for market, as they will be required to extend over as long a season as possible. The long-keeping kinds should always be put in the coolest place when gathered, as by so doing their season will be prolonged. H. C. P.

**Plum Cox's Emperor.**—In neither private nor market gardens does this excellent Plum appear so frequently as it might do, for, according to my experience, there is no more prolific variety in cultivation. Trees planted against walls, or in standard, bush, or other form annually bear heavy crops; the fruit is also large, nearly round, and on our porous soil will hang for a long period without cracking. Planted against a wall and the roots supplied with ample nutriment, the fruit attains magnificent proportions and deep colour. Such fruit is fairly good for dessert, and when other varieties have been a failure I have frequently had to depend upon Cox's Emperor for a change on the dessert table, but unless, as stated, ample nourishment is given the roots the flavour is decidedly poor, and on heavily cropped trees quite disagreeable.—W. G. C.

**Apple Blenheim Orange.**—In every direction there are extraordinary crops of this esteemed Apple. In many of the Herefordshire orchards old trees that have scarcely produced any fruit for years are this season laden with fruit, which is of fair size and very clean. Already farmers and others are inquiring as to the value of Blenheims, and dealers are offering very low rates—indeed, as low as 4s. per cwt., informing the intending seller that the markets are glutted, and fruit will become cheaper still, as there are such enormous crops throughout the country. It is true that the rain came in the nick of time to save the fruit crop, which is much better than anticipated, but in face of the acknowledged short supply in America I believe that prices for good Apples will very shortly rise, and those fruit growers who have good crops of Blenheim Orange or any other large Apple will find it greatly to their advantage to keep their fruit until late in the season, when considerably enhanced prices will be realised. If the dealers bought that class of fruit now they would store it, and only re-sell again when they could make three or four times the price they paid for it.—W. G. C.

**Planting out Pines.**—The note by "J. C." (p. 145) is interesting. When at Frogmore last year I was shown some splendid Pines which were planted out. This of course is not new information as regards this famous garden, as at Frogmore they have been so cultivated for many years. My guide informed me that such treatment involved only a minimum of labour in comparison with plants grown in pots, although they did not show fruit so early. Has "J. C." or other correspondents noted that the best Pines are invariably produced in pits or low houses? If Pine growing should ever again become fashionable, pits or low houses will be found to be the best structures for their accommodation.—A. YOUNG.

**Raspberries.**—The article on Raspberries by Mr. Engleheart is very interesting, and well worthy of close perusal by all interested in

their culture. I shall certainly try leaving some canes at a distance from the parent stool to note their behaviour. If treating Raspberries as biennials increases the size of the fruit, it will be a system well worth practising, if only for a few fruits for dessert, as after the Strawberries are past, Raspberries are appreciated by many people for breakfast. I also quite agree with Mr. Engleheart as to leaving the canes their whole length. It was a hint I gathered from an old Lincolnshire gardener. There is really no benefit derived from shortening the canes, as many people suppose.—A. YOUNG.

## APPLES NEW AND OLD.

I HAVE had very forcibly brought to my mind this season a remark the editor made a few years ago in reply to a correspondent who had sent him a note regarding a new Apple he had been growing. The editor's remarks were to the effect that the raising and distributing of new sorts of Apples were being overdone, as there was plenty of good sorts of Apples for all seasons if cultivators would only give the older sorts as much attention as they gave the new. These remarks have been justified by facts that have come under my notice this season in the case of two sorts of Apples that have been a long while in cultivation. I allude to the White Astrachan and Duchess of Oldenburg. Unfortunately, I only planted a tree or two of these sorts when making a new garden seven years ago, as every season since they came into bearing I could have sold ten times the quantity of fruit. The fruit of both is so handsome, that there is a rush for it as soon as it can be had. Duchess of Oldenburg is the handsomer of the two and the greater favourite with my customers. Everyone may not perhaps like the juicy spicy flavour of this sort, but the majority of people do, while the taking appearance pleases everybody, and as a free-bearing and regular cropper there is no sort that surpasses it. It is as good for cooking as for dessert. White Astrachan is the earlier of the two, being ripe generally early in August, and on my bush trees, where the fruit is partially shaded by the foliage, it is a much handsomer Apple than Beauty of Bath and of decidedly better flavour. My experience is only another proof that in the case of Apples for market, the handsomest samples realise the best price. J. C. CLARKE.

Taunton.

## MORELLO CHERRIES.

IF trees worked on the Mahaleb stock could always be planted it would be a good thing for gardeners. In many instances through selecting such trees success has been attained, and before condemning the soil or garden as unsuitable for the good culture of Cherries, it would certainly be advisable, as recommended by "S. H. B.," to give these trees a trial. If Morellos are to succeed, the trees must be encouraged to root near the surface, and the less these are disturbed by digging or forking over the ground the better. This, followed by close cropping of the borders, is answerable for many failures. The best Cherry trees grown in the open as standards are always found on grass land, as in such positions the surface roots are obviously undisturbed. This conveys its lesson to be followed in gardens where the trees are trained against walls and with the roots in confined borders. So much do I believe in this detail being closely followed, that the border in this garden, which is devoted to Morello Cherries, is wholly given up to them. As each season comes round the trees carry heavy crops of fruit, but even non-disturbance of the soil will not ensure success without perfect drainage. A few of the trees are more marked in their healthy appearance than others, these at the time of planting having had extra attention bestowed upon them in the preparation of the stations. A well-drained soil is essential to success. Knowing this, after the soil was taken out, each station had a tile drain laid from the wall across the border into the wall.

drain, the bottom being further laid with old roofing tiles, and over these a layer of old brick rubbish. The soil when being filled in had an admixture of burned garden refuse and wood ashes, in which the trees have thriven admirably. Being a cold, clay soil, the back of the border is also raised quite 18 inches, sloping gradually to the front.

The best season for what pruning is necessary is immediately after the fruit is gathered. The wounds from the shoots so removed quickly heal over, when the laying in of the young growth should follow at leisure. Such work being rather tedious where there are many trees to go over, should all be finished in the autumn before the advent of cold weather. In selecting trees for planting do not upon any account have those which have been cut back several years in succession to keep them within saleable bounds, as the wounds so made are often the source of whole branches dying away after the trees have furnished a good extent of wall. The best trees are those of two or three years' growth. In laying out the framework of the future tree take particular care not to split the base of the shoot or branch at its junction with the older wood. Gumming at such points will surely follow, although the branches may not die away for a few years.

A. YOUNG.

**Apple Newtown Pippin.**—I certainly agree with Mr. Hendricks in his assertion that the Newtown Pippin is superior in flavour to either Ribston or Cox's Orange, and this I say after tasting the two latter from various counties in England. Good as the Ribston is, it certainly in my opinion lacks that refreshing juiciness so prominent in a well-finished Newtown Pippin. Cox's Orange from some soils and districts is of delicious flavour, while from others it eats dry and almost flavourless: in fact, I know of no dessert Apple more particular as to soil and locality. The Ribston does exceedingly well in this garden grown as an espalier on rather sandy soil, the flavour of the fruit being superior to that of any I have tasted in other places: yet for all that I must say that the very best samples are not equal to the Newtown sold at the West-end shops. As Mr. Hendricks says, many inferior samples of Newtown are imported, and it is after tasting these that comparisons are often made.—J. C.

**The Apple crop.**—It is a matter for congratulation with this season's Apple crop that, although somewhat partial, there is a capital yield from those varieties that we find most useful. The desirability of making yourself acquainted with those sorts most suitable for different districts and soils, and of ventilating the information thus obtained, cannot, I think, be over-estimated; it is a wonderful help to a gardener in a new place, or if he has to start planting soon after taking over any garden in a district comparatively new to him. The experience of several years goes to show that on this light sandy soil the three most useful dessert Apples are King of the Pippins, Adams' Pearmain, and Cornish Aromatic; that is, they are varieties that crop well and consistently, the fruit well up to the average in size, and keeping individually well. They succeed each other well, the King being followed closely by Adams', and Cornish Aromatic taking the place of the Pearmain. Earlier dessert varieties are not required to any extent: our best croppers of these are Mr. Gladstone and Kerry Pippin. Cox's Orange is very shy, below average in size, and with little colour. Much as I like the Apple I should not plant it again. The Ribston is a failure, and Claygate Pearmain, I imagine raised in the neighbourhood, but on very different soil to ours, is also a very shy cropper. Besides Cornish Aromatic, Cockle Pippin is decidedly one of our best late dessert Apples. It crops well, but individual fruits are not so large as those I remember from good trees in Sussex orchards. Kitchen Apples that do well with me are much more numerous; indeed a couple of dozen sorts might easily be selected in their respective seasons of which it might fairly be said that they were of nearly equal merit. Per-

haps for combined cooking qualities and consistent cropping, five of the best would be Lord Suffield, Warner's King, Cox's Pomona, Blenheim, and Wellington. This, it may be noted, applies to old trees of Blenheim. Here, as elsewhere, it is a long time before the planter has any return from Blenheim. Yorkshire Greening is a very heavy cropper as a standard; the spreading horizontal, almost drooping, growth of this variety is quite unique, and enables one to pick it out easily from among its fellows. I may note that our Apples are better coloured this year than in any previous season; as a rule they are very deficient in that respect.—E. BURRELL, *Claremont.*

#### OUTDOOR FIGS.

In the great majority of gardens most Fig trees were killed down to the ground-line by the severe frost of last winter, and many of the same have thrown up abundance of growth again from the soil. In most instances many more shoots have sprung up than ought to be permitted to remain, and if not already done, it will be advisable to immediately remove a portion of these surplus shoots, also pinching out the points of these growths that are allowed to remain. By doing this the wood will become thoroughly ripened and the buds so well developed, that a crop may reasonably be expected next year. At present much of the new growth is very tender, and if we should get a sharp winter again, it is very possible that all may be killed down to the soil once more, and not only a crop lost, but also valuable time. I have before alluded to the great benefits arising from summer and autumn pinching of Fig growths, but may be permitted to again strongly urge the importance of putting a check on all gross shoots by taking out the points, and so regulating the wood that each leaf has ample room for development. It may appear folly to allow so much room for the shoots, but if a crop can be secured every year by following out that system, the advantage must be evident to the most sceptical. I have a very old Fig tree here that my employer always looks upon with affection, not only for its age, but for the fine fruit it annually produces, and though the last winter's frosts somewhat crippled it, the size of tree was not much reduced, nor is the crop this year a failure, though not so heavy as usual. The question arises why this and other trees here should suffer so little, and in gardens round, equally, if not better situated, the trees should suffer so terribly. I have been wondering if pruning, or rather summer pinching, accounts for the difference. I am inclined to think it does, and as a case in point I may mention that a few weeks ago I visited the garden of Lord Tredegar, near Newport, Monmouthshire, and in the course of a ramble through this well-managed place with the gardener (Mr. Hollingworth) we came to a wall covered with Fig trees in capital health and bearing the heaviest crop of large Figs I ever saw outdoors. On remarking how well they had stood the past winter, the answer was, "No injury was done at all, and yet Laurels and other shrubs, also vegetables, suffered badly." On examining the trees more closely I noticed that Mr. Hollingworth pinched out the points of all shoots as soon as they had made three or four leaves, and as new growth was made the process was repeated. This system, he informed me, had been practised for many years and always with the most satisfactory results both as to the health of the trees and the crops they produce. I may add that I never saw that delicious Fig, White Marseilles, in such grand form outside as on the trees under Mr. Hollingworth's charge, the crop being enormous and the fruit of extror-

dinary size, proving that pinching suits the variety admirably. Brown Turkey was also in prime condition grown on exactly similar lines. There are many causes of Figs being unfruitful that pruning will not put right, and one of the chief, I believe, is a lack of potash in the soil, more particularly where the soil is light and sandy. This element enters largely into nearly all fruits, and when such a necessary constituent is exhausted within reach of the roots it is not astonishing that Figs are continually absent on the trees, or if they do appear the major portion turns yellow and drops prematurely. All sorts of reasons are given why this dropping occurs, such as drought, bad seasons, unsuitable soil and positions, in fact everything except the correct one. Where the trees have been barren for some time, I can recommend the application of potash in some form or other, and if the border is firm, with a mixture of lime rubble in the soil, the pruning also done as advised, a crop will be assured. The form in which I apply the above is muriate of potash at the rate of 2 ozs. to the square yard when the roots have a limited run. Kainit may be used in place of the muriate of potash, if more convenient, at double the strength named. The present is a very suitable period to apply either of the fertilisers.

W. G. C.

Ross.

#### FLOWER GARDEN.

##### CULTURAL NOTES ON HERBACEOUS PHLOXES.

GIVEN a selection of these Phloxes, such as that at p. 99 of THE GARDEN, we have at once the material for creating a rich display of their flowers. There is a deal of truth in the concluding remarks on the Chiswick Phloxes, "that they are rarely seen well grown in private gardens" and that they are "deserving of better attention." The summer of 1895 will long be remembered as one distinctly opposed to the well-being of this showy group of plants, for the long-continued heat and the entire absence of rain caused them in many districts to droop continuously. The result of this is blindness in many of the finest trusses, especially where the plants are somewhat crowded and in need of division. Apart from the heat, however, of this year there are other items, chiefly cultural, that are responsible for the half-hearted way in which these plants are grown, for if we would have their massive panicles of bloom in our gardens in perfection, they must be treated with the greatest liberality from the first. Unfortunately, these plants lend themselves too abundantly to division of the stools. I say unfortunately, because I believe that much unsuitable rubbish is in consequence distributed, and from which it is hopeless to expect any really good results. Stools that have stood for several years in one spot till they are a solid mass of weakly, puny stems and centres more like Boxwood than aught else can never produce fine heads of bloom even when transplanted into good soil. In those instances where the plants are more than three or four years old the best results are obtained from cuttings, but up to the age named these plants may be divided and replanted with very good results. Care, however, should be taken to employ only the younger parts of the plants, viz., the outer growths of the stools. The central growths are generally puny and weak and often refuse to grow in a satisfactory way. When employing the outer growths of the plant these should always be planted singly.

This is most important in the production of large, handsome heads of bloom. Such pieces as these, more especially if taken from ground plants, will a year hence produce from four to six heads of bloom according to their strength. It is now an excellent time to do this work while there is foliage remaining of the present year; indeed, there is no better season in the whole year for planting these herbaceous Phloxes than early autumn; they have then plenty of time before winter arrives to take good hold of the soil. A year or two since I gave a friend and neighbour a plant of an excellent white kind which I possess. It was a single stem, of the size of a small penholder and fairly rooted. When handing it over I pointed out that it possessed some half dozen breaks at the base, all of which would flower well next year, provided it was planted while still fresh. This was done, and to the surprise of its owner this tiny plant produced six massive heads of bloom of the snowiest white the following summer. In the following year, that is, the second year of planting, this same plant produced exactly twenty-four magnificent heads of bloom, an average of four to each of the stems of the previous year. As then seen it was the grandest single specimen of a pure white Phlox I have ever seen. But there is no difficulty in securing such results; indeed, any reader of THE GARDEN may have similar success by following a few simple, yet important, rules in their culture. In the first place it is most important that the soil be very rich and worked quite 2 feet deep. In this there should be no stint. Dig a hole 2 feet square in the ordinary garden soil, and work in about one-fourth of well-rotted manure; stir the latter well with the soil, but not too deeply in, for these Phloxes are also great surface rooters. Now return the soil, and finally put your plant quite firmly in the centre of the hole, and in a slight depression. This last will admit of thorough watering in dry weather. A mulch of manure may be added for the winter, but it is not essential. If a bed is required, a similar mode of preparation will be needed, but in this case it will be to the advantage of the Phlox that the usual rounded surface should be dispensed with. In summertime all that is needed to make these Phloxes a success is plenty of moisture at the root. Given a thorough soaking twice weekly, one of these being of liquid manure from the stable or cow house, well diluted, this will prove of great help at flowering time. Endeavour always to obtain fresh young plants from the ground. Failing these, all pot plants should be shaken clean out of the soil, never planting in the solid ball as received. These plants are easily increased from cuttings in autumn or spring, preferably the latter, employing a manure frame and the fresh young shoots of the year. Under such conditions rooting takes place in a month, and when hardened off, the plants should be put at once into rich ground. Many of these will flower the same year. Thus grown these Phloxes are a source of pleasure and a great attraction in any garden. A few beds of the most distinct kinds should prove decidedly ornamental in the large public parks and gardens in and around London. E. J.

**Androsaces.**—Mr. Wood, in his interesting and practical "Notes on Hardy Plants" on page 101 of THE GARDEN, gives the names of several Androsaces doing well in Yorkshire. To the names given I should like to add six more varieties, which, though they may not be suitable for the north of England, are certainly doing exceedingly well in Devon, Cornwall, Somerset, Surrey and Sussex. Why this should be so is

difficult to say, as these plants in their native homes inhabit very cold regions; but probably the more even temperature and moisture near the south coast are more congenial to them than the bleaker districts of the north, especially near large manufacturing towns where the atmosphere is laden with impurities. The varieties I would add are *Androsace pyrenaica*, *A. cylindrica*, *A. obtusifolia*, *A. lanuginosa*, *A. l. Leichtlini* and *A. Chumbyi*. Of these the first three are rare, and as they are of very slow growth they require a select corner to themselves, but the last three grow rapidly and should be in every garden. A year or two ago it was mentioned in THE GARDEN that *A. lanuginosa* would not do well in the north, but here in the south it grows without any trouble, and I could mention many places where plants of that variety have occupied the same position for a dozen years without showing the least sign of their vigour being used up.—F. W. MEYER, *Elmside, Exeter*.

**Galtonia candicans.**—Reference is made on p. 116 to this charming bulbous plant. I find it extremely useful in many ways. I take up some bulbs in the autumn, pot them into 6-inch pots and keep them cool and on the dry side during the winter in a cold frame. These grow strongly in spring and are most useful for planting in the flower beds in May. Treated as a hardy plant it is well worth attention; the deep green leaves and pure white bell-like flowers are handsome and much appreciated. In some gardens where the soil is somewhat light this *Galtonia* flourishes well, but in others, where the soil is inclined to be heavy, the bulbs suffer from too much moisture during the winter, and consequently do not flower so strongly. At Highclere Mr. Pope has a border 60 yards long and 6 feet wide quite full of it.—E. M.

**Cosmos sulphureus.**—This new introduction of Mr. Thompson's, of Ipswich, has been in flower in my garden for some time past, and has proved itself a vigorous half-hardy annual, of the easiest culture, and well adapted for town gardens. It is well marked by its five bright yellow, oval ray florets and neat foliage, divided into small linear-lanceolate segments. The plant seemed somehow familiar to me, and I find that there is a striking similarity between it and a woodcut of *Bidens humilis*, published some years ago in vol. xxvi. of THE GARDEN. Can any of your readers inform me whether the two names represent the same plant, or whether they are species of the same genus? It is well known that the two genera are closely allied to each other. I have not kept the description that accompanied the woodcut, so that my remarks are based solely upon the figure itself.—R. C., *Kensington*.

\*.\* In reply to the inquiry of "R. C.," I can only say that I received the seed of *Cosmos sulphureus* (Cavanilles) from the Imperial Botanic Garden, St. Petersburg, in the spring of last year, and have assumed the correctness of the name, notwithstanding the inapplicability of the specific designation *sulphureus*, the colour being, as stated, a bright full yellow.—W. T., *Ipswich*.

**Lychnis fulgens Haageana.**—Very pretty and effective are two beds of this perennial which I noticed at Kew a few days ago. It certainly justifies the name, owing to the intense brilliancy of the flowers, which are each nearly 2 inches across, and include nearly every shade of colour from bright scarlet to pure white. The plant grows to a height of 1 foot and is of very easy culture, succeeding admirably in almost any ordinary garden soil. The many variations in colour produce a most pleasing effect. I was so impressed by its appearance in the beds at Kew, that I have decided to use it for a similar purpose next year.—H.

**Limnocharis Humboldtii** is a fit companion for even the best of the hybrid *Nymphaeas*. It should find a place in every water garden, notwithstanding the fact that it is not perfectly hardy except in very warm sunny positions in the south. It will, however, succeed if a little shelter is afforded, and if this is done the slight trouble

will be amply repaid. It is very distinct in character, graceful and free-flowering, continuing throughout the summer. The flowers, of a rich golden yellow colour, single, with but three petals each, in shape closely resemble those of a *Convolvulus*. The length of each petal is about 2 inches and the flowers are beautifully fringed. The leaves, which are of a lively green colour, float upon the surface of the water.—H.

**Aponogeton distachyon** (Cape Pondweed) is quite hardy in shallow water. It produces large white, Hawthorn-scented flowers, the scape two-spiked, the spikes varying in length from 2 inches to 4 inches. The flowering season is very prolonged, lasting from spring till autumn. When planting it in a lake, the young plants should first be established in a large pot or basket in a tank or fountain-basin, and then be put out into their final position, where the water should be clear and free from weeds. This ornamental little plant does well at Chiswick in the fountain by the large vinery.—H.

FLOWER GARDEN NOTES.

**SPECIALITIES.**—It is generally in the herbaceous and annual classes that one meets with new things that make a unique and striking display in bedding plants or those that are classed as such. Anything very much out of the common or that is a great improvement on existing varieties only makes its appearance at rare intervals. With the more easily grown plants it is on the other hand especially noticeable that not a season passes but one is able to pick out several things which, if not absolutely new, play for some reason a very important part in the flower garden arrangements. I had a packet of seed this year of a new form of *Nicotiana affinis*, and sowed it with the firm impression that it was not likely to turn out any improvement on the type. It is, however, a decided improvement, the plant being more sturdy and the individual flowers larger. At the time of writing (August 20) there are many plants from seed sown at the beginning of February that are nearly 4 feet high and quite as much in diameter. This is a capital dry weather plant. If one can once get it on the move it is quite indifferent to a prolonged drought. I have been interested this year in a batch of *Tropæolum speciosum*. Doubtless many readers of THE GARDEN have seen the recommendation "that the sun ought never to shine on the plants." This statement, however, may be very considerably qualified. Given an old stump of large size that has to be clothed with foliage, the Couch-like roots of the *Tropæolum* may be planted on the shady side, not necessarily quite out of the sun, as one of my best clumps gets all the afternoon sun. The ground should be deeply dug and well manured, using a heavy manure if the soil is naturally light, a surface mulching being added after planting to keep in the moisture. A few twiggy Pea sticks inserted in the ground with their tops leaning towards the tree stump will afford the *Tropæolum* a support in the early stages of growth. I suppose after the winter of 1894-5 one cannot praise too highly those varieties of Carnations that came safely through and furnished an excellent display during the summer. Of Mrs. R. Hole, Raby, and a deeper Pink than Raby with Clove foliage I did not lose a plant, the next three best being Murillo, Sir Beauchamp Seymour and Ketton Rose in the order named. The wealth of bloom, too, provided by individual plants was extraordinary and quite unexpected when one remembered the dry, withered-up appearance of the plants after the break up of the February frost. The weather has been very favourable for the layers ever since they were put down. I should like to say a word in favour of Tufted Pansy William Niel, not because it is better than many others from a flowering standpoint, but because of its unique colour; it makes a lovely bed associated with pale Fuchsias, a few plants of Marguerite, or the Sweet Tobacco named at the head of these notes. Writing of Fuchsias reminds me that the Duchess of Edinburgh, scarlet sepals and

purple corolla, a vigorous variety and very free has proved itself one of the best of that colour for outdoor work. Despite its vigorous habit it keeps very sturdy, and holds its flowers longer than most varieties. I have a capital bed just at present of *Achillea ptarmica* The Pearl quite a sheet of white. It was planted last autumn, and, bearing in mind its leggy habit, the shoots were pegged here and there to cover the bed so soon as they had attained a fair size, the result being a very well furnished bed, the heads of flower standing a little over 2 feet from the ground. A very pleasing and effective contrast on borders is afforded just at present by clumps of this *Achillea* similarly pegged in close proximity to nice-sized groups of *Montbretia crocosmiiflora*. The rains which came towards the end of July, followed by another spell of warm weather, were a wonderful help to the Sweet Peas. We were late with them this year, not being able to sow until nearly the middle of March: the birds helped themselves rather liberally, and they made headway very slowly through the long drought. They have now, however, thoroughly furnished the sticks, and, given prompt and constant removal of seed-pods, will remain in flower a long time. I am decidedly in favour of pronounced as opposed to uncertain shades, and think Emily Henderson, Captain of the Blues, Princess Beatrice, Firefly, and Splendour are hard to beat. As with many other things, a good mulching of manure was of wonderful service to Sweet Peas through the late summer. Of annuals previously recommended in these notes, I have found the miniature Sunflower and the varieties of Malope and Cosmos extremely useful, making a brave show on the borders and invaluable in a cut state. All, too, possess the merit of holding out well until the season for border flowers is getting nearly over. I came across an interesting plant the other day in a cottage garden in *Salvia sclarea*, known locally as Clarey. There was quite a large patch of it, and as in addition to the quantity it had evidently been carefully tended, I had the curiosity to inquire the object of such extensive and careful cultivation, and was told it was grown annually for the purpose of wine-making. I can personally vouch for the fact that it really does make an excellent light wine.

**STAKING HERBACEOUS PLANTS.**—Although I do as little of this as possible, the heavy rains have caused such strong growth, that in many cases a little support is absolutely necessary, particularly so with plants with heavy foliage that have grown higher than usual, or with very large heads of flower, as some of the newer *Phloxes*. There is nothing better for the purpose than round iron stakes of half-inch or three-quarter-inch diameter, sharpened at the one end, and varying in height to suit the requirements of the plants. They are naturally at the outset more expensive than wood, but really cheaper in the end, being practically indestructible. The tying should be so arranged as to avoid unnecessary formality, simply to keep the plants from breaking down.

**THE INCREASE OF HERBACEOUS PLANTS.**—The power of self-production with little trouble to the cultivator in many herbaceous plants is very great, and it may be safely said, that given a few plants of each species, their numbers may be increased even in one season to almost any extent. In a recent note I referred to the marvellous crops of seedling *Polyanthuses* that were springing up where old seed-pods had not been removed. The hoe was put through the bed to demolish the seedlings, but again after the heavy rain they are making their appearance very thickly. In a portion of the pleasure ground where *Rhododendrons* were rather thin a few plants of *Foxgloves* were put out, and from the small beginning the sides of the hill are thickly studded with the plants at all points where there is a little open space. The *Delphinium* is another plant that increases very readily, countless seedlings being available if the old flower-spikes stand long enough for the seed to ripen, and a similar carpet of seedlings is always to be found under some of the dwarf *Campanulas*. I generally look sharply

after the seed-pods on Tufted Pansies, but if a few are missed, the seedlings make their appearance in considerable numbers, and very useful varieties are sometimes obtained in this haphazard way. The power of reproduction at the root is also in some herbaceous plants very pronounced, so that once established it is not so much a question as to preserving the species, but (if that is deemed advisable) how best to get rid of it.

Claremont.

E. BURRELL.

## HARDY PLANT COLLECTING.

TO THE EDITOR OF THE GARDEN.

SIR,—I have read with great pleasure and interest Mr. Burbidge's most sensible article contained in a recent issue. I may say that my previous letter elicited some replies (from Mr. Kingsmill, M. Van Tubergen, &c.) expressing readiness to join in the scheme. But without doubt the difficulties mentioned by Mr. Burbidge as necessarily associated with the employment of a collector and the absence of any well-known name in connection with the undertaking have rendered any general response impossible. But the prospect of tapping the hidden hoard of beauty which most surely lies waiting for us in the great unknown chain of the Southern Andes or equally unknown mountainous chains of the north is too good to be let slip for any objections so easily removed.

Mr. Burbidge's suggestion that, instead of risking everything in the costly and venturesome experiment of a collector, we should endeavour to utilise the innumerable outposts of humanity which are already stationed on the borders of the wilds we want to get at seems to me a most excellent one. We should practically be able to spend all our funds in subsidies to consuls, missionaries, trappers, traders, in fact all sorts and conditions of men in all parts of the world, to whom the chance of earning £10 or £20 in such an easy way would be highly acceptable. I say that we should be able to spend all our funds on the direct object of our scheme, because I am sure that there are several of us who from sheer love and interest in the thing would be glad to take turns at the secretaryship, and learn something of the extraordinary ways in which life goes on in some of the out-of-the-way parts of the world. It is particularly pleasing to think that the plan will probably be increasingly effective with each succeeding year as we learn the best channels in which to spend our money. I trust also that it will be an essential article of our creed that the national collection at Kew shall be enriched by specimens of all the new things we get. It will certainly be a most unusual and entertaining sensation to think when the little green shoots first put their noses up above the ground that perhaps they are going to be something as good as *Heuchera sanguinea* or *Chionodoxa sardensis*.

ARTHUR K. BULEY.

**Francoa appendiculata.**—For the last ten years I have grown this *Francoa* in the open border. With me the foliage dies down yearly: many of the crowns are killed, too, during the winter, in spite of a mulching of half rotten manure put over them in the autumn. It is, however, of such free growth that in the spring it quickly revives, and bears its pleasing flower-spikes freely.—E. M., *Bishop's Waltham*.

**Stock Princess Alice.**—This now well-known white Stock is grown in some places not only on borders for cutting, but on beds in the flower garden. It has been found to be such a continuous bloomer that there is no fear of a falling off in this respect from June to November, provided, of course, the plants are well managed. Previous to planting, the beds should be thoroughly well manured and the plants well soaked with liquid manure at frequent intervals, the surface of the beds also being well mulched. Another very important point is to remove all flower-spikes as soon as they are past their best. This

lovely white Stock is seen to the best advantage when surrounded by an edging of *Amaranthus* or *Iresine*. It blooms so profusely and has such a branching habit, that many spikes may be cut from beds in the flower garden without being missed.—J. C.

**Bedding Begonias.**—There is something of a race being run now between the large-flowered Begonias and other smaller-flowered, free-blooming forms as to their qualifications for summer bedding, and also the fibrous-rooted forms, of which, too, we have so many at varying heights and of diverse colours and such wonderfully profuse and persistent bloomers. *Begonia Worthiana* is now seen in many gardens, and it is a great favourite at Hampton Court Palace. It has long been employed largely, but it seems possible that even so good a thing may presently be displaced by some of its progeny from a cross with a large-flowered crimson form, as there are in a couple of beds huge plants of such production in wondrously rich bloom just now, and these constitute the finest bedding Begonias I have yet seen. The flowers are of moderate size, single and drooping, but borne in immense profusion.—A. D.

## TUFTED PANSIES.

It is pleasing to note that these are being much more freely used in public gardens in and near London than was formerly the case. The only fault seems to consist in planting rather too thickly, as they come into a solid mass of foliage by summer, and the flowers are not so good as would be the case if each plant had more room for development. Pansies have great value for beautifying gardens early in the year, but they can also be employed for embellishing them during the summer months. They may be had in capital condition through July and August by simply modifying the cultural details. For summer display the seeds should be sown in a cold frame not earlier than the end of August or in gentle warmth early in April. These small plants will not commence to flower freely until the end of May, and they will yield blooms of excellent quality for three months. They should be put into good ground that has been enriched with some well-rotted manure, and in light soils a mulch of the same will be beneficial. It may be said that having now-a-days so many fine summer blooming flowers we do not need Pansies at that time of year, but there are many gardens where dwarf-growing things are needed and glass accommodation for preserving or raising bedding plants is scarce. Where such is the case Pansies would be found very useful, as they are so suitable for small beds or for forming an edging to larger ones. In the case of autumn-planted Pansies that are to flower in spring, much may be done to prolong their effectiveness by keeping the seed-pods picked off and watering when needed, a little weak liquid manure occasionally being beneficial. Plants treated in this way will continue effective till August is far advanced. Last spring I very much admired a nice lot of Pansies that formed an edging to a bed on the Grass plot of a small front garden. About the middle of June the owner pulled them up to make room, he said, for bedding plants, and their place is now occupied by *Lobelias*, which are not nearly so showy, and certainly do not give the variety that the Pansies did. They were just in full beauty when they were pulled up, and they would have been good now had they got a little attention. Close by a cottager has two beds which were planted with Pansies at the same time, and they have been a mass of bloom from May up to the present time. Through the dry weather he kept them watered, and I see but little difference in the size of the blooms now and two months ago. Pansies do very well in a north aspect in the summer months, and in a hot, dry time the blooms come much better there than in the full sun. The plants must, however, get plenty of light and air, or they will become too weak to produce good blooms. J. C. B.

**WHITEHALL, SHREWSBURY.**

**THIS** is a beautiful old house built of red sandstone in the time of Queen Elizabeth, and though its walls are much worn by the storms of centuries, it is still in a perfect state of preservation and a delightful residence in many ways.

whilst the outlying parts of the town now surround on all sides the ancient walls that enclose it. Inside of these walls, however, one hardly realises the proximity to a large and busy town, and the simplicity of the gardens is in perfect harmony with the situation, for anything like a

looks out upon a lawn that could not be better adorned than it is by the few fine Larches and Hawthorns which stand upon it. The Larches, of which there are four, are venerable specimens, beautiful in aspect and branch-spread. A straight gravel walk just cuts off the lawn from the house, whilst little Box-edged beds and borders stretching its entire length on one side are filled with Roses, Pansies, and other flowers, such as Geraniums, Verbenas, and Petunias. At the end of this walk and at right angles to it is a little plateau or gravel terrace, from which one can look over the town and get pretty peeps of the distant landscape bounded by hills at the extreme limit of the view. On the opposite side of the house the lawn is flanked with shrubs, which hide one of the walls that enclose a kitchen garden of the good old sort, with square or rectangular vegetable plots and mixed flower borders. The Peaches on these walls were very fine—indeed, as large as we see them grown under glass, and with that deep colour on the sunny side that is only fully developed in the open air. The coping of these walls is a little flower garden in itself at certain seasons, with Wallflowers and Snapdragons the chief feature. The great attraction of Whitehall, however, is its ancient Walnut tree, the like of which, or indeed one at all comparable to it, we have never seen. It stands upon and extends beyond a plot of Grass beside the carriage entrance to the house. Its stem at 4 feet from the ground girths fully 16 feet, whilst at about 4 feet higher, where it divides into huge limbs, it would girth several feet more. The huge branches are in many cases supported by props, and there is hardly one but what has been shorn of half its length by storms, yet the tree is still vigorous. The diameter of its present spread of branches, as tested in two directions, is 36 yards. The Mulberry also grows and fruits well here.

**KITCHEN GARDEN.**

**SOWING SEEDS.**

A GREAT proportion of the seed sown annually in both flower and kitchen gardens fails either to germinate or to give satisfactory results, hence seedsmen are made scapegoats for what is really due either to the ignorance or carelessness of others. Probably more disappointments have occurred in relation to spring-sown crops this season than in any other within living memory, the ground during March being in many instances in quite an unfit condition for the reception of the seed owing to the long-continued and intense frost, and it is to be hoped that many who have hitherto clung to the old practice of sowing seed of early vegetables on a certain day of the month, regardless of the fitness or otherwise of the soil and weather, will have learnt a life-long lesson. Quantities of seed of the early hardy varieties of Peas rotted in the ground, gardeners being anxious to get it in, fearing that the first pickings should be behind the usual date, Early Mazagan and Green Windsor Beans suffering the same fate. As a rule, too little forethought and care are bestowed on the preparation of the ground for seeds of early vegetables. How many allow the snow to melt and seak into the early borders instead of having it raked off, and how few there are who care to go to the trouble, as they say, of preparing during a slack time in winter a good heap of burnt refuse, leaf-mould, the sweepings of roads and drives, wood ashes

*Whitehall, Shrewsbury. Engraved for THE GARDEN from a photograph by the late Mr. J. L. Robinson, C.E., Dublin.*

It is the property of Archdeacon Lloyd, who resided there until his removal to the rectory of Edgmond, in the same county, and is now tenanted by Mr. T. J. Provis. The house is situated in one of the prettiest suburbs of Shrewsbury, but its grounds are not extensive,

pretentious display would certainly contrast harshly with the old house and its garden walls in part mantled with Ivy, and where unclothed none the less charming in the warm colour of the weather-beaten stone. The engraving we give shows the south or garden front, which

and similar ingredients invaluable for digging into early borders or for placing over seed Potatoes before finally filling in the drills. If those who have the means for doing this, but who now ignore it, would give it a trial, they would ever after practise it, even from a labour-saving point of view, especially where the soil is not of the lightest and warmest.

Sowing seeds by rule of thumb and when the season has advanced is a mistake. How often is a plot of Cauliflower or Cabbage which has drawn every particle of moisture from the ground cleared off and Beans or Peas sown immediately, a partial shrivelling of the seed, and consequent weakly growth, inevitably following. Far better would it have been to have waited a week, and then if no rain had fallen, to have well soaked the drills, sowing the seed twenty-four hours afterwards. This little extra trouble cannot be compared to the worry inseparable from failing crops and frequent blanks in the supply of summer vegetables. Even when the ground is not really dry it pays to give a watering as above described, as should a few weeks of drought occur, the seed takes no harm till rain comes. Small seeds, such as Cabbage, Cauliflowers, and Lettuce, often fail through being sown on dry ground, the meagre sprinklings given to the thin coating of soil covering them often being lost in evaporation during hot, dry times, and no encouragement given for the descent of roots. The best way to ensure success is to well moisten the ground to the depth of 6 inches the day previous to sowing, and to cover the surface with mats, bags, or litter until the seed germinates.

Such subjects succeed well sown in the partial shade of espalier trees, always provided the seedlings are thinned early and freely. I can speak from experience of the great advantage of slight ridges for early sowings of French Beans, especially of such varieties as Canadian Wonder, which are prone to rot in wet weather. Thus elevated, the surplus moisture escapes and the seed is saved. The ridge system should always be adopted where the early round-seeded varieties of Peas are sown in the autumn, a practice now almost extinct, gardeners finding that sowing in heat, duly hardening off, and planting out in March secure better results and save the worry of a constant warfare with mice. Sowing thickly, although so often denounced, is still commonly practised, the idea being to secure a good plant, but what is gained in quantity is lost in quality, as in nine cases out of ten thinning is not carried out in the nick of time, and crowding, with its attendant evils, follows. It is seldom that Peas are thinned, even if pressing each other in the rows, yet a little time devoted to such work would be a decided gain in the end, nothing being more antagonistic to a good yield than crowded haulm, which cannot possibly receive a maximum amount of sunshine and air. Amateurs frequently err in sowing Carrots, Onions, Beet, Parsley and similar things too deeply. When so sown, it matters not how good the seed, patchy and unsatisfactory crops alone can be expected. I have made it a rule for years to scuffle the surface of the ground several times in the forenoon of sunny days before sowing my early seeds in the kitchen garden, drawing out the drills at that time also that the sun may warm them, sowing and filling in during the afternoon, and am convinced that if attention be given to these little details—which some might call coddling—not only better, but much earlier crops of vegetables are obtained than by sowing at any given date without any special preparation of the soil. Many tender annuals which ought to be raised in

heat and afterwards transplanted are sown in the open and too early in the season, amateurs especially erring in this respect. In conclusion, I would urge upon young gardeners the necessity of making a special study of this seed-sowing question, it being the pivot on which must turn much of their success or otherwise in future years.

J. CRAWFORD.

**Kidney and round Potatoes.**—The distinctions which formerly existed between kidney and round Potatoes have been of late so broken down by the introduction of intermediate forms, that I urge committees wherever I can to do away with what is now a senseless division and invite Potatoes at shows as white and coloured only, as then there can be no question as to distinctness. How frequently do we see Beauty of Hebron long and the same variety short shown as both kidney and round in respective classes. The same thing is constantly occurring with long and round forms of Satisfaction, to quote only two sorts. But the distinctions of round and kidney serve no good purpose. It is true that every variety of Potato may have its distinguishing characteristics, but so many are of an intermediate long form literally neither round nor kidney, that they cannot be classified. If the old division be insisted upon in schedules, then the sorts eligible in each class should be specified. There can be no question as to the status of Snowdrop or Pizetaker as kidneys or of London Hero or Windsor Castle as rounds, but the bulk cannot be so classified.—A. D.

## BOOKS.

### MANURES AND THEIR APPLICATION.\*

SEVERAL works, more or less elaborate, have of late years been published under very similar headings, but there is yet good room for this little pamphlet. Originally delivered in the form of a lecture, it was, at the request of its hearers, published in a cheap form, the author taking the opportunity of enlarging the work and giving fuller details where this was considered desirable. As Mr. Dyke states in the preface, there is not much that is new in his lecture, and he very rightly and properly gives a list of earlier writers on the subject to whom he is indebted for much valuable information. He has succeeded in compiling a really serviceable series of hints bearing upon the principles of manuring and the composition of manures, presenting these in a form that need not bewilder the merest tyro. All that the ordinary gardener, professional or amateur, need know about manures, the need for these and their application is given, and if on mastering this elementary pamphlet a student becomes ambitious to know more, there are plenty of works of a more advanced character abounding in technical phrases and tabulated information that will interest, if it does not exactly greatly instruct the reader. In the introductory chapter the various manurial elements and their uses are briefly discussed, a point being made of the fact that organic manures, notably those obtained from farmyards, blood and such like, are extremely slow in operation during cold weather, this pointing to the necessity for applying manures during the cold months in the form of nitrates, or otherwise growth of crops must be slow. Next comes "The study of manures, as to what they are and what they do," followed by a description of the different manures in use. These latter are divided into two classes—general and special. The former comprise farmyard manure, guano, ammoniated guano, native guano, manures from fowls, pigeons and such like, vegetable refuse and green crop manuring. These are supposed to contain nearly all, or quite all, the in-

\* A lecture delivered to the Chesnut, Wormley and District Horticultural Society by W. Dyle, Turnford, Herts.

redients required by plants for their nutrition, whereas special manures are more or less incomplete. Included in the latter category are sulphate of ammonia, nitrate of soda, blood, soot, hoof and horn, shoddy and wool waste and leather scutch, all of which are of a nitrogenous character. Then we next have dried fish manure, bones, dissolved bones and phosphatic guano, these supplying both nitrogen and phosphoric acid, nitrate of potash (better known as salt petre), giving nitrogen and potash. Phosphoric acid and potash are supplied by phosphate of potash, and those manures which supply chiefly phosphoric acid are mineral phosphates, Thomas phosphate, or basic slag and superphosphate of lime. Manures given as supplying potash are sulphate of potash, muriate of potash, kainit and carbonate of potash. Other special manures alluded to are sulphate of iron, lime, salt, magnesia and liquid from manure heaps. How to apply these elements separately or in mixture is briefly set forth, not the least valuable advice being that which gives appropriate mixtures for a few of the most important crops grown in the vegetable garden; the author, however, being careful to add that "we must remember that the property and composition of soils determine what kind of manure it is best to apply. On this portion of his subject he might have enlarged with advantage.

W. I.

## FERNS.

### TODEAS.

WITH the exception of *Todea barbara*, a very excellent Fern with several *aliases*, and one which is noted for the peculiarly leathery texture of its fronds, all other *Todeas* at present in cultivation have finely divided, very fragile fronds of a more or less transparent nature. All *Todeas* require greenhouse treatment, and all are much benefited by close confinement. Although a few degrees of frost are not hurtful to them, and although such as *T. hymenophylloides* and *superba* can stand the effects of severe frost, they certainly do not appear to derive any special benefit from exposure to cold. A compost of peat and silver sand, to which a small portion of partly decomposed *Sphagnum* may be added with advantage, is that in which *Todeas* thrive best. The hot dry atmosphere of the summer months is certainly their greatest enemy, and special care and attention are required to keep up a constant supply of humidity in the *Todea* case. No sun should ever be allowed to shine on *Todeas*, and condensed moisture is absolutely necessary to their well-being; this, however, should be obtained as much as possible without watering overhead, and if this must be done at any time, rain water only should be used for that purpose.

*T. BARBARA*, also known in gardens under the names of *arborea*, *africana*, *rivularis*, although also a native of New Zealand, Tasmania, Natal, and Cape Colony, is a plant of totally different habit and structure, and as a decorative Fern has very few equals. It is a robust-growing plant, forming in time trunks of extraordinary thickness in comparison to their height. Its fronds, which are of a leathery texture, dark green, shining and naked on both sides, are produced in great quantities and often measure 3 feet to 4 feet in length; their leaflets are closely set and furnished with narrow pinnules, the edges of which are more or less distinctly toothed. Good-sized plants of this species, which require greenhouse treatment, but which does not suffer from exposure to the air, can be grown in comparatively small pots, and its lasting qualities are unsurpassed by any other known Fern used for indoor decoration. A mixture of two parts peat and one part loam is that which suits it best, and it delights in having its fleshy roots kept in a constantly moist state.

*T. HYMENOPHYLLOIDES*, or (as it is called) pellucida, is probably the most robust and the most easily grown of all known species and varieties. It is a native of New Zealand, and produces from a thick, fibrous trunk an abundance of gracefully arching fronds, each frequently measuring 2½ feet in length by 1 foot in breadth. Their leaflets are, or appear to be, dark green in colour, but if a sheet of paper or any other white object is placed at the back of them it is soon apparent that they are of a very transparent nature. This species reproduces itself readily from spores and forms good-sized plants in a comparatively short time.

*T. SUPERBA* (here illustrated), which is known in gardens as either the Prince of Wales' Feather

in height and is of a woolly nature at the interior and densely fibrous on the outside. Its very handsome fronds, which in its own country frequently measure 4 feet in length, seldom exceed 2½ feet under cultivation: they are from 6 inches to 10 inches broad and finely divided, but are so thickly furnished with leaflets as to appear quite thick and of a dark green colour, although their transparent character is revealed as soon as a white object is placed behind them. This beautiful species is identified at first sight by the character of its fronds, which are furnished with leaflets nearly to their base, showing hardly any stalk, a character which is not shared to that extent by any other species at present known. *T. superba* can only be propagated from spores, but few are

in height, but which has never been known to assume the dimensions of a stem. It also reproduces itself freely from spores, which are produced in abundance.

*T. MOOREI*, of comparatively recent introduction, is a beautiful plant. Native of Lord Howe's Island, and so very similar to *T. grandipinnula* of Moore, that it is difficult to distinguish one from the other. The trunks, which at various times have been imported into this country, do not show the fibrous character peculiar to those of the foregoing species: they are of a more woody nature and furnished with fewer roots. The fronds, which are large and massive, are delightfully transparent: their leaflets being larger than those of other species show this character to great ad-

*Todea superba.* From a photograph by Miss Willmott, Warley Place, Essex.

Fern, or the New Zealand Filmy Fern, and as the Crape Fern in New Zealand, is certainly the most beautiful, as also the most striking, of all the known species. It is also the oldest known *Todea*, for the specimen in Hooker's herbarium was gathered by Forster in New Zealand during Captain Cook's voyage, although it was not seen again until 1838, when the Rev. W. Colenso (to whom its discovery is generally attributed) detected it on the Tongarou Mountain and three years later on the mountain range near Waikare Lake. Like *T. hymenophylloides*, *T. superba* produces its foliage from a somewhat erect, fibrous trunk, which has never been known to attain the dimensions of a stem, as it reaches at the most 18 inches

the places where these are known to germinate spontaneously.

*T. FRASERI*, which is a native of New Caledonia and also of the Blue Mountains, Australia (where it is said to be rare), is the strongest growing and also the least transparent of all the *Todeas* with finely-divided fronds with which I am acquainted. Its fronds, which under cultivation each attain from 3 feet to 3 feet 6 inches in length and 1 foot 6 inches in breadth, are borne upon stalks which when young are of a light red colour, forming a very pleasing contrast with the bright light green colour of their leafy portion. These (as in the foregoing species) are produced from a fibrous trunk, which sometimes measures 1½ feet

vantage. It has not been ascertained yet whether this species will reproduce itself or not from spores.

The list of known species of *Todeas* with transparent foliage is brought to a close with the lovely

*T. WILKENIANA*, which Mr. Baker classes as a mere variety of *T. Fraseri*. From a botanist's point of view this may be correct, but for all garden purposes the two plants are sufficiently distinct to be kept apart. In the first instance, while the foliage of *T. Fraseri* is hardly transparent, that of *Wilkesiana* is decidedly so: then the fronds of *T. Fraseri* are produced from a

trunk or clump of a fibrous nature, having much the appearance of that of an *Osmunda*, whereas those of *T. Wilkesiana*, which is a native of Fiji and the New Hebrides, having been first discovered by a botanist attached to the United States Exploring Expedition in Ovalau, one of the Fiji Islands, are produced from a decided stem and form a miniature Tree Fern. This stem is of a slender nature, being seldom more than  $1\frac{1}{2}$  inches in diameter, although it reaches 2 feet in height, and the fronds, which attain 2 feet in length, are about 16 inches wide at their broadest part. This species also reproduces itself true from spores.

To the above may be added several very handsome varieties, all of which were raised in Messrs. James Veitch and Sons' nurseries. In

*T. INTERMEDIA* we have a robust-growing and beautiful form which, as may be gathered from a note in Hooker's "Synopsis Filicum," p. 428, also seems to have made its appearance spontaneously in New Zealand. It is intermediate between *T. superba* and *hymenophylloides*, agreeing with the latter in the cutting of the leaflets, but the shape of the fronds is much more that of *superba*, the stalks being densely covered with short woolly hairs.

*T. PLUMOSA* is a very pretty form of compact, dwarf habit, and of a pale green colour when young. It somewhat reminds one of *Todea intermedia*, but the fronds, which are shorter and more egg-shaped than those of that variety, are borne on stalks which are also wanting in the woolly nature which is peculiar to that plant. It is singular that a considerable number of plants of identical character, but differing from the supposed parent, were then obtained from one sowing of *T. superba*. These can only be supposed to be accidental hybrids, brought into existence by the casual intermixture of spores of some other *Todea* with those which were purposely sown. I am further inclined to believe in this theory on account of the barren character of these mules, which, though producing great quantities of spore cases, have never been known to have produced any possessing germinating powers, so that this form is getting gradually exhausted. The same remarks respecting the raising at one time of a quantity of seedlings of identical character and proving barren afterwards apply with equal force to the most beautiful of all home-raised hybrids or varieties,

*T. GRANDIPINNULA*. A most remarkable plant, as much on account of its production as on account of its distinct appearance and of the great beauty of its handsome massive fronds, which are undoubtedly the most transparent of the whole genus. As it has been stated previously, it is so very similar to *T. Moorei* of Baker, that I consider the reproduction of Thomas Moore's description of the plant and the comments he published when it first made its appearance especially interesting at this juncture. Although raised several years before, it was not until 1886 that this lovely plant was put into commerce. In the *Gardener's Chronicle* of June 12 of that year, p. 752, Moore says:—

This handsome Fern sprang up in one of Messrs. James Veitch and Sons' houses, under conditions that render it probable it may be of hybrid origin; in fact, it originated in the close neighbourhood of *T. Fraseri*, which had been standing in company with *T. hymenophylloides*, and several other distinct forms were noticed among the batch of seedlings which sprang up in this position, most of them being of a semi-depauperated character. The present, however, proved to be from the first a fast grower, with a singularly leaty development, which gives to it an aspect quite unlike that of any other known species or variety of this remarkable genus. The obvious and characteristic peculiarity of the plant is the broad leafy aspect of the fronds, in which both pinnae and pinnales are very much overlapped at the edge in consequence of their free growth, both of them being broad, egg-shaped in form, and unequal in development, so that both fronds and pinnae are irregular and unsymmetrical in outline. Whether it be regarded as a hybrid form, with the parentage above suggested, or whether it is simply a foliose sport from *T. hymenophylloides*, which may possibly be

the case, it is a novelty for the Fern house, and one deserving the full appreciation of the cultivator.

To the foregoing remarks I may add that under good culture and the special care of Dr. J. N. Winter, of Montpellier Road, Brighton, the fronds of this lovely plant have attained considerably larger dimensions, and it is also a great pleasure to know that, though exposed to the effects of frost during last winter, Dr. Winter's magnificent plants of *T. grandipinnula* have not suffered in the least from it.

Several other varieties, presumably issue from *T. hymenophylloides*, *Fraseri* and *Wilkesiana*, have also been raised at the Chelsea nurseries and grown there into goodly-sized plants. The group of eighteen thoroughly distinct forms exhibited by Messrs. J. Veitch and Sons at the great Fern conference held at Chiswick in 1890 was intended to show the predisposition to variation possessed by the subjects raised from spores, and in that respect it stood as a unique feature, for some of the plants showed very strange departures indeed, some being depauperated, while others had all their pinnae terminated by a tail-like process. Others, again, had their fronds normal in size and shape, but their pinnae were bitten off, and the most noticeable character in the majority of cases was in the nature of the stems, which were mostly of the *Wilkesiana* type, clear and slender. These have never been either named or described, because, although they produce great quantities of apparently fertile spores, none of them possess the power of reproducing themselves, and as it is the only mode of propagation possible with *Todeas*, these various and distinct forms cannot be increased.

## THE ROCK GARDEN.

### XIV.

AUGUST 15.—Genial sunshine has come again after many rainy days, and though many of the rock garden plants suffered from the wet, the change in the weather has favoured the development of a fresh supply of hardy flowers.

#### DWARF ROCK PLANTS FLOWERING EARLY IN AUGUST.

One of the prettiest little rock plants now blooming is *Acena microphylla*. It seems to grow anywhere without trouble, and makes an effective fringe for rocky steps or a neat carpet for stony banks where it can spread out its prostrate shoots covered with tiny bronze leaves and display its globular heads of crimson spines. *Androsace Leichtlini* with its crimson-eyed white flowers seems to last in bloom even longer than its beautiful parent, *Androsace lanuginosa*, and both certainly go extremely well together. *Alyssum spinosum* is a valuable rock plant. Most of its congeners flower in spring only, but this variety is ornamental all the year round, and even at mid-winter its compact habit and tiny silvery leaves are decidedly effective, while now the charm is enhanced by numerous white flowers. An excellent blue flower is the late-flowering *Forget-me-not* (*Myosotis Welwitschii*), of which I noticed a good plant still in full bloom in early August on a rockwork in Sussex; it has very slender trailing shoots, which, like the leaves, are covered with minute hairs. The flowers are azure-blue and very effective. In the same rock garden I saw *Pelargonium Endlicherianum*, which has showy deep rose-coloured flowers and plicate reniform leaves each from 2 inches to  $2\frac{1}{2}$  inches in diameter. This is the only *Pelargonium* which is hardly out of doors. The plant which came under my notice is about

a foot in height and very effective. *Convolvulus mauritanicus* is now flowering in Essex, Sussex, and in the west, and its bright blue flowers are a great ornament, especially where the plant is treated as it should be, *i.e.*, planted on an elevated position where its pendent shoots can droop over large stones. *Scabiosa Parnassi*, with its silvery grey leaves and light pink flowers, makes a good companion to the former. It will grow almost anywhere, but is never so effective as when planted on sloping ground in the full sun. That noble yellow Rockfoil, *Saxifraga Hirculus*, has finished blooming in most places in the west, but in the eastern counties I noticed several plants flowering to perfection in moist half-shady places, especially in Sussex and Surrey. Of dwarf Campanulas blooming early in August—or perhaps, more correctly speaking, still in bloom—I may mention *Campanula pelviformis*, *C. rotundifolia*, *C. Hosti*, *C. H. alba*, *C. rhomboidea alba*, *C. isophylla*, *C. isophylla alba*, *C. Zoysi* and *C. excisa*. *C. isophylla* of course looks best hanging down over stones. *C. Zoysi* suffered much last season, probably more from the rains in autumn than from the severe cold. In several places in Devon it has been killed altogether, but I noticed a fine batch early this month in a rock garden in Essex, where it was growing in very light soil and sheltered by a large projecting ledge of rock. It has erect stems about 5 inches high, each bearing several bell-shaped pale blue flowers of very distinct appearance. *C. excisa* is still flowering at Kew. It has been very appropriately named, for its corolla is so deeply cut as to have an almost artificial appearance. *Silene armeria* sows itself when once established, and very showy are its bright crimson blooms, enlivening the rocks at a time when bright flowers generally are beginning to get scarce. It makes a capital contrast of colour with the bright yellow *Inula ensifolia*, which is very dwarf and bears large showy flowers. *Linaria anticaria* is now blooming abundantly for a second time, and its white, dark spotted flowers associate well with the purple *Linaria alpina*, which is also still in bloom. Useful carpeting plants for a bog bed or other low damp place are *Pratia angulata*, *Lysimachia nummularia aurea*, and *Erodium Reichardi*, all of which are now in bloom. *Pratia angulata* also goes by the name of *Lobelia littoralis*, and its white flowers resting on a dense carpet of tiny green leaves are very attractive. *Erodium Reichardi* also has small leaves and white flowers, but it spreads but very slowly, while the golden *Lysimachia*, which has yellow leaves as well as yellow flowers, expands rather rapidly. An *Erodium* suitable for a drier position on more elevated ground is *Erodium supracinereum*, with Fern-like divided silvery leaves and drooping pink flowers. One of the latest flowering *Dianthus*es is the variety now blooming at Kew under the name of *Dianthus versicolor* (Russia); it has a semi-prostrate habit, and its magenta-crimson flowers are further enhanced by a dark ring in the centre. Here I must also mention *Dianthus Atkinsoni*, although it can hardly be called a dwarf rock plant. I noticed a beautiful plant of this variety early this month in a Sussex garden. The erect flower-stems are 18 inches high and bear numerous flowers of the most brilliant blood-red colour, and quite the size of a florin. The petals are serrated at the outer edge and are as broad as they are long. It is a great pity that such a lovely plant should be so scarce and so difficult to obtain.

In conclusion, I would mention among dwarf rock plants for early August the pretty little *Hypericum nummularifolium*, with almost

Cotoneaster-like foliage and handsome yellow flowers; the native *Frankenia levis*, which forms an excellent little cushion studded with small pink flowers; *Wulfenia carinthiaca*, which has large leaves and purplish blue flowers; and *Trachelium rumelicum*, with light blue flowers.

MEDIUM-SIZED AND TALL ROCK PLANTS  
FLOWERING EARLY IN AUGUST.

Plants of medium size do not seem to flower abundantly just now, and among those which have come under my observation I will mention only the following: *Spiraea filipendula* fl.-pl., *Sedum populifolium*, *Erigeron alpinus*, *Diets Huttoni*, *Zauschneria californica*, *Ononis rotundifolia*, *Caltha leptosepala*, and *Geranium Wallichianum*. The *Spiraea* mentioned is too well known to need any further comment. *Sedum populifolium* is a decided acquisition on account of its being so very unlike any other *Sedum*. Its pale pink flowers are set off by peculiarly shaped, Poplar-like leaves, and it makes an effective plant for a prominent position on high rocks. The yellow Iris-like flowers of *Diets Huttoni* form a good contrast to the mauve-purple blooms of *Erigeron alpinus* or to *Ononis rotundifolia*, with leaves resembling those of Birch and bright crimson flowers. In a damp swampy place the white Marsh Marigold (*Caltha leptosepala*) is now at its best, while in positions that are dry and sunny few plants do better than the blue *Geranium Wallichianum* and the brilliant scarlet *Zauschneria californica*. The latter requires plenty of room and must be kept quite separate from rocks on which small alpine are growing.

Of tall plants for background work or for forming a kind of connecting link between the rock garden and the shrubbery, the following are now in bloom: *Chelone barbata*, scarlet; *Galega officinalis*, lilac; *G. o. alba*, pure white, and *Gypsophila acutifolia*. The last, by the way, has its white flowers thinly scattered in large panicles growing 5 feet high, and is an excellent plant for cutting and mixing with flowers for home decoration, for which it is still better adapted than the well-known *G. paniculata*. I will also mention *Rudbeckia purpurea*, purple; *R. Newmani*, bright yellow; *Helenium striatum*, brown, with yellow stripe; *Inula bifrons*, yellow; *Eryngiums* of sorts, blue; *Onopordon acanthium*, purple; *Cichorium Intybus*, blue; *Digitalis grandiflora*, yellow; and *Campanula bononiensis alba*, white.

Exeter. F. W. MEYER.

(To be continued.)

ORCHIDS.

DURATION OF ORCHID FLOWERS.

THERE are a few Orchids, such as *Stanhopeas* and several others, the flowers of which are very fleeting, but the majority of the family are among the most durable and long-lived of any plants. Take the *Cymbidium*, for instance. It is not uncommon for the flowers of *C. Lowianum* to keep fresh for three months, while those of *Cypripediums* last a very long time if not bruised or wetted or fertilised either by insects or artificially. It is in only too many places the rule to allow the flowers to remain on the plants too long, and although advised to the contrary, many amateurs and others still persist in this. It is needless to dwell upon the harm done to the plants by this over-flowering, for not only has it been often decried by writers in THE GARDEN, but it is easy for anyone who observes the plants

to see the mischief for himself. A frequent query is, how long should the flowers remain on such a plant? and perhaps an *Oncidium* or *Odontoglossum* is indicated. In conversation recently with a successful amateur cultivator this subject cropped up, and he complained that while writers advised cutting the flowers sooner than is usually done, they gave no hint as to how long the various species may carry their blossoms with impunity. There is perhaps some truth in this, but the fact must not be lost sight of that here is a capital opening for the old adage, that circumstances alter cases. In order to say how long a plant may safely flower it will be necessary to consider first of all the health of the individual plant, the atmospheric conditions of the house it is blooming in, and the relative number of flowers it is carrying in proportion to the size of the pseudo-bulb. Frequently semi-established plants or those in about their second season's growth throw up large vigorous spikes. The plants have perhaps been well treated, grown in a moist and well-considered atmosphere up to the time the flowers are opening, when they are taken to a dry flowering house or living room. The drying atmosphere combined with the heavy strain of flowering while yet the plant has only a few roots will soon be apparent, and the spikes cannot with safety be left upon such a plant, say, of *Oncidium tigrinum* for a week or ten days. On the other hand, supposing the plant had been well established in its pot and the house in which it was blooming kept slightly moist no harm would accrue if the flowers remained for twice that length of time. Plants that are weak and debilitated from whatever cause ought not to be allowed to carry many flowers or for any length of time. There are many species that, if in fairly good health, may always carry their blossoms until they fade provided they are large or medium-sized specimens of their respective kinds. The labiate group of *Cattleyas* may be noted as instances of this, few if any of them carrying their blossoms long enough to do any harm. The flowers of *Cypripedium*, on the other hand, unless the plants are exceptionally strong, should usually be cut after they have been open a month. This need not be taken as applying to the ordinary varieties of *C. insigne*, *C. villosum*, or similar kinds, but to those that one is more particular about and all valuable or rare kinds. The blossoms last nearly as long in water, though they lose some of their colour. The beautiful little *C. Schlimi* is often weakened by its continuous flowering, though this is not owing to the time the individual blossoms last, but the number that are successively produced. The pale yellow tinge in the foliage of plants that have been long in flower is indicative of the waste that is going on to maintain the numbers of blossoms that everyone admires, and it is really surprising how quickly this gives place to a healthy green hue when the spikes are removed and the plants well watered. The flowers of *Cymbidium*, as mentioned above, last a long time. Although they are large and fleshy, I have never known any harm done by leaving them on provided the roots are kept supplied with water and the atmosphere right. The majority of *Dendrobium* flowers, again, may be left until they fade, the pseudo-bulbs being fully able to stand the strain. There may be instances where it would not be advisable, but as a rule it is quite safe. Perhaps the most easily injured of all Orchids are the *crispum*, *Forbesi*, and *Marshallianum* types of *Oncidium*. Take any of these and compare the size of the spikes and quality of flowers with the pseudo-bulbs that have to sustain them, and the reason is at

once apparent. Not only this, but they are usually weakly-rooting subjects, and can therefore only be allowed a modicum of compost in comparison with the Orchids noted above. From ten days for weak plants to a fortnight for stronger ones is long enough to leave the flowers on, and when one considers the advantage it is to the plants, there need be no compunction felt as to this, for have we not the thought of next year's flowering to console us for the shortening of this season's display. Many others may be mentioned, but as the repetition of names becomes somewhat tedious, perhaps these will be best referred to when treating of the various kinds separately.

H. R.

**Odontoglossum cordatum aureum.**—There are many varieties of this plant of a mediocre quality, while others are very beautiful. The pretty form mentioned above can certainly be classed among the latter. The sepals and petals are light creamy yellow, becoming very pale towards the tips; the lip is wholly of a pure white. This plant is of very easy culture, thriving under the same conditions as *O. maculatum*. The compost must be used in a rougher state than for some kinds, and the pots may be rather larger in comparison with the plants. Plenty of water is needed all the year round, and the plants must be kept free of the soft brown scale that frequently attacks them. The type is a very old Orchid, having been introduced as far back as 1837. It is a native of Mexico and Guatemala.—C. H.

**Lycaste plana.**—All the *Lycastes* are useful free-flowering plants well adapted for culture by beginners, and *L. plana* is no exception to the rule. The flowers are somewhat variable in colour, those of the type having light red sepals and pure white petals blotched with crimson. The lip is small with rosy pink spots on a white ground and each flower measures from 3 inches to 4 inches across. The best place for this Orchid is with the *Odontoglossums*, and I lately saw some fine pieces just throwing up their spikes in a warm greenhouse devoted to *Fuchsias*, *Begonias* and the like. It may be potted in two parts of peat fibre to one each of Sphagnum and loam, adding a little charcoal and potsherds. Good drainage is necessary, as the plants require an ample supply of water at all seasons, but especially while growing freely. It is a native of Bolivia and was introduced more than fifty years ago.—R.

VANDA CERULEA.

As the earliest plants of this beautiful Orchid begin to flower it is interesting to note the variation in colouring. The size and shape of the blossoms, too, vary, and whatever beauty lies in the starry, narrow-petalled forms, I consider the broad overlapping segments infinitely superior, especially if accompanied with a deep colour. In some of the paler forms the specific name seems misapplied, especially when first open; after they are fully opened a faint blue colour appears, but at first they are nearly pure white. The better forms are of a beautiful sky-blue and are very attractive.

The culture of this Orchid cannot be called difficult, yet several points require careful attention. A free circulation of air, without chilling the plants by cold draughts, is of great importance, and while requiring abundance of atmospheric moisture, the growth will not be satisfactory in the cool or *Odontoglossum* house. Here the light is too much subdued during the summer months, although if kept at about 50° during winter, or even a little less, the plants will be quite happy at this season. While resting the plants must not be dried at the roots, for these are active much later in the season than those of many other species. Watchfulness is the great secret in growing *V. cerulea*.

It is easy to tell at a glance whether or not the plants are happy, and if they do not thrive in one place they must be shifted to another until the most suitable position is found. Here no Orchid gives less trouble; it is grown close to the front ventilator in the Cattleya house, and all through the summer a little air is left on night and day. The plants are only shaded from the brightest sunshine, which would, if allowed to burn the foliage, greatly weaken the plants. If gradually inured to sunlight it is surprising how much of it many Orchids will stand, and this fact is a great argument in favour of early ventilation. If the air is admitted early enough to dissipate the night moisture before the sun shines on the foliage, this will not be so likely to injure it as when the temperature rushes up quickly. *V. cerulea* is best grown in pots with perforated sides or in baskets, as the roots delight in copious supplies of fresh air as well as water, which in this form of pot passes away quickly. Clean Sphagnum Moss, lightened by the admixture of charcoal or ballast, will be found a good rooting medium, and the pots may be a little more than half-filled with drainage. During hot weather and when drying winds prevail, frequently damping between the pots and occasionally over the foliage must be resorted to in order to keep up the requisite amount of atmospheric moisture. The Sphagnum must be allowed to grow freely about the base of the plants, as it will indicate with certainty the state of the roots as to moisture. *V. cerulea* is an old plant in cultivation, but owing to the number that have been killed by ill-treatment, it has not become so common as many others until within the last few years. Its culture now being better understood, it has become more plentiful. It is a native of the Khasia Hills, whence it was introduced in 1849.

**A curious Lady's Slipper.**—I herewith send you a flower of *Cypripedium barbatum* which might interest you. It has only one sepal (situated at the bottom, behind the pouch, instead of at the top), and one petal in the place of the top sepal, both being well developed.—X.

**Cypripedium Saundersianum.**—This fine plant is amongst the rarest and best of all hybrids. It is a strong-growing plant and the foliage is a good deal like that of *C. Schlimi* (one of its parents), but larger and more vigorous. The dorsal sepal is white, with stripes of green and purple, the petals wavy, light purple, while the pouch is rounded in front, large, light purple, with deeper spots. It was raised by Mr. Marshall, of Enfield, and first flowered in 1886. Its parents are *C. caudatum* and *C. Schlimi*.

**Grammatophyllum Rumphianum** is now a striking object in the Orchid house at Kew. Two plants of this variety are in bloom, each bearing one very long spike and carrying a mass of flowers. One spike has forty-nine blossoms, and the other forty-seven. The flowers, nearly circular in shape, are each about 2 inches across, and the colour is a chocolate-brown on a greenish yellow ground. A great recommendation of this variety is its comparatively small size. The plants in question are in baskets about 6 inches square and the growths of quite moderate dimensions, so small as to surprise one after seeing the imposing flower-spike.

**Miltonia spectabilis Moreliana.**—This superb Orchid is now in flower and makes a fine show at this somewhat dull season for Orchids. It closely resembles the type in habit and shape of flower, but in colour is far superior to this grand old Orchid. The flowers are produced singly on the scapes and are each from 3 inches to 4 inches across. The sepals, petals and lip are all deep rich purple, the lip being the lightest in colour, but veined with a deeper tint. The flowers last a long time in perfection. A shady position near the glass in the Cattleya house suits this Orchid

well, and it may be grown in shallow wooden baskets or on rafts in a compost consisting of good peat and Moss.

## GARDEN FLORA.

### PLATE 1030 CYCLAMEN PERSICUM.

(WITH A COLOURED PLATE OF, 1, VULCAN;  
2, BUTTERFLY.\*)

THE handsome forms of the Persian Cyclamen now in cultivation render it perfectly inexcusable if any growers still cultivate the older kinds with both smaller flowers and paler colours, as well as a less vigorous constitution and proportionately less freedom in flowering. Those now forming the subject of the coloured plate are of the very finest selections in their respective colours. Of Butterfly (white) it may be safely stated that no finer pure white variety has yet been placed in commerce, whilst in the form of the flowers, with the broad overlapping petals and great profusion of bloom, it is unsurpassed. The flowers are borne upon stout foot-stalks, which need no support when due care is taken to prevent them drawing up too slender. The foliage alone of this particular variety is a picture in itself, with its beautifully marbled venations and blotches. It is, in fact, the ideal of a pure white Cyclamen. Vulcan, on the other hand, forms quite a contrast in point of colour, being of an intensely deep crimson, with more of a maroon tint with age. This variety also has the other good qualities of the preceding, with less distinctive, but none the less beautiful, markings in the foliage. Under artificial light its colour is very rich, making it a most valuable plant for all indoor purposes throughout the Cyclamen season. I never remember to have seen this particular shade of colour so intensified in any other variety. It is important to note that these beautiful forms are both reproduced perfectly true from seed. These, with other remarkably fine varieties (including the giant forms), may be seen in admirable condition at Messrs. Sutton and Sons' nurseries, Reading. The mode of culture there adopted will be found at page 379 of the last volume of THE GARDEN, June 1, 1895.

Another well-known grower—Mr. W. Warren, Worton Gardens, Isleworth—sows the seed the first week in June in pans 1 foot square, with plenty of crocks for drainage. The pans are then placed in a one-pipe pit, which is covered with mats to keep it dark and kept at a temperature of about 75° Fahr. The pans are daily looked over to see that the soil does not become dry, as is often the case at the sides. In about six weeks the young plants appear; the pans are then taken to a greenhouse and placed as near the glass as possible, damped morning and evening and shaded from the sun. These few hints are taken from a paper read by Mr. Warren before the R.H.S., January 13, 1891, and published in the journal of the society. Full details of culture are therein given.

The fact of Mr. Warren sowing the seed as early as June should not on any account deter growers from at once proceeding to do the same. Many do in fact prefer to sow in September and October. Cyclamen seed is always offered in the spring seed catalogues, but on the other hand it is not always made so prominent a feature in the autumnal bulb catalogues, wherein

\* DRAWN FOR THE GARDEN by H. G. MOON at Messrs. Sutton's, Reading, March 1, 1895. Lithographed and printed by Guillaume Severeys.
